...de W2NSD/1

Wayne Green

Last month we carried Ken Sessions on the masthead as the FM editor. This probably needs some explanation. Ken (K6MVH), as you may know, has been the editor of the FM Journal for the last year, working in conjunction with Mike (WA8UTB), the publisher. It is easy to go overboard on this sort of thing, as the publishers of many past amateur radio magazines will attest. At any rate Mike and Ken agreed to split up, with Mike continuing the magazine as long as he could alone. Ken wrote to me and offered to run an FM department for 73.

Having just returned from a splendid demonstration of the joys of FM and the excitement of the repeater systems while visiting with Tom Nelson W6QGN, I jumped at the offer.

Ken, in the meantime, had pulled up stakes and moved from California to a job editing Electronic Packaging and Production magazine in Chicago. I called him a few times about some FM articles we had in the works and my good impression of him gained at the Saroc convention back in January was reinforced. Would he be interested in coming with 73? I didn't have much money to offer, but I did have a job that is about as much fun as a job can be for a dedicated ham, and New Hampshire is a fabulous place to live. So I called Ken and though it meant a substantial cut in salary, he quickly agreed to make the move. Since he had been working at EPP for just a few months they were a bit put out by the sudden change.

A couple of weeks later, Ken, his wife and seven children (count 'em–7) and a van load of ham gear (and furniture) arrived. Fortunately I was able to locate a nice home for him less than a mile from the 73 headquarters.

Ken will be running the editorial end of 73, while I tend to increasing the circulation, getting around to a few conventions, talk to a few clubs, maybe get off on a short DXpedition or two, work on plans for 73 to eventually go public, get Radio Today into gear, help with the new junior op that is due about the time this goes to press, work on plans for several other new magazines, and perhaps run ski classes for the 73 staff on bright snowy mornings.

Exit the Youth Forum

The Youth Forum in the October issue didn't work out too well, everything considered. This was the brainstorm of Ralph Irace WA1GEK, a 17 year old with more than the average amount of drive.

Ralph turned up here last July and wanted to do something about getting more teenagers interested in amateur radio. He felt that both 73 and Radio Today could help with this and he wanted a job with us. Being extremely shorthanded, I agreed to give him a trial proofreading articles as an editorial assistant. After a few days it was obvious that this was a mistake. His moods were mercurial, running from virtual catatonia to great agitation. Frankly, he scared most of the girls here and my wife was truly frightened. I laughed at her preposterous worries. I suppose that I should have known, for I laughed at her when she tried to warn me about Don Miller.

At any rate, after a couple of weeks Ralph went away. Shortly thereafter I received a fantastic letter from him saying that he had made copies of many of the documents here and would use them against me unless I came to terms with him. Since there is absolutely nothing here to hide, none of us could figure what could be in his mind or why he thought copies of old bills and letters would be of value to us or our competitors. I ignored him.

In late October, while I was out in California at the Bay Area hamfest, someone broke into the 73 offices and stole my two rifles, plus who knows what else. Our list of missing items is a long one. I reported the theft and dismissed it from my mind.

Then Dave Mann (Leaky Lines) sent me a clipping from the Hartford Times saying that Ralph Irace was being held for murder. According to the clipping, Ralph and a friend were returning from Florida in early November. The police discovered the body of Wayne Rubenstahl shot three times with a .30 caliber rifle on highway I-91 in Lumberton, N. C. The police there put out a warrant for Ralph's arrest for murder and he was arrested in Richmond, Virginia. The police said they were at a loss for a motive for the murder.

I was dumbfounded.

As I thought about it, I became suspicious, so I called the police in Lumberton to check on the murder weapon. I explained about my two stolen 30 caliber rifles and gave them the serial numbers. Yes, they had the guns and one had been used in the killing.

We have no plans for continuing the Youth Forum that was published in the October issue . . . at least not under the same byline.

I have promised to let Lin check on all employment applications for 73, even those on a short trial, in the future. If her intuition says no, no it is. I know when I am licked.

W2BSP's collection of "cavities."

Single Sideband AM-FM Modulation System

Much has been said pro and con about single sideband in its present form. It is an admitted fact that SSB takes up far less of the radio spectrum than AM or FM. Still when you tune in an AM or FM signal with a proper receiver there is a difference. With SSB as it is now, tuning the receiver is critical and stability of the receiver is very important. When the carrier is sent along as in AM or FM the tuning of the receiver is no problem.

Being an old time amateur and liking AM for so long, when SSB came along I could not warm up to it at all. I always liked to hear all that was going on even if it was on an adjacent channel, beat note and all. It was somewhat like being in a room with a lot of people talking at the same time with all the noise added. Today the adjacent channel is all monkey chatter which is almost as bad as the heterodynes. Sometimes you like to know what your neighbor is saying, good or bad. Tuning a few hertz off and not being able to understand, yet hearing the signal either nasal or guttural is not best for me. Also, how are we going to make use of this SSB in the UHF and microwave regions? You would need the stability of an atomic clock at both the transmitter and receiver. FM has made the deepest penetration into these frequencies. Narrowband FM is being used for most mobile communication, and many improvements have been made over the years.

By now I guess you can gather from the above that I am not happy with SSB as it is and I am not about to chuck the old AM rig that is gathering dust in the basement shack. I am dreaming about the ideal system where the carrier would be sent along with a bandwidth no wider than that required for a single signal the same as CW. If someone sneaks alongside I don't want to hear anything other than his own speaking voice.

So now, to get started and narrow things down, I decided to start playing around with filters. Crystal filters are excellent and everyone uses them, but I wanted a filter that I could tune. Just for kicks I decided to build around 30 mhz. Crystals having a fundamental at 30 mhz are pretty hard to come by, so I decided to investigate the resonant cavity type filter as they are quite easy to make. My first thought was the re-entrant type cavity, so I started to look for one. Down on Newbridge Road there is a water tank about 25 feet in diameter and 100 feet in the air. It looked like it would resonate at 30 mhz. This turned out to be wishful

A sight for sore eyes on the Long Island Expressway.

thinking as it was pretty solidly mounted and I assume that the water department would be a little reluctant to let me borrow it for my experimenting. There is one in Garden City that is nearly round and the spherical type is known to have a Q of around 53,000. Well my hopes started to shrink and I finally succumbed to a smaller cavity like a 55 gallon drum. It was quite a sight seeing my little Bianchina 500 Fiat going down the highway with a 55 gallon drum lashed on the back. I ended up with quite a collection – three 55 gallon, one 30 gallon and one 14 gallon.

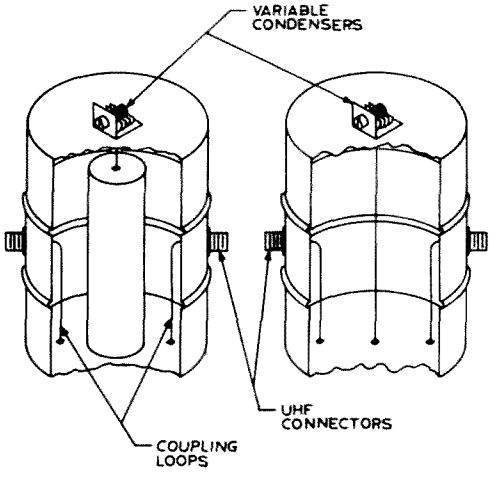

Fig. 1. Drum cavities.

I experimented with two types of re-entrant arrangements. One was made as shown in most textbooks, with a large re-entrant post and capacity loaded and the other with a single wire through the middle of the drum as a re-entrant element. Both of these cavities had a self resonant mode around 200 mhz. With a 100 pf variable capacitor, resonance at 30 mhz was found at about 65 pf. The cavity with a single wire as the re-entrant element had a higher self-resonant frequency as it required less capacity loading.

With the equipment in the shop it was impossible to make accurate Q measurements; to make even comparison measurements a good VTVM was needed, so I had to tap the piggy bank for a VTVM kit. I found this to be a very worthwhile investment and every ham shack should have one. Making comparisons of the characteristics of the two different type cavities showed that the one as shown in the textbook with the large re-entrant element had very little insertion loss, but did not have as sharp a band pass as the single wire job. The size of the coupling loops into the cavities was arbitrarily chosen and no great attempt was made to get a perfect impedance match to both input and output.

There are many things one can do to improve the Q of cavities, such as silver plating the inside or changing the shape and, for stability, temperature control or use of materials unaffected by temperature, etc. Considerable research on resonant cavities has taken place and by searching into past publications one can learn a lot. I was anxious to put them to use and, as far as the other sizes (30 and 14 gallon drums) were concerned, my research ended by finding resonance using the single-wire center element. The 30 gallon drum resonated around 40 mhz and the 14 gallon at 200 mhz using a 50 pf variable capacitor.

Not having a stable signal source on 30 mhz, I decided to build a transmitter that would have a 30 mhz output and when finished with my experimenting, successful or unsuccessful, I would at least have a usable rig on 10 meters. The rig would be FM and as stable as possible.

Having many old-fashioned tubes kicking around, I decided to build a rig as described in an old Radio Handbook (Editors and Engineers Limited. Eighth Edition). The tube lineup is a 6N7 audio amplifier, 6SJ7 reactance modulator, 6F6 electron coupled oscillator, 6K8 oscillator-mixer, and a 6H6 discriminator.

Starting with broadcast components in the electron coupled oscillator, the first frequency is 1.1725 mhz with a 2.345 mhz output. A tripler multiplies the frequency up to the 7 mhz frequency and some of the output signal is mixed with a crystal controlled oscillator. The output of the mixer produces a 465 khz signal, which is fed into a discriminator, thus producing a dc voltage that is used to stabilize the electron coupled oscillator.

Another output of the 7 mhz tripler is then fed into doublers that multiply the frequency up to 30 mhz. (Modern tubes were used for this.) The signal ended up with a 6AQ5, giving enough output to light a small neon. I encountered the usual parasitics and other things and had to back-track many times. Also, listening to the 28 mhz signal, I found it to have considerable 60 hertz hum with no audio going into the reactance modulator. The electron coupled oscillator called for a coil in the filament lead of the 6F6, and the AM broadcast frequencies require quite a few turns. There was a filament voltage drop and, with low voltage on the filament and ac in the coil, some modulation of the carrier was taking place. I decided to put dc on this filament; with good filtering the hum on the carrier decreased substantially.

Now I had an FM signal generator ready for the drums. I connected the output to the input of one of the drums and, using a sensitive meter with a crystal rectifier, I was able to observe the changes of reading as I tuned through resonance. The single wire re-entrant drum tuned very sharply and I was pleased. When tone modulation was applied, the reading went down just as it should. Using an on-off tone at about 2500 hz I found I could tune to both the upper and lower sidebands. I also found that I could get wideband modulation and

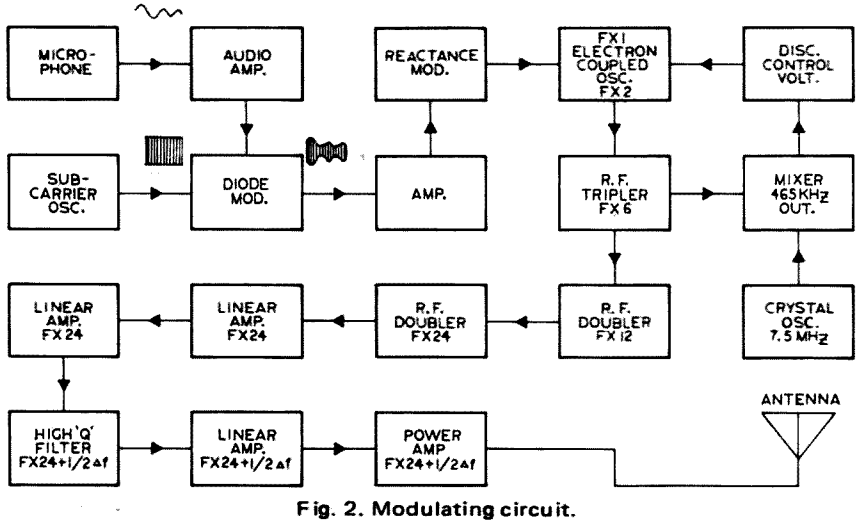

Fig. 2. Modulating circuit.

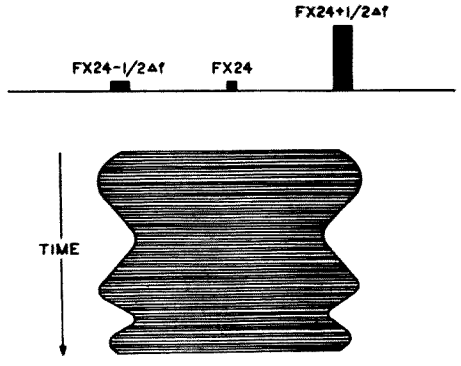
detected sidebands as much as 200 khz away from the center frequency of the FM signal.

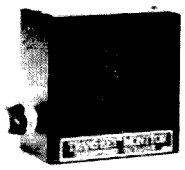
I also found that I could peak the final amplifier to the upper or lower sideband and get an increased signal reading depending where resonance of the drum was tuned. The maximum sideband signal also varied with changes of audio level or deviation. The tone of the on-off oscillator was good when I listened on my old AM receiver and it was quite easy to locate the carrier center with no audio. With very little shielding of the chassis and the bottom plate off there was plenty of rf floating around the shack.

Well now, what will happen with voice and music fed into the system with all this deviation and how much intelligence will get into the filter? I coupled a microphone into the unit and turned up the gain and listened on the AM receiver. All that I could hear was a lot of pops of the high level audio peaks and it sounded very similar to our present sideband without the carrier added. By increasing the deviation there were a greater number of pulses due to more rf getting into the filter, but it sounded pretty awful. None of the low amplitude audio was getting to the filter and at this point I thought of using volume compression and clipping. I saw an article in 73 on a compression amplifier and immediately built one. The output of this was fed into the unit and after a few more days of tuning, testing, and listening to a little less awful sounding signal I proceeded to the local liquor store and bought a bottle of scotch and drank it. This didn't help so I decided to try clipping. I incorporated it in the compression amplifier, using a couple of diodes for the clipping. Now, this made an improvement and with all the distortion created by very heavy clipping I finally was able to understand voice modulation. Music sounded like 2000 cats on an equal number of different sized tin roofs.

After analyzing the situation I found that those low amplitude audio inputs would never make it, or would only when all others were deviated into the microwave region on the upper sideband or back into the audio range on the lower sideband. Then there wouldn't be much left anyway because the carrier would be spread out as if hit by an atomic bomb.

Those low amplitude audio signals needed a little push. Why not introduce a subcarrier that would push those little signals out to the filter, just far enough that they could be heard? The frequency of the subcarrier would be above the audio range and would not be heard. I started immediately to build an oscillator out of transistors and ended up with an oscillator on about 35 khz. I fed this directly into the grid of the reactance modulator mixing it with the audio. Making all the necessary adjustments I listened, but those low audio signals just didn't come through. I then decided to look at the audio going into the reactance modulator on an oscilloscope; sure enough, it was riding up and down with the carrier and not modulating like old fashioned AM should. We needed a better arrangement. I decided to put a diode modulator to work and get good AM modulation of the subcarrier.





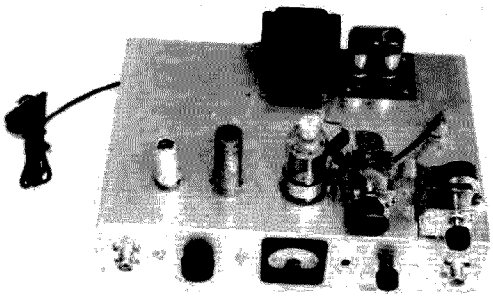


Fig. 3. Carrier, sub-carrier & audio modulation.

This arrangement made a tremendous improvement—so much that not only could I understand what a person was saying but I could also make out the music. The AM receiver I have was not up to receiving this type signal too well, so I needed something a little better. I found an old 30 mhz i-f strip out of a surplus radar in my junk and started to work on it. The strip needed a going over as one of the rf amplifiers oscillated when plate voltage was applied. I installed a ratio detector after the last rf stage and after a

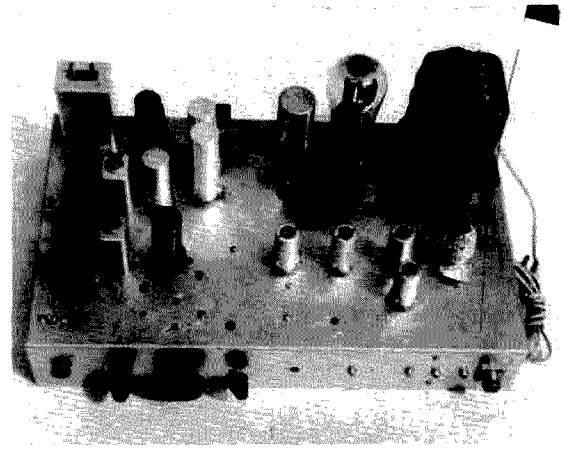
few additional problems I got the strip to work. I lowered the supply voltage, as the strip had quite a bit more gain than I needed to make tests. Using a small transistorized audio amplifier and speaker, I started to listen to the output of the filter. It sounded pretty good.



Linear amplifier.

Now what would happen if the output of the filter were coupled into a final linear amplifier? I decided to build a linear amplifier with a circuit using a 12BY7 driving a 6146. This linear amplifier was built on a separate chassis using two well-regulated power supplies, one low voltage and one high voltage.

After the usual problems with neutralizing and parasitics I found there was insufficient gain and another stage of amplification was required. Also I might point out that for the filter I now had two 55 gallon drums hooked in tandem. This introduced considerable insertion loss and the amount of power output was small, but contained the sharp band-pass characteristics that are needed. Using a 6AU6 to drive the 12BY7 brought the filter output up and drove the power up to a good level. With this additional power I was now able to take the receiver some distance from the equipment and listen to the quality. After listening I became very encouraged and was pretty well convinced that I had a different means for getting a sideband signal that would be pleasant to listen to.

In that this type of modulation as far as I know is not on the FCC list I have not put the system to test on the air. With the proper FCC approval I will give it a try, but in the meantime will continue to use the dummy load for tests.

In that the first unit constructed grew like Topsy, future plans are to build another chassis using better components and newer layout. There is considerable room for experimentation with the system and I also have plans to try using two arrangements having two different subcarriers so as to get a compatible stereo output. This will require a different or double detection receiver.

Main chassis.

Many improvements can be made for band switching with tunable filters. One disadvantage for amateur use is that the filter is at the fundamental frequency transmitted and it has to be good as it is the frequency determinant and must be stable.

In that the system contains both AM and FM and a filter I guess that the best name for it would be Frequency Aperture Modulation, or FAM.

. . . W2BSP ■

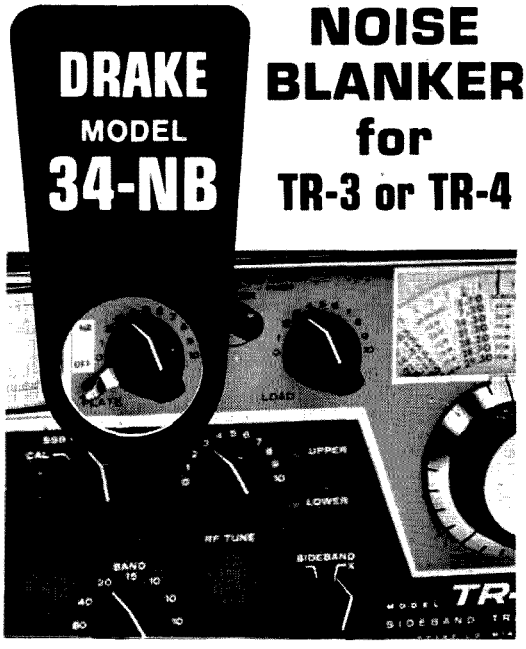
Leaky Lines

Writing a monthly article for a magazine like this is not a lead-pipe cinch. It can be sheer drudgery, tedious and monotonous, because of the limited subject matter. By precedent it has been established, more or less, that publications oriented toward specific activities should confine themselves to those alone.

One's intellect, however, fairly shrieks for variety, above all. For the disciplined, principled view, which always characterizes small and large crusades, demands constant iteration and reiteration. The moral obligation to maintain a concentrated pressure in order to effect a desired change (and it *is* an obligation) demands allegiance to the idea . . . completely and wholeheartedly. Yet, there do exist other things, other matters of fascinating interest, even though they may be less appropriate, or may appeal to be lighter, when weighed in the scale of comparative importance.

It is sometimes necessary to take a look around and consider these lighter topics, in order to preserve a certain quotient of balance in the total equation of existence. For, one-sided, overfervent, hyperintense crusades create one-sided, overfervent, hyperintense bores . . . people who, despite the correctness of their views, succeed generally only in repelling the very ones they are most anxious to convince and convert.

Just to demonstrate that three prohibited examples out of this group, all of which have been pronounced "taboo," may be discussed without provoking anything more alarming than the gray matter, I wish to concern myself with them in this installment of my personal journal. For many years the timid and timorous have studiously avoided any open dialog upon these matters, lest they offend the sensibilities of that huge mass of shadowy, faceless and nameless creatures called "the public."



But this "public" is not merely an amorphous glob of inorganic goop, without volition or the ability to distinguish between common sense and idiocy. The 'public" is composed of individuals, in each of whom resides, if only dormantly, the intelligence to determine for himself the dimensions and limits of decency, propriety, and virtue.

And so, despite the upraised hands and horrified tongue-clucking of all the alarmists who ceaselessly warn of impending doom and disaster, I shall make a few observations and speculations concerning these three unmentionable subjects: Politics, Religion, and if you'll pardon the expression, Sex!!!

Now this, as if you didn't know it, is an election year. And in such periods we seem always

(continued on page 93)

Kill ignition noise
and other strong impulses
with a

Unlike the usual noise clippers or limiters, the 34-NB is an advanced noise blanker which actually mutes the receiver for the duration of the noise pulse. Between noise pulses, full receiver gain is restored. (The receiver AGC is affected only by the desired signal strength, not by the noise at the antenna.) Low level signals masked by noise impulses without the noise blanker can be copied when the blanker is used. The 34-NB is a must for the mobile operator.

HOW IT WORKS . . .

A noiseless electronic series switch is inserted at the output of the receiver mixer. This switch is operated by the output of a special receiving circuit which is tuned to the 9 MHz IF with bandwidth of 10 kHz. The switch opens for noise impulses but closes to allow the signal to pass.

The kit consists of these main parts: 9-NB board (composed of 17 transistors, 4 diodes and circuitry), NBK board, capacitor assembly, switch assembly, lever knob, and miscellaneous hardware.

Available only as a factory installed accessory. Includes noise blanker and transceiver alignment.

Model 34-NB $129.00 Amateur Net

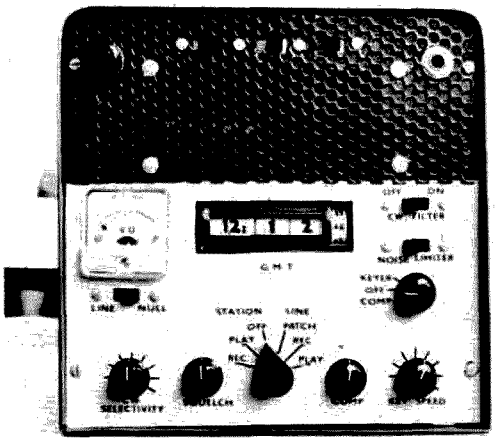
The Transceiver Companion

Peter A. Lovelock W6AJZ
235 Montana Avenue
Santa Monica CA 90403

The transceiver companion is not just another control console; in fact, its application isn't limited to transceivers, and it might well find a place with any receiver-transmitter combination. It started out as a desire to integrate all the associated accessories which surrounded the transceiver in the corner of our apartment living room.



What with a compressor preamp, electronic keyer, phone patch, tape recorder, CW filter, clock and speaker with associated cables, the corner was getting messy and the XYL unhappy. Besides, there was a problem of plugging and unplugging for each mode of operation, and the tape recorder would be more useful if . . . . . !

Thus the transceiver companion evolved to integrate the necessities of a fixed station transceiver, with the one exception of the tape recorder itself. But it took care of utilizing the recorder for various purposes without touching a connector.

Actually this article presents ideas for consolidating the ham station accessories adaptable to the individual constructor's needs. My companion was designed to provide associated functions for my Galaxy V Mark 2, though with a mind to eventual equipment replacement, and the flexibility to work with something else.

So if you use some other equipment and your operating habits dictate other accessories than described, you may well be able to build a companion of your own. It may not even look the same, for you will likely as not want to utilize a housing to match your other equipment. And how many hams exactly copy any construction article?

The heart of the transceiver companion's flexibility is the use of plug-in, computer-

type boards, for all the transistor circuits incorporated. You can buy such boards ready made, or build them yourself. They permit great ease for trying out different circuits, or substituting that better one when it comes along with a minimum of construction change. And they are real great for testing and troubleshooting, or incorporating the occasional modification.

Thus, the companion isn't a static piece of equipment doomed to eventual obsolescence.

Besides the transistorized circuits, other accessories are incorporated in more conventional form. Right now my transceiver companion incorporates the following which, apart from the tape recorder, mike and separate power supply, is everything I use with the transceiver:

(1) speaker, and headphone jack.
(2) low-pass speaker filter to eliminate SSB monkey chatter.
(3) phone patch/tape recording and playback facility with selectable mode.
(4) digital clock.

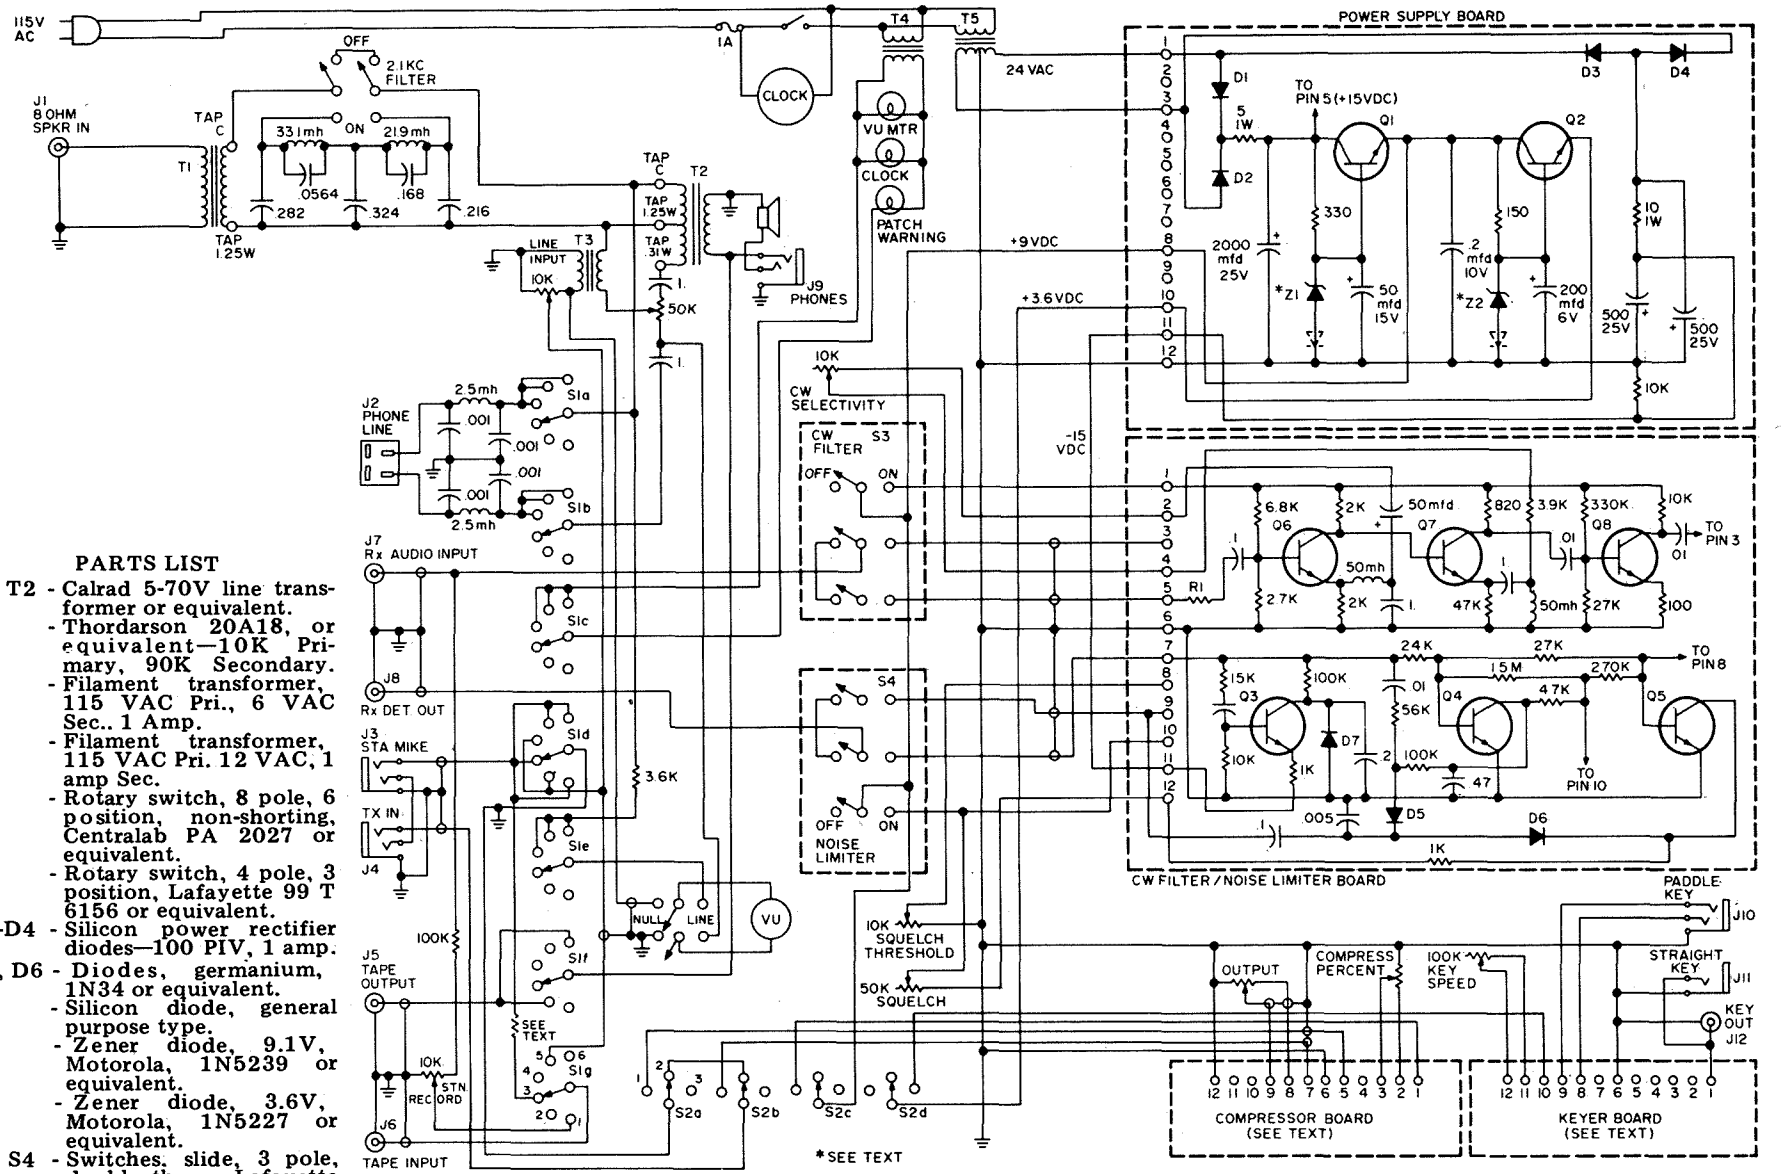


Fig. 1. Schematic.

PARTS LIST

- T1, T2 - Calrad 5-70V line transformer or equivalent.
- T3 - Thordarson 20A18, or equivalent—10K Primary, 90K Secondary.
- T4 - Filament transformer, 115 VAC Pri., 6 VAC Sec.. 1 Amp.
- T5 - Filament transformer, 115 VAC Pri. 12 VAC, 1 amp Sec.
- S1 - Rotary switch, 8 pole, 6 position, non-shorting, Centralab PA 2027 or equivalent.
- S2 - Rotary switch, 4 pole, 3 position, Lafayette 99 T 6156 or equivalent.
- D1-D4 - Silicon power rectifier diodes—100 PIV, 1 amp.
- D5, D6 - Diodes, germanium, 1N34 or equivalent.
- D7 - Silicon diode, general purpose type.
- Z1 - Zener diode, 9.1V, Motorola, 1N5239 or equivalent.
- Z2 - Zener diode, 3.6V, Motorola, 1N5227 or equivalent.
- S3, S4 - Switches. slide, 3 pole, double throw, Lafayette 99 T 6166 or equivalent.

(5) transistorized noise limiter and squelch.
(6) variable selectivity audio amplifier for CW operation.
(7) electronic keyer.
(8) microphone compressor/preamp.
(9) power supply for transistorized circuits.

The entire unit is housed in an 8 inch x 8¼ inch x 8 inch cabinet, taking up just 1/3 cubic foot of space.

Fig. 1 shows the complete schematic of my transceiver companion, and the following is a description of the elements enumerated above:

Speaker

A 6 inch by 2 inch, 8 ohm voice coil speaker was selected because of the excellent response range and convenience of fitting this configuration into the available panel space. This type speaker is available from a number of sources (including a replacement for several popular brand table model TV sets). However, TV manufacturer replacements run around $7.50, while imported makes cost from 89 cents to $1.98. Usually the lower the price, the smaller the magnet and the lower the efficiency. Some imported makes have 3.5 ohm voice coils, requiring use of the 4 ohm tap on T2. (See recommended parts list.)

Low-Pass Speaker Filter

The switchable 2.1 khz low pass filter is a Chinese copy of that described by W3NQN (*QST*, Technical Correspondence, November, 1967). Transformer T1 elevates the transceiver output impedance to the 500 ohm impedance of the filter. T2 matches the filter to the 8 ohm (or 3.5 ohm) speaker. T2 also serves double duty as a component of the hybrid phone patch circuit described below.

This excellent filter circuit provides a maximum attenuation of -60 db at about 2.6 khz, and no less than -40 db at all frequencies above that. It is considerably superior to constant K and m-derived filters in the sharp cutoff above 2.1 khz, which knocks out high pitched "monkey chatter" and heterodynes without affecting speech intelligibility.

The filter on-off switch is therefore not essential as it may be left permanently in circuit. However, since I anticipated using the speaker for other monitoring purposes, the switch was included to permit optional full response range. In addition, it provides a convincing demonstration of the effectiveness of the filter, which has to be heard to be believed.

The filter coils are made from surplus 88 mh toroids by removing turns until the exact values are measured on an impedance bridge. Similarly, the odd capacitor values are built up from standard value units in parallel and measured on the bridge to obtain the precise values shown. Not every ham has possession or access to a high precision bridge, unfortunately. Use of approximate values will result in degradation of performance from the optimum. Therefore, I can't overemphasize the value of borrowing a bridge, or prevailing upon some engineer or technician friend who has one at his disposal, if you plan to use this filter. The results will be worth the effort.

Digital Clock

This was obtained by extricating the works from the plastic case of my former desk clock (Tymeter twenty-four hour clock, Lafayette catalog 40 T 9102). The entire clock movement is assembled on a casting, mounted by two screws to a bottom plate. The plate was removed and discarded, and the tapped holes in the casting utilized to mount it to the companion chassis foundation. Two miniature pilot lamp holders were attached to the numeral mask to provide illumination.

Phone Patch/Recording Switcher

The phone patch is a duplicate of that designed by Katashi Nose, KH6IJ ("An Inexpensive Hybrid Phone Patch," *73*, November, 1965). This circuit permits the use of low-cost transformers and a 50k balancing pot, with impedances widely in variance with the conventional 600 ohms. This results in fantastic losses, but as KH6IJ pointed out, the loss in gain is appropriate when matching a 0 db level phone line to a -55 db mike input. In fact, the "imperfections" of this circuit serve to reduce hum and rf susceptibility, and it works like a charm at a fraction

of the cost for the components of a high grade circuit.

As mentioned above, T2, which is a center-tapped transformer providing two arms of the bridge, also serves the dual function of matching the output of the low-pass speaker filter to the speaker. When this was tried experimentally, it was feared that switching the filter would cause a change in the null balance, but this proved unfounded, and T2 serves its dual role beautifully.

T3, the two 1 mfd capacitators and the 10k potentiometer (TX input level), make up the balance of the patch components. A refinement to the original circuit was the addition of a VU meter which, by means of a DPDT slide switch, can be selected to read transmitter input level for null adjustment (null position) or output level to the phone line (line position). I personally consider the use of a VU meter essential to prevent feeding too high a level to the phone line, which is all too easy if "ear" measurement is depended upon.

Null adjustment is described at the end of this section.

J7 and J8 provide for permanent connection to the mike input and speaker output of a suitable tape recorder. (I use a small transistorized recorder, with high impedance mike input, 8 ohm speaker output.) Phone patch/recording/playback mode switching is provided by S1a-g which is a 4 deck, 8 pole, 5 position, nonshorting rotary switch wired to provide the following functions:

Position 1 - Record from receiver.
Position 2 - Playback to transmitter.
Position 3 - Off (usual position during normal station operation).
Position 4 - Phone patch.
Position 5 - Record from phone line.
Position 6 - Playback to phone line.

While position 3 is denoted as "off," it will be noted that the station mike is connected to the tape recorder input in this position. Therefore, activating the recorder in position 3 will permit recording of transmissions made. If PTT can be deactivated, the station mike can be used for making any recording, such as directional CQs, which can then be played back as often as required to the transmitter input by switching the mode switch to position 2. Alternatively, another station's transmission may be recorded (mode switch in position 1) and then played back for his edification (position 2) or held over for later telephone relay to some third party (position 6).

The mode switching permits flexible utilization of the tape recorder without having to plug or unplug a single connector for any mode.

With a high-impedance recorder input, no loading or gain loss from the station mike is experienced when simultaneously transmitting and recording with mode position 3. However, some transistorized recorders have input impedances which are intermediate, even though they function with a crystal mike. Such recorders may load the mike line and cause significant loss of gain to the transmitter input. In such cases a resistor of 50k to 250k should be inserted in the wire between sections d and g of S1, until no noticeable loss of level to the transmitter can be observed. Tape recorder input level can be compensated by its own gain control.

In mode positions 4, 5, and 6, all of which involve connection to the phone line, section c of S1 activates a warning light mounted in the top left hand corner of the front panel, to remind the operator to return the mode switch to a nonphone line position at the conclusion of this type of operation.

Two 10k pots mounted at the rear of the companion provide preset level adjustment for station receiver output to the recorder, and phone line input to the transmitter and tape recorder.

To adjust the hybrid phone patch balance, first call an obliging friend and have him hold the line. Switch mode to position 4 and VU meter to *line* . Feed a steady signal from the receiver (such as the beat note from crystal calibrator, tuned to approximate a 1 khz tone), and adjust the receiver gain control for a VU reading of 0 db. Switch VU meter to NUL and slowly adjust the 50k balancing pot for null (zero) reading on the VU meter. This first null may appear somewhat broad. Actually the null position

of the pot is quite sharp, but the null is about -40 db, while the VU meter range is limited to about 25 db. It will now be necessary to temporarily crank up the receiver gain in order to feed enough level to the meter to find the exact null adjustment. This must be done as quickly as possible since it means feeding more than the normal level to the line. Once set, the null pot requires no further adjustment unless the companion is connected to a different line—such as when changing QTH. However, it's worth rechecking once in a while, in case the company has modified something at the other end of your line which would affect the balance.

The VU meter must always be switched to line position when using the phone patch, and the receiver gain control adjusted so that VU meter readings do not exceed 0 db on voice peaks. If the switch is left in null position during operation, the VU meter will load the transmitter input and result in severe loss of gain from the phone line. However, during normal, nonpatch operation the null position may be used to provide visual monitoring of the receiver output, since the hybrid circuit is unbalanced when the phone line is disconnected. Thus, actual signal versus noise reports may be given to stations in addition to the traditional S-meter readings. The meter is automatically disconnected in the line position, when the mode switch is in position 1, 2, or 3 to prevent possible damage from high signal levels at the unloaded phone-line switch connections.

In the event your transceiver doesn't permit taking audio from the detector stage, as required by J4 in Fig. 1, an alternate circuit which will permit recording from the receiver is shown in Fig. 2. This involves the addition of a small transformer, T6, with an 8-ohm primary and 500-ohm secondary impedance to match the tape recorder output to the patch line terminals when the mode switch is in position 2.

Noise Limiter and CW Filter

In order to use the noise limiter and CW filter it is necessary to be able to take audio output directly from the product detector and feed input to the audio amplifier of the

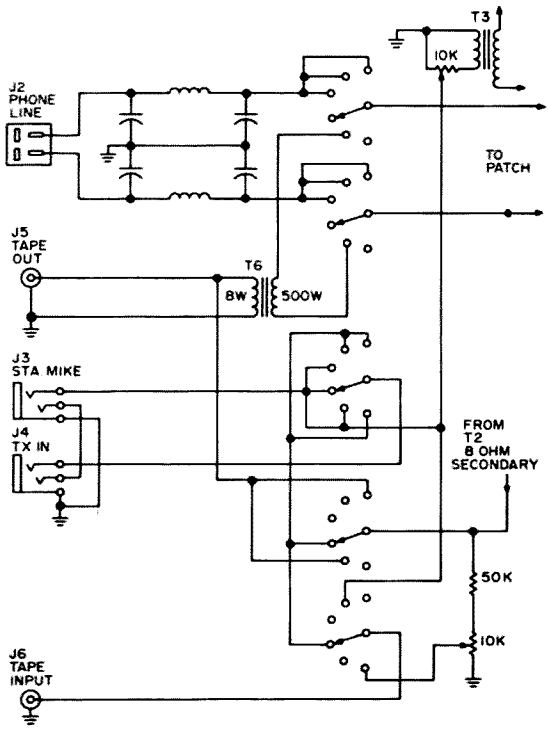

Fig. 2. Alternate circuit for station recording and playback. T6—Miniature transistor output transformer, 600 ohm pri, 8 ohm sec.

transceiver. The Galaxy V Mk2 and the Mk3 transceivers have such a provision built in to accommodate an audio filter manufactured by Galaxy. If your equipment has no such provision it can easily be incorporated by mounting a dual RCA type phono jack on the rear of the unit and wiring the detector output to one jack and the amplifier input to the other, using shielded cable. If you don't care to make such a modification you obviously can't make use of this section.

Both noise limiter and CW filter are constructed on a single plug-in board (see construction section).

The noise limiter is a transistorized version of the popular TNS circuit, comprising Q4 and Q5, and was adapted from a circuit by Tom Kneitel K3FLL ("103 Simple Transistor Projects," John F. Rider Publishing, Inc.). Q3 is an audio derived agc circuit furnishing fast attack, delayed release negative bias, to replace the more common carrier derived avc from an AM detector which this circuit requires to "gate" the squelch action. As with its tube predecessor, this circuit provides a squelch feature by varying the load resistor value in the collector of Q5. The load resistor is a front

panel control, 50k potentiometer labeled SQUELCH. The 10k pot connected to the base of Q5 is for preset adjustment of squelch threshold, and is mounted on the rear bracket. Setting of this control depends upon the exact characteristics of the transistors used, and the input signal level to some degree. To adjust it with signal applied from the receiver, the squelch threshold control should be advanced from zero circuit resistance to a point where no further increase in signal level is observed. Any further advance of the control will result in overdriving the transistor bases with resultant distortion and degradation of noise-limiting action. The adjustment is best made with random noise, and setting slightly below the point of maximum signal may improve noise limiting. At the optimum setting of the squelch threshold control, squelch action will occur at about the midpoint setting of the front panel squelch control.

It should be noted that, for the circuit constants shown, Q4 and Q5 and the diodes D5 and D6 *must* be germanium types. Silicon types will not function with the resistor values shown. Q4 and Q5 may be any audio-type, germanium NPN transistors with an h_{FE} of about 100.

The selective CW filter comprised of Q6, Q7, and Q8 is adapted from a circuit by Jim Fisk W1DTY (*73 Transistor Circuits*, published by 73 Magazine). Q6 and Q7 have a controllable feedback loop between their emitters, which is correctly phase shifted by the series tuned circuits in parallel with the emitter resistors, so that feedback takes place only at a frequency determined by the tuned circuits. The 1 μf, 3v ceramic capacitors and 50 mh coils used in my unit provide a resonant frequency of 700 hz. These values were used because they were available, but other combinations of L and C may be substituted, providing they resonate at a desired audio frequency. However, as the value of L in increased so is the impedance of the circuit, and the feedback control potentiometer will also have to be increased.

The 50 mh coils I used are surplus miniature shielded toroids, and regardless of the value of the coils, toroids are strongly recommended to avoid stray coupling, which will degrade the selectivity of this circuit. The use of high value ceramic capacitors requires matching the values of the components used to ensure that both circuits are resonant at the same frequency, since ceramic capacitors have wide tolerance ranges. If test equipment is not available to match the capacitors, you can try padding each capacitor with smaller value capacitors until regeneration (audio oscillation) occurs with the lowest setting of the 10k potentiometer.

The CW selectivity control varies the amount of feedback between Q6 and Q7 and thus changes the bandwidth. At a point just before oscillation occurs, selectivity becomes extremely sharp with the characteristic ringing of a crystal filter, so that only the slowest speed CW can be copied. The 3.9k resistor in series with the selectivity potentiometer should be decreased or increased experimentally until the circuit is just on the threshold of oscillation when the selectivity control is advanced fully clockwise (zero resistance).

Resistor R1 is provided to attentuate the output of the product detector, which in the case of the Galaxy V was too high for the input of Q6. The value will have to be determined experimentally for the receiver used, but in the case of the Galaxy it is 100k.

The original Fisk circuit included an emitter follower ahead of Q6 to provide input isolation. This stage was found to be unnecessary with the high input level from the Galaxy V product detector, since the 100k series attenuating resistor required to drop the level to Q6 furnished a sufficiently high input impedance to prevent loading the detector stage. If this circuit is to be used with equipment requiring an isolated input, the emitter follower input circuit may be required, and Fig. 3 shows this optional circuit.

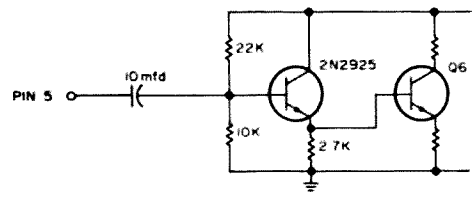

Fig. 3. Alternate input emitter-follower stage for CW filter.

Since the output of Q7 across the 820 ohm load is quite low, Q8 is a simple stage of gain to raise the level to that required for the transceiver audio input.

Jacks J3 and J4 connect to the product detector output and audio stage input via shielded cables. Both the noise limiter and CW filter circuits are switched in and out of circuit by two 3-pole double-throw slide switches mounted on the front panel. One section of each of these switches provides the +9v regulated power required by both circuits. It will be noted that the switches are wired in combination so that the noise limiter is ahead of the CW filter when both are used simultaneously. This is important, since high impulse noise peaks, such as ignition, switching transients, etc., can cause extreme ringing when the CW filter is adjusted close to maximum selectivity. Removal of such pulses can make possible the copying of weak signals through QRM which would be rendered intolerable by high noise impulses.

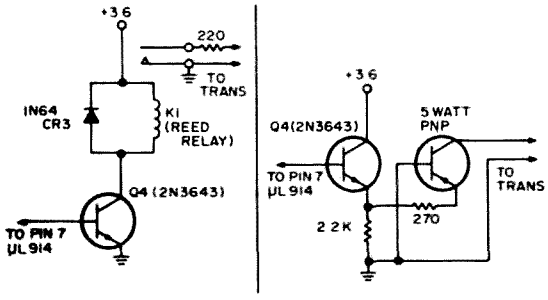

Fig. 4. Power transistor switching output modification for K3CUW keyer.

Electronic Keyer

The keyer board incorporates the circuit of the Micro-TO Keyer by K3CUW (*QST*, August 1967, and *ARRL Handbook*, 1968). Consequently, the complete circuit is not included on the schematic, although external connections to the board are shown. The sidetone oscillator in K3CUW's keyer was excluded since my transceiver has built-in provision, but the board has plenty of room to include the oscillator if required. The only other deviation from K3CUW's circuit was the use of a power transistor, instead of a reed relay, for direct keying of the transmitter. Fig. 4 depicts the incorporation of the power transistor to the Micro-TO Keyer. Just about any PNP 5 watt power transistor will function in this circuit, which is intended for grid-block or low power stage keying.

Compressor Amplifier

A number of circuits have been tried out on this board over the past year, and if you find a compressor useful in your operation, the bibliography may prove helpful. Unfortunately, for proprietary reasons the actual circuit now in use cannot be reproduced here but typical controls and connections to the board are included on the schematic.

Switch S2 is a 4 pole triple throw, nonshorting rotary switch, which switches in either the electronic keyer or the compressor amplifier. A single switch, with center position off, was utilized, since quite obviously simultaneous operation of keyer and compressor is never required. In the off position power is removed from both keyer and compressor, and the microphone is connected directly to the transmitter. When the switch is in keyer position, the microphone is disconnected from the transmitter to avoid unintended modulation.

Power Supply

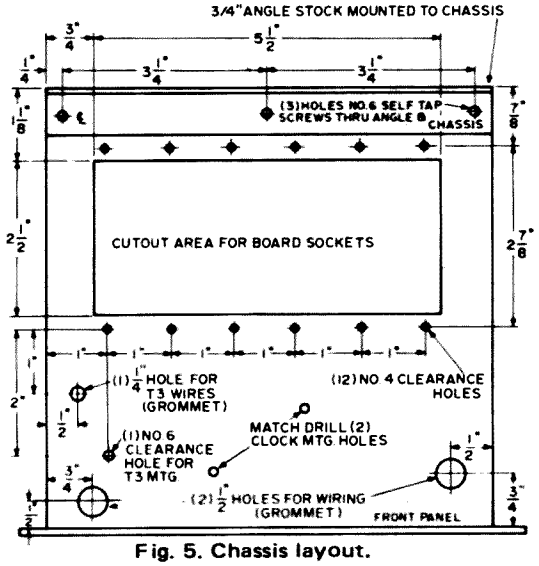
The internal power supply, which furnishes all the voltages for the various circuits, comprises T5 and the regulated power board. T5 supplies 24 vac, center tapped ground to the board. A full wave rectifier consisting of D1 and D2 and associated filtering components supplies +15v to the voltage regulator circuits of Q1 and Q2. The regulator transistors furnish +9v and +3.6v respectively. The +9v supply is used for the CW filter, noise limiter and compressor circuits. +3.6v is used for the electronic keyer. Q1 and Q2 are arranged in series to give particularly stable regulation of the +3.6v, since the keyer current requirements are quite heavy during "key down," and any voltage fluctuation causes keying speed variation.

A word about the zener diodes Z1 and Z2 is in order. If 9.1 and 3.6 volt zener diodes are used in these positions, the output voltages will be the zener voltages less the 0.6 volt base to emitter drop in Q1 and Q2,

resulting in outputs of 8.5 and 3.0 volts. But zeners, like any components, are subject to tolerances so the voltages may be slightly higher or lower. While the +9v circuits aren't too critical, the +3.6v required by the keyer is, and should be adjusted as closely as possible. Too low a voltage will result in inability to obtain the lowest keying speeds, while the voltage should not exceed much over 4 volts to avoid damage to the integrated circuit components. Voltage adjustment can be attained by selecting zener diodes with high tolerance values. However, an easier method is to add forward biased silicon or germanium diodes in series with the zeners. The drop across the diodes will add to the zener voltage -0.6 volt for silicon diodes and 0.3 volt for germanium diodes. Having first assembled the circuits with the zener installed alone, measure the output and note the drop below the desired output. Then add silicon or germanium diodes as required to bring the voltage up to the proper value. Since the voltage drop across the forward biased diodes in constant within their current limitations, they have no effect upon the zener regulating capability. Both zener and regular diodes should be rated at 1 watt.

D3 and D4 provide full wave rectification to supply -15v unregulated, utilized by the age control circuit Q3 for gating the squelch.

+15v unregulated is also available at pin 5 of the board, though not currently utilized in my companion.



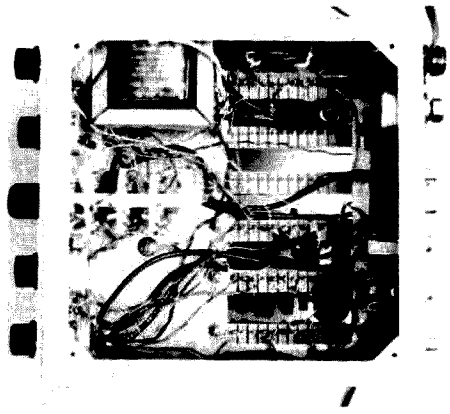


Fig. 5. Chassis layout.

Construction

For those who may want to duplicate my transceiver companion, **Figs. 5** and **6** show the chassis and front panel layouts with major cutouts and hole dimensions and locations. Not all component mounting holes are shown due to the likely substitution of components with dissimilar mounting requirements.

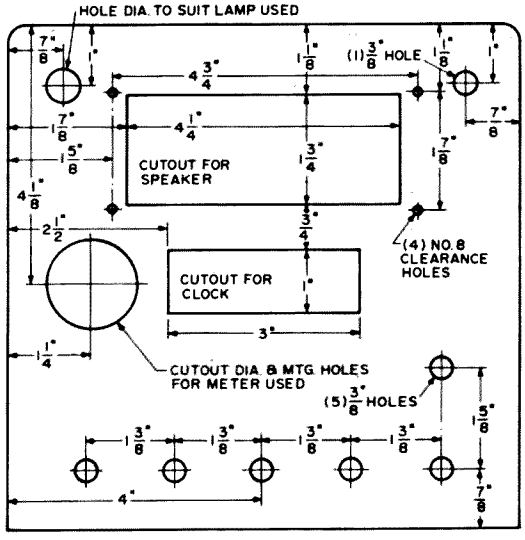

Fig. 6. Front panel major layout dimensions.

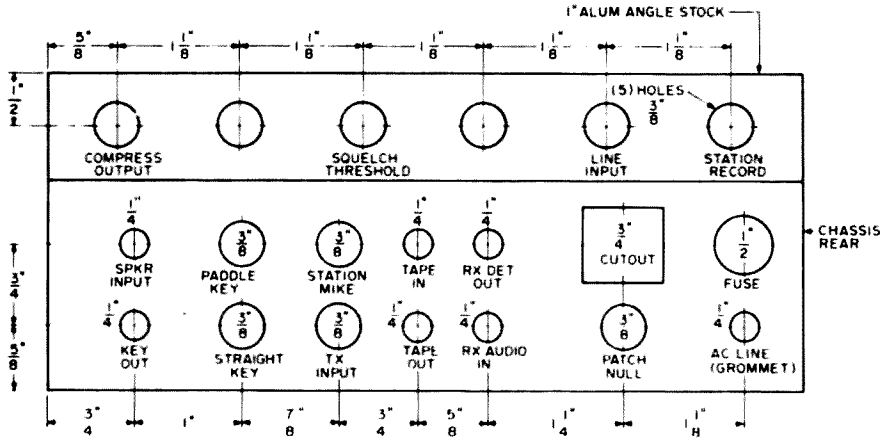
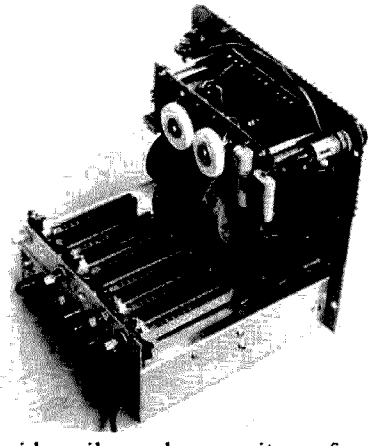
The front panel is part of the 8" x 8¼" x 8" cabinet, (Premier Compact Cabinet, Lafayette stock nunber 12 T 8436). Premier Metals manufactures this type of cabinet in various dimensions, for those who may have different requirements. The speaker grill was fabricated from a piece of perforated metal stock. Bottom part of the front panel was finished with two spray coats of light gray lacquer. Lettering and dial markings were applied with Letraset instant lettering, and the entire section given two finish coats of clear acrylic lacquer to protect the lettering. Top portion of the panel and the grill were





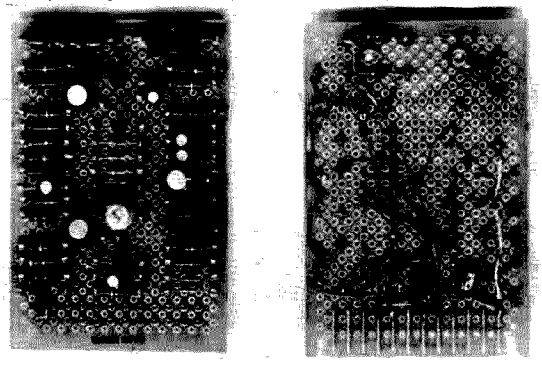


Fig. 7. Rear controls and connectors.

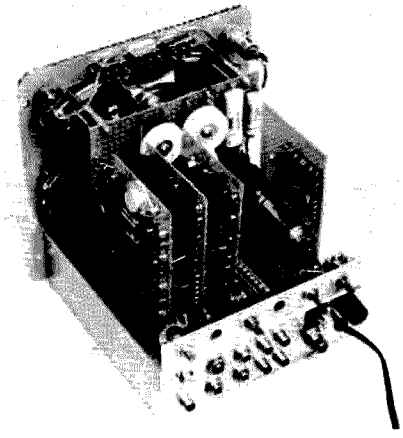
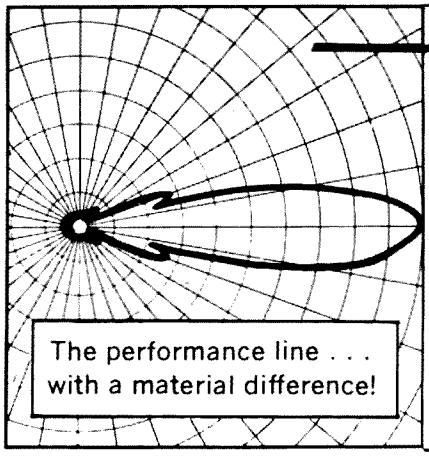
sprayed with two coats of black crackle, so that the speaker opening was "lost" in the overall black finish. The front panel is secured to the 7 x 7x 2 inch foundation chassis by the lower front control nuts.





Toroid coils and capacitors for the 2.1 khz low-pass speaker filter, together with transformers T1 and T2, are mounted on a piece of perforated phenolic measuring 5½ x 2¼ inches. This board is mounted by standoffs to the front panel through the speaker mounting holes. The 2 inch standoffs are assembled from two 1 inch spacers commonly used for expanding three-hole binders, and available from industrial stationery stores. The spacers have 8/32 studs at one end and 8/32 tapped holes at the other. Hole ends of the assembled standoffs are used to secure the speaker to the front panel with ¼" 8/32 flathead screws. Stud ends of the standoffs are used to mount the board with 8/32 nuts.

Rear mounted "preset" controls are mounted on a bracket fabricated from 1" aluminum angle stock, fastened to the top-rear of the chassis. Fig. 7 shows locations of all rear controls and connectors.

The plug-in boards used for the transistorized circuits and power supply are Vector type 837 WE, 4¼" x 3". These boards are equipped with twelve connector pins. The WE suffix denotes epoxy glass material. While they are also available in epoxy paper material (type 837), the slight extra cost of the glass material is considered well worthwhile, since it is impervious to heat, permitting stripping and reusing boards for new circuits. Flea clips are used for mounting the components to one side of the boards, while interconnections are wired on the opposite side, as shown in the photo.

ASBURY PARK, NEW JERSEY 07712, U.S.A.

Sockets are provided for six boards (sockets are Vector R612-1), with sufficient spacing to allow for component clearance. At present only four boards are utilized in my companion, leaving two vacant sockets for the addition of up to 50% more circuitry when the need arises.

Since a board-socket combination costs around $4.30, the budget-minded may want to make their own, which can be cut from suitable perforated stock sheet with .062 holes, and mounted to an appropriate male connector.

The sharp-eyed may note from the photos that two of the top-mounted panel slide switches are unwired. Well, together with the two unused Vector sockets, and the vacant control holes in the rear bracket, there is still room for expansion. And if additional front panel controls are required, with space getting at a premium, there are always those dual pots with concentric shafts, used in TV receivers.

Anyway, I think my companion will be around the shack for quite some time, even though it may pass through a continuing process of evolution.

A Simple Bench Power Supply

This power supply provides the choice of four popular output voltages, three current overload limits, and has an overload indicator, yet requires very few components. This principle of current overload protection can be easily adapted to existing power supplies. The size of heat sink required for a series regulator transistor can be reduced if this overload principle is used.

It soon became apparent after building a rather complicated bench power supply that this was not the end of my power supply requirements. This complex supply provided 0 to 20 volts at 500 ma maximum with full regulation and overload protection and is ideal for development projects. Unfortunately, when it is being used on the "latest" project it cannot also be used to supply other devices in use in the shack. It was apparent that a small supply with choice of fixed output voltages (3, 6, 9, or 12 volts) and moderate current capacity (200 ma) would fill the need. Overload protection was desirable to ensure that an unexpected overload or short-circuit could not harm either the supply itself or other equipment. The specification for this new supply therefore became:

Output voltage:	3, 6, 9, or 12 volts (switched)
Output current:	200 ma maximum
Internal impedance:	Less than 5 ohms, preferably about 1 ohm.
Ripple:	To be less than 10 mv peak-to-peak.
Overload protection:	To reduce the output voltage to a low level in the event of excessive load currents or short-circuits on the output terminals.

A further requirement that the transformer used should not be a "special" meant that one with a 6.3 volt secondary would

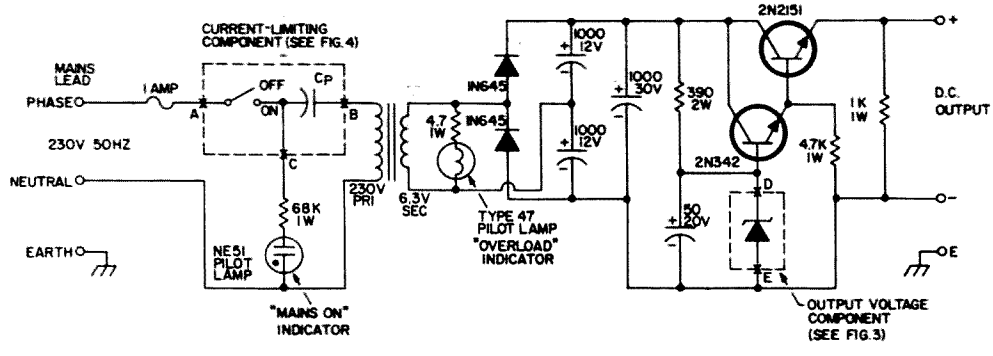

Fig. 1. Circuit diagram of the regulated power supply. The components in the dashed squares are simplified examples for purposes of explanation. A 230 volt supply is shown but the system can be easily adapted for 110 volts (see text). The "overload" indicator extinguishes when excessive output currents are drawn.

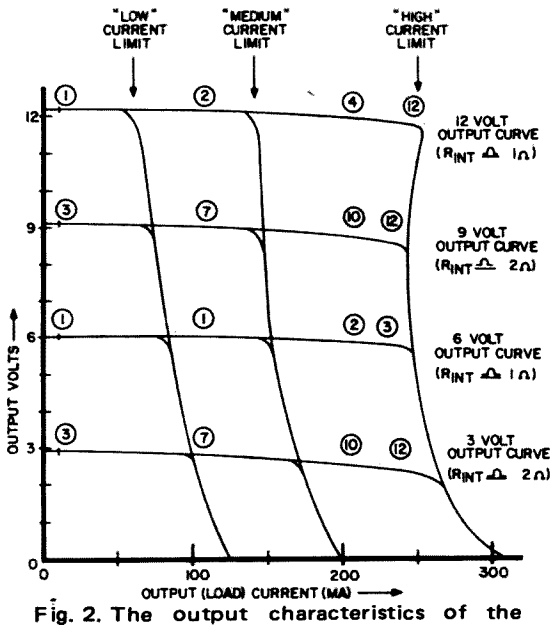

Fig. 2. The output characteristics of the power supply. Note that four output voltages (3, 6, 9 and 12 volts) and three current limits (at 50 to 100 ma, 130 ma, and 240 ma approx.) are available. The maximum currant limit may be increased (see text). The figures in circles represent peak-to-peak ripple voltages (in millivolts) at the load points shown, measured with an oscilloscope. Output impedance is about 2 ohms (at worst) on the flat part of the curves.

have to be used. This meant that some form of voltage doubler would be required to get a 12 volt output. This, however, represents a saving of two rectifier diodes over the four generally used in bridge circuits so in some ways is an advantage—provided the output ripple can be kept within the limits acceptable.

This, then, was the background to this project. The resulting circuit diagram is shown in Fig. 1 and the dc output characteristics shown in Fig. 2. Note that the input supply voltage is 230 volts at 50 hz. This is the domestic supply used in New Zealand and has been retained in this circuit in order to show the overload protection arrangements. Some component values will have to be changed when 110 volt primary transformers are used. As access to 110-volt 60 hz systems are just about impossible in ZL-land, details will be given later on the methods used to select component values for other systems of power distribution. It is hoped that some enterprising U.S. ham will investigate this with local components and write and tell this magazine about it, giving part numbers and component values.

The Circuit

The regulator circuit is basically a transistor series regulator with a zener diode as voltage reference. Two transistors are used in a compound circuit as cascaded emitter followers to ensure a low value of output impedance and to prevent any wide load variations from causing excessive changes to the zener diode operating conditions. A zener diode reference voltage is selected by means of switches to provide the output voltage required. The switching used is shown in Fig. 3. Two toggle or slide switches select the required zener reference diodes. Note that three diodes are used to provide four reference voltages.

The zener diode reference voltage has to be slightly greater than the resulting power supply output to allow for the base-emitter voltages of the two transistors. The transistors shown are NPN silicon types but many other types could be substituted, silicon or germanium. If PNP transistors are used, all diodes and all electrolytic capacitors will have to be reversed to provide voltages of the opposite polarity. If other transistors are substituted they should have as high a current gain as possible consistent with the current they are expected to handle.

I built the supply in an aluminum box 5 inches by 4 inches by 3 inches and the 2N2151 power transistor is bolted to the case but insulated from it by mica washers. A heat sink is not really required owing to the modest current output of this particular supply. More will be said about this later. Other constructional details will not be given

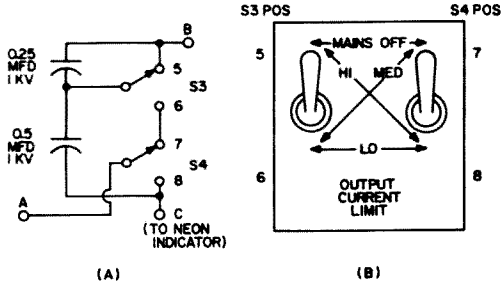

Fig. 3. The output voltage switching arrangements. Two SPDT switches select the required zener regulator diode. Switch positions in (a) are also shown in (b) which shows the panel labeling. Note that for 3 volts (as shown) the 3 volt zener is in parallel with a 6 volt zener—which of course will not be operating.

for there is nothing at all critical about the layout.

The 390 ohm resistor was selected to ensure that the zener diodes do not dissipate more than their 400 mw under any conditions. In fact they are considerably underrun. Other zener types could be substituted to provide other output voltages if required, but if this is done then some adjustment of the 390 ohm resistor may be necessary. The zeners may be individually selected if enough are available, to provide accurate output voltages.

The voltage doubler is conventional and again a wide range of diodes could have been used in place of the ones shown. A pilot light using a type 47 lamp is connected to the secondary of the transformer. A 4.7 ohm resistor is used to protect the lamp from the rise in secondary voltage on no-load, but this will be discussed later.

Overload Protection

The regulator system is capable of regulating the output against wide changes of input voltage from the main supply and it is this characteristic that is used in this unit to give overload protection. From the secondary of the transformer to the output, the regulator is of quite common design. Such a regulator will normally regulate up to the rated current limit of the series regulator transistor and other components, but will have little or no immunity against overload. Excessive load currents will generally cause overheating in the regulator with ultimate failure of one or several components. Many different techniques have been devised to protect this type of supply from overload. The most elaborate methods use some form of trigger circuit to electronically switch off the supply after a certain load current has been reached. This entails a reset procedure to restore the output after the cause of the overload has been removed. Another type of overload system ensures that the output voltage is abruptly reduced to a low and safe level after a certain load current has been reached. This type of protection is usually self-resetting in that once the cause of the overload has been removed, the supply will immediately return to its normal output voltage. It is one form of this type of protection that is used in this small power supply.

The simple addition of a capacitor in series with the transformer primary provides a convenient current overload protection with some other advantages. This capacitor is shown as Cp in **Fig. 1**. The effect is to cause the "vertical" voltage drop as shown on the characteristics in **Fig. 2**. It may seem at first to be a highly unlikely result so an outline of the action will soon be given. The high-current overload does double back as shown on **Fig. 2**.

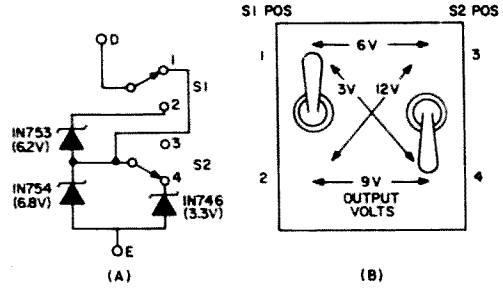

Fig. 4. The current-limiting switching arrangements. Two SPDT switches provide "off" and choice of three output current limits by selecting one of two capacitors, or both in series. The neon operates whenever the supply is "on," irrespective of which current limit range is in use. Switch positions are shown on both diagrams for ease of reference.

The switching arrangements for the current overload are shown in **Fig. 4**. Two SPDT toggle or slide switches (similar to the zener-switching ones) provide a "mains off" facility and the choice of three overload current limits. Two capacitors are used and these are connected individually and in series to provide a range of three capacitance values.

The Indicators

The neon pilot lamp is used to indicate that the supply is on. In one set of switch positions the neon is fed with 230 volts through the 0.5 μf capacitor. This capacitor has a reactance of 6400 ohms at 50 hz so has negligible effect when in series with the neon current-limiting resistance. This form of connection is necessary to ensure that the neon glows when the switches are in all three current-limiting positions, and yet is extinguished when the switches are in the "mains off" position.

It may seem strange that two pilot lights are necessary. The neon shows when the

power is on while the other lamp shows when an overload has occurred. The type 47 lamp extinguishes when an overload has been applied. While both lamps are lighted the supply is delivering its rated voltage. If the type 47 goes out then an overload has occurred. This arrangement works irrespective of the voltage output setting or the current overload range that is being used. With no voltmeters or ammeters used in the output (they were not considered necessary for the application in which this supply is used) this twin-lamp system has proved to be quite effective.

Overload Circuit Operation

The action of the series capacitor in the primary can be explained when it is realized that the input impedance of the primary of the transformer (when the dc output is on open-circuit) can be regarded in its simplest form as an inductance in series with a resistance. The inductance value is made up of transformer leakage reactance and some primary inductance while the resistance is made up of resistances representing the transformer losses and the load presented by the regulator components. The primary circuit is thus a series-tuned circuit, consisting of Cp, and the transformer inductance and resistance. This tuned circuit must not be at resonance at the mains frequency or excessive primary current would flow. The resonant frequency is made higher than the mains frequency and a change of Cp has the effect of changing this resonant frequency.

The primary current (with no load on the output terminals) is increased considerably with the inclusion of Cp. The current flowing is not in phase with the supply voltage so the power dissipated in the primary is small. The voltage across the transformer primary is increased to about 300 volts when the 0.5 μf capacitor is in circuit. This in turn means that the output of the voltage doubler is increased to about 20 volts dc when the supply is on "no load." The series transistor regulator accepts this 20 volt input and reduces it to 12, 9, 6 or 3 volts at the dc output terminals, even on no-load. When a load is connected to the regulator dc output terminals it has the effect of changing both the inductance and resistance values seen at the transformer primary. The resistance value increases as the load increases while the inductance value decreases. The resonant frequency of the primary tuned circuit therefore rises and the impedance presented to the mains input increases, causing a decrease in primary current. The Q of this series tuned circuit thus falls. The output of the voltage doubler and the 20 volt dc level at the input to the regulator drops. At some value of load current this dc voltage will have dropped to a point where the regulator can no longer operate satisfactorily and the output dc voltage now takes a downward plunge. The exact mechanism causing this steep fall is rather complex for the current and voltage waveforms at the transformer primary become distorted even though core saturation has not been reached.

At the overload point at the top of the downward plunge of the voltage curve, the type 47 pilot lamp goes out, showing that the transformer secondary voltage has dropped to a low level. With an overload current at the dc output terminals, the voltage at the output of the voltage doubler has dropped to about the same voltage as that at the dc output terminals, and with a short circuit, it drops to zero volts.

The overall result is most effective and especially is this so when component economy is considered.

The voltage rating of the capacitors must be high because under no-load conditions the voltage across the capacitor rises to about twice the mains voltage. The voltage rating should be 1 kv for 230 volt systems and 500 volts for 110 volt systems to be sure that the component will not fail.

Determining Component Values

This current-limiting technique has been applied to another power supply and it was found that a 4 μf series capacitor (1kv oil-filled) produced as steep a falloff as the 0.5 μf on the supply described. The value of capacitor to use for a particular value of current limiting is just about impossible to calculate for little is usually known about the transformer input impedance for the resulting dc load. The capacitor value is best determined experimentally by substituting

value after value (starting off with a 0.1 μf for 230 volt systems and a 0.25 μf for 110 volt systems) and plotting the output characteristics using an ammeter, voltmeter, and adjustable load resistor of suitable value. Increase the capacitor values in say, 0.25 μf steps until the desired cutoff current is reached.

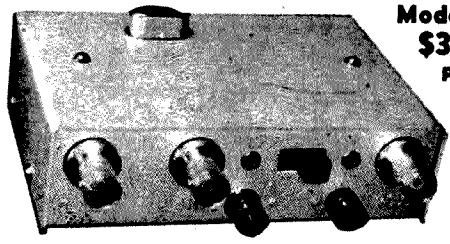
One point must not be overlooked. If you try this with an existing supply (as I hope you will) make sure that the voltage ratings of any filter capacitors are not exceeded. Remember that the dc voltage output of the rectifier is increased by approximately 50% when the supply is on no-load. The primary voltage is increased by a like amount, but this is not as serious as it appears to be for the power factor is far from unity and little increase in transformer operating temperature (if any) will result. An ac voltmeter across the primary can be used to keep this under observation while substituting capacitor values. Remember that excessive primary currents can be drawn if the primary approaches resonance, so start off with the values of capacity quoted and increase it in small increments until the desired limit is reached, keeping an eye on filter capacitor voltage ratings. Remember too that you are playing with mains power so play it safe.

Other Advantages

Two other unexpected benefits also accrue from this series capacitor current-limiting arrangement. When first switching on, all the filter capacitors are discharged and the diodes would normally pass a very high current during charging. With this series capacitor in circuit, this charging current appears as an overload current and the initial charging current is limited. A resistor in series with the transformer secondary to limit the switch-on charging current as often used is now not necessary. The second added advantage concerns the size of the power transistor heat sink (if used). Because the dc input voltage to the regulator falls as the load current increases, the power dissipated in the series regulator is not as high as would normally be expected, and large dc output currents can be handled before a heat sink becomes necessary—this alone is an economy in space.

A change in mains frequency will have the effect of changing the current-limit level but this is unlikely to be bothersome if you draw your power from a large distribution system. A change of input mains voltage has a very small effect on the limit level and can be overlooked.

Ripple voltages, measured with a Tektronix 545B oscilloscope are shown in circles on Fig. 2 (millivolt peak-to-peak values), at various load levels. The lower output impedance and inferior ripple of the 3 volt and 9 volt curves can be attributed to the use of the 3 volt zener with its high dynamic impedance.



This supply has met my requirement quite satisfactorily and is giving good service.

Acknowledgment

I wish to thank Louis W5KFV for providing many of the components used in the development of this and many other projects.

THE BEST
2 METER
CONVERTER

Model 407
$34.95
ppd.

144-146 MHz in. 28-30 MHz out
or 146-148 MHz with a second crystal

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of hundreds of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced? Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait? Then send us a postal money order for $34.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

Slow Scan Color Transmission

Introduction

In 1861, James C. Maxwell demonstrated the principles of three-color photography. Maxwell analyzed a landscape scene through red, green and blue filters, and from the black and white negatives so produced, made three positive lantern slides. Then, by projecting the black and white lantern slides back through red, green, and blue filters, and superimposing the three pictures, he produced a color picture of the landscape. The principles of tricolor analysis and synthesis first demonstrated by Maxwell are still used today in the field of color photography, color printing, and color television. For example, the first close-up color photographs of the moon's surface were produced by a Surveyor satellite suitably equipped with a black and white television camera and color separation filters. More recently, the color photographs of the earth taken by an Application Technology Satellite (*Scientific American,* 1969) are but another example of color photography by means of color analysis and synthesis.

The application of color analysis and synthesis techniques to amateur television follows as a logical step in the development of this communication mode. In particular, the technique is here applied to the field of slow-scan television, giving the amateur a capability for the long-distance transmission of color information.

Color Principles

In 1801, Thomas Young put forth a hypothesis that human color vision is based on a three-part color analysis, in the eye, of the light received from an object. Young's investigations were extended by Helmholz and others, who showed through mixing experiments that almost all colors could be matched by a mixture of three colors. The three colors used in the matching process are not specified; but then, there are no three unique components that must be used for color matching. It can be shown, however, that red, green, and blue components permit matching the greatest spectral range of colors (without using negative quantities of a component), and for this reason, red, green, and blue are considered as the *primary colors.*

James C. Maxwell, in 1861, demonstrated that the above principles could be used to reproduce a colored scene, and thus laid the foundation for current three-color photography, printing, and television. Maxwell exposed three separate photographic plates to a landscape scene through red, green, and

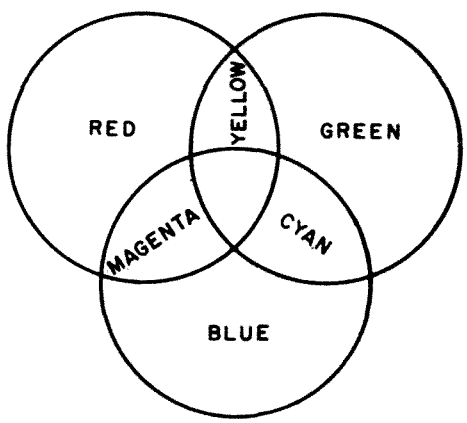

Fig. 1. Color mixture by addition.

blue glass (filters). The photographic emulsion exposed behind the red filter, when developed, showed, in terms of silver densities, the amount of red light reflected from the scene. Areas of the landscape which reflected greater amounts of red light yielded greater densities on the corresponding parts of the black and white negative. Where a lesser amount of red light was reflected, a lesser density was obtained. Similar statements apply to the negatives made with the green and blue filters (substitute "green" and "blue" for the word "red" in the above sentences). Colors formed from two or more colors were recorded on two or more negatives in proportion to the amount of each primary color reflected. Thus, the set of three black and white *separation negatives* recorded the *tricolor analysis* of the scene.

To reproduce the landscape analyzed by tricolor analysis, Maxwell first produced a positive transparency from each of the three separation negatives. These positives were then placed in magic lanterns, and a colored filter corresponding to a given positive's separation filter was placed in front of each lantern. That is, a red filter was placed in front of the lantern containing the positive made from the "red" negative, etc. With the intensities of the lanterns properly adjusted, a reproduction, or synthesis, of the landscape appeared on the screen. Although the reproduction was poor by today's standards, the basic principles of three-color photography had been established.

Maxwell reproduced his image by *additive color synthesis,* wherein three colored light images are added together to obtain a suitable mixture. This process is illustrated in Fig. 1, where white-light sources are projected onto a screen through three primary color filters. Besides the areas where the primary colors are observed, and where all three colors are superimposed (white), three additional colors are observed. These are: cyan, (white light minus red); magenta (white light minus green); and yellow (white light minus blue). This suggests that color mixing may be performed using the colors of cyan, magenta, and yellow; that is, by subtractive mixing.

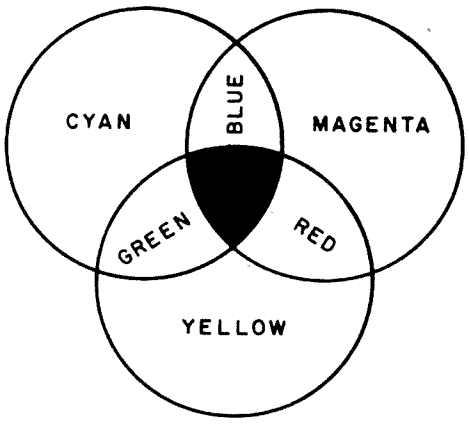

Fig. 2. Color mixture by subtraction.

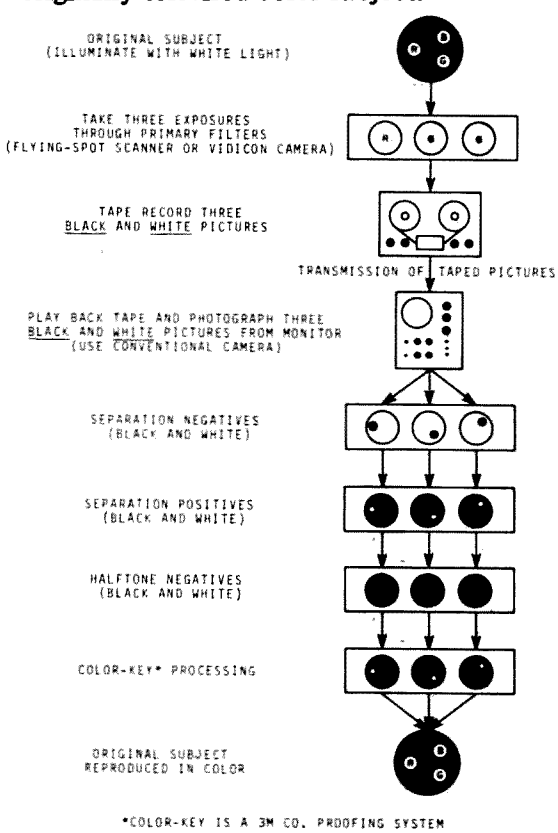
Fig. 2 shows a subtractive mixture of colors produced by projecting a single white light source through an overlapping set of staggered subtractive filters (i. e., cyan, magenta, and yellow filters). Besides the three subtractive colors observed on the screen, we can see areas of red, green, and blue. Where all three subtractive filters overlap, no light (black) is projected. Thus in Maxwell's experiment, let us dye the positive silver image prepared from the red filter separation negative cyan. Similarly let us dye the positives prepared from the green and blue filter-separation negatives magenta and yellow, respectively. If we now place all three dyed transparencies in the same projector, we obtain a color picture (without having to use any filters in front of the white light projector) by *subtractive color synthesis.* Our present color photography and color printing methods employ the principles of subtractive color synthesis, and it is this technique we used to synthesize the first color picture transmitted by slow-scan television.

Method

The general method employed to analyze and synthesize the slow-scan color television picture is shown diagrammatically in Fig. 3. The subject here, a black circle containing red (R), green (G), and blue (B) circles, is first illuminated with white light. The subject is then viewed (in sequence) through red, green, and blue filters by an SSTV flying-spot scanner or vidicon camera, and the three black and white pictures obtained – which might be called the separation pictures – are recorded on a conventional audio tape recorder. Once taped, the pictures may be transmitted over the air or

on the telephone lines; the tape can also be forwarded through the mail. Whatever the means of transmission, the pictures are eventually played back at the receiving end, whereupon three black and white photographs, corresponding to the three separation pictures, are taken of the monitor's display. Note that no filters are required at the receiving station; the three black and white pictures transmitted already contain the necessary tricolor separation information.

Once the monitor's output has been photographed using a conventional camera (time exposures are taken of the three separation pictues), the film is developed. This yields a set of separation negatives from which are prepared three positive prints. Halftone negatives are now made from the three positives, and these negatives processed using the Color-Key printing technique. If the three processed Color-Key films are now superimposed on a white background, the resulting color image is a reproduction of the originally televised color subject.



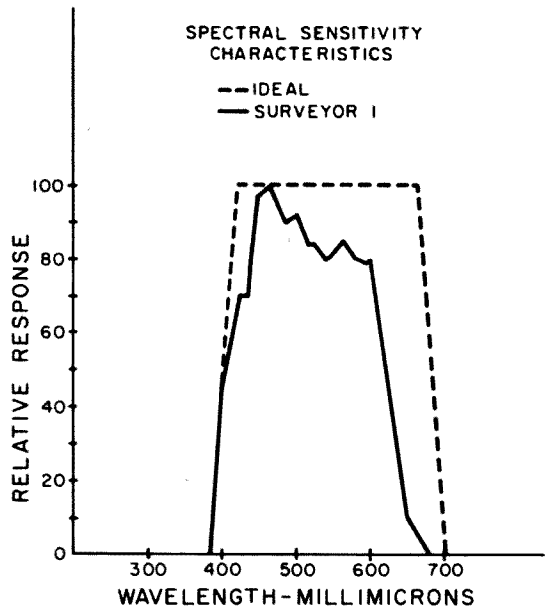


Fig. 3. Color reproduction by means of color analysis and synthesis. This was the method used by W4UMF and Mr. Tarr to reproduce the first color picture transmitted by amateur SSTV.

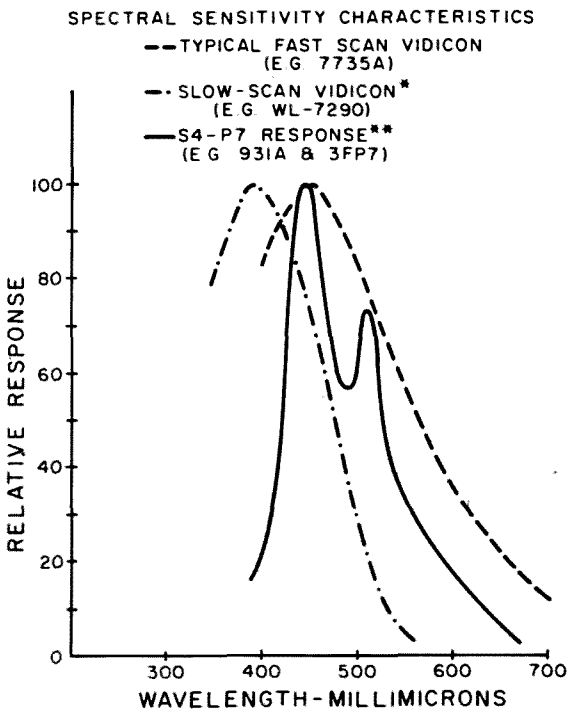
MODIFIED AFTER: SURVEYOR I: PRELIMINARY RESULTS, SURVEYOR SCIENTIFIC AND EVALUATION AND ANALYSIS TEAM, SCIENCE, VOL 152, 24 JUNE 1966

Fig. 4. The ideal total-system response for color analysis work. This response is shaped, using single-color filters, to produce a response which matches the standard color-matching functions. The total-system response for the camera aboard Surveyor 1 is shown for comparison.



Having outlined the basic principles of color analysis and synthesis, and the application of these principles to the transmission of color pictues by slow-scan television, let us now turn in detail to the techniques employed.

Color Analysis

Ideally, one would wish that the response of his television system be similar to that shown by the dashed line in Fig. 4. The response is seen to be flat over the entire visible spectrum, and thus, it should be possible to select single-color filters which, when placed in front of the imaging system, produce an overall camera-filter response which can match the standard color-matching functions (Commission Internationale de l'Eclairage, 1931). That total system response functions close to the ideal can be achieved is evidenced by the spectral response curve of the Surveyor 1 television cameras (clear position on the filter wheel, solid line, Fig. 4). Overall camera-filter spectral response functions for Surveyor 1 can be found in the report of the Surveyor

Scientific Evaluation and Analysis Team (1966), and for Surveyor 3 in Shoemaker, et al. (1968).

As television cameras with "ideal" spectral response curves (like those of the Surveyor cameras) are necessarily expensive, we should not be surprised that the imaging systems employed by amateurs use tubes with response curves far from the ideal. Fig. 5 shows the response curves for three classes of imaging systems used in amateur slow-scan television work. Flying-spot scanners (e. g., see Hutton, 1967) typically use 931A photomultiplier tubes (S4 response) together with a P4 or P7 CRT raster source. Slow-scan vidicon cameras, on the other hand, generally employ image tubes like the Westinghouse WL-7290. Only recently, Taggart (1968) and Hutton (1969) have demonstrated the use of conventional fast-scan vidicons (e. g., 6326, 7038, 7735A, etc.) in the slow-scan mode. Thus, we essentially have three classes of image-tube response to choose between. Of these, the conventional vidicon's response is superior, followed by the spectral response of the S4-P7 flying-spot scanning system. The slow-scan vidicon, however, peaks in the violet, and experiments at W4UMF have shown that its extremely low output in the red (visible wavelengths greater than 610 millimicrons) eliminates it as a possible image pick-up device for direct color separation work.

*REF.: SLOW-SCAN VIDICONS; LIGHT INTEGRATION & STORAGE, NARROW-BAND VIDEO TRANSMISSION, WESTINGHOUSE, APRIL, 1968.

**REF.: AVERAGE RESPONSE; S4 SENSITIVITY (2870° K TUNGSTEN SOURCE) TIMES AVERAGE P7 SPECTRAL-EMISSION CHARACTERISTIC, RCA HB-3 TUBE MANUAL.

Fig. 5. Three classes of image-tube response used in amateur SSTV systems. The response of a conventional vidicon is preferred for color analysis work, followed by the response for an S4-P7 flying-spot scanning system.

Robert Tschannen's (W9LU0) dual-931A flying-spot scanner was used for the color analysis phase. This scanner, similar to that described by Hutton (1967), employs a 15 hz horizontal frequency and an 8-second frame period (120 lines). The total-system spectrum response function was shaped for color separation by inserting red (Wratten No. 25) and blue (Wratten No. 47) filters in front of the photomultiplier tubes. No filters were used in producing the green separation picture. While the green separation picture therefore contained, in reality, blue-green information, this color bias was compensated for in the production of the Color-Key print.

The subject chosen for the initial color separation tests is shown on the cover, bottom left. Anyone who has ever tuned a color TV set or viewed a color slide can attest to the fact that the faithful reproduction of skin tones is essential to good color imaging. Thus, it was felt that a subject such as that chosen would provide a good test of the techniques to be employed.

To correct for the non-uniform spectral response of the system, the following procedure was used in preparing each of the separation pictures. With a given set of color filters in place (or no filters, in the case of the green picture), a white card was substituted for the subject picture, and the phototube outputs set to a predetermined level. This level, which was the same for all three white-card separation pictures, was sufficiently high to produce a white picture on the slow-scan monitor. Following equalization of phototube outputs, the subject picture was placed in the scanner, and 8 separation-picture frames were recorded on

magnetic tape. Every effort was made to replace the subject picture in the same position following each equalization adjustment; an attempt was also made to maintain a common size for the scanning raster. The necessity of alternately changing picture and card for primary output adjustment could account for some of the misregistration seen in the synthesized picture. It is to be noted that slight defocusing did occur on the red separation picture. This is a result of having to drive the raster source CRT quite hard before obtaining the desired output equivalence.

The recorded pictures were mailed to W4UMF for color processing. The question of whether these pictures should have been transmitted by SSB on 20 meters, via the phone lines, or by tape through the mail is purely academic; tests conducted during the past two years have proven all three transmission modes capable of yielding high-quality SSTV pictures.

Color Synthesis

To produce the required separation negatives, the taped separation pictures were played back through a 3" monitor, and photographed on black and white 35mm film. The camera used was a Bell and Howell-Canon single-lens reflex with a 35mm f/1.8 lens. A close-up lens was also attached. The camera was tripod mounted, and a remote shutter trigger employed to minimize changes in the camera's position. While small lateral and vertical changes in the camera's position can be corrected for in printing the Color-Key picture, changes in the distance between the camera and monitor will produce variations in picture magnification. Such variations in image size are difficult to compensate for, and can result in significant color fringing.

Use of 35mm film necessarily required that the separation negatives be enlarged prior to printing. This suggested that fine-grain film be employed. The film chosen was Kodak Panatomic-X.

The Panatomic-X film has an ASA rating of 32. Because of this rating, and the low light level of the CRT flying spot, it was necessary to experiment with aperture settings. Aperture settings of 1.8, 2.8, 4 and 5.6 were used in obtaining the 3-picture sets.* All pictures taken were 8-second (one frame) time exposures. The black background of the original subject was used as a guide for proper adjustment of the monitor. That is, the brightness for each picture was set such that the CRT beam was just extinguished in the black portion of each frame.

The exposed film was processed in accordance with the film manufacturer's specifications. This not only assured us of obtaining proper silver densities in the negatives, but should also permit duplication of the results obtained to within narrow limits.

The 35mm separation negatives photographed from the monitor were quite contrasty. This was due in large part to the lack of tonal gradation in the pictures displayed on the monitor. As the P7 cathode-ray tube is capable of reproducing only 4 or 5 shades of gray, some tonal adjustments had to be made in the synthesis process. These adjustments will be discussed in detail later in this section.

From the 3-picture sets available, separation negatives were chosen for Color-Key processing. The choice of negatives was not too critical, as one can exert some control over picture characteristics (i. e. density, contrast, etc.) in a separable subtractive color process such as the dye transfer or Color-Key process. The white flaring was introduced in the analysis process (glare).

The Color-Key method for color printing was used to synthesize the tricolor-analyzed picture. For a complete survey of Color-Key printing the interested reader is referred to the literature on color printing processes.

Color-Key is primarily used by lithographers to produce proofs of separated negatives for multicolor printing. The process can be used by anyone with access to a high intensity lamp. In addition, materials are available in most areas of the country, which is not true of other processing mate-

*The monitor at W4UMF employs a 3RP7A CRT, with an accelerating voltage of 1600 volts. Most monitors use 3FP7A, or 5ABP7 CRT's, which generally employ accelerating voltages closer to 3100 volts. If tubes of the latter type are employed, and Panatomic-X film is used, it is suggested that stops between 2.8 and 8 be tried. If a film such as Plus-X is used with a high accelerating voltage CRT (~3100 volts), f/stops between 8 and 11 should produce good 8-second time exposures.

rials investigated (e. g., dye tranfer materials). Color-Key is easily handled in subdued light and has a one-step developer which is applied with a cotton swab.

Because of its lack of tonal range, Color-Key must be exposed using a halftone or screened negative.

The Color-Key process uses three sheets of film, each dyed one of three colors: cyan, magenta, and yellow. The halftone negative for the complement of each Color-Key dye is exposed and developed separately. The resulting Color-Key positives are then aligned, one on top of the other. Viewing through the composite film *should* produce a color reproduction of the original color scene. We use the word "should" because of the problems encountered.

It was mentioned earlier that the negatives photographed from the monitor were of high contrast. As such, the glossy photographs were also without tone gradation, and thus, the halftone negatives had relatively little tone variation. The reason for this follows. Let us examine the synthesis process in detail. Consider that black and white picture on the monitor which had been analyzed through the red filter. The picture had white areas on the screen where the skin tone was on the original. As the skin tone (large percentage of yellow-red) would pass through a red filter, the face should have appeared light gray. The green area of the dress, composed of cyan and yellow, was not entirely passed by the red filter, and should have appeared dark gray on the screen. This area however, was displayed as black. This shift to higher contrast is a product of the monitor's CRT limited dynamic range. Thus, it was not possible to accurately reproduce the tones of the original picture. Similar statements apply to the green and blue separation pictures as observed on the monitor. As such, we were required to use some color correction to reproduce the tone values between white and black.

After all the Color-Key positives were made, it was determined that more magenta and yellow was needed to reproduce a realistic skin tone. Adding these colors would also make needed corrections in other areas of the picture to correct for the blue-green bias in the original SSTV separation piotures. Color-Key sheets containing dot patterns of 50% color value at 85 lines per inch were added. This corrected the color to within reasonable limits over the entire picture. No attempt was made to correct particular areas of the print; all areas were treated uniformly.

Results

The processed color print is shown on the cover, at the right. In judging the quality of the reproduction, we should be aware of the inherent resolution limitation (120 lines) of the slow-scan system, and the limited dynamic range of the monitor's CRT. To the extent that the Color-Key print approximates the color of the subject, however, we class the quality of the synthesized color print "fair."

Comments and Conclusions

In the case of the picture processed above, the original color photograph was available to be used as a guide in the synthesizing process. To eliminate the need for viewing the original color photograph during color synthesis, it is suggested that a small color-bar set be included in pictures to be analyzed. Upon synthesis, accurate reproduction of the color bars will insure proper color balance in the subject.

We have demonstrated the feasibility of transmitting color pictures by slow-scan television, using the method of color analysis and synthesis. In particular, picture reconstruction was performed using a separable subtractive color process – the Color-Key process. Though the color analysis phase of the test and the production of the separation negatives may seem heuristic in character to the critical experimentalist, the procedures described nevertheless do work. We would hope that more experimentation will be done using the Color-Key process as this process can produce excellent results given separation negatives of good tonal gradation.

That prints made using the Color-Key process are considerably more expensive than conventional color prints, and that an experienced amateur photographer is more apt to obtain the desired results when using this process, would seem to limit the application and use of the color transmission method described. However, given today's

technology in quick-processing films (e. g., Polaroid Polacolor), and a continued experimental effort on the part of the amateur-photographer, it is expected that technically and economically more appealing synthesis techniques will be developed shortly for the color transmission by slow-scan television.

Fascinating Fundamentals

Volta and His Pile

Although this article is about Volta and the invention of the electric cell, it would be incomplete without at least a mention of another Italian, Luigi Galvani. Both these men stumbled over the same principle, and both men misinterpreted it, although Volta's interpretation was most nearly accurate. Galvani's main field of operation was electric detectors. After his wife was scared out of her wits by a pair of frog's legs that jumped without having the rest of the frog attached, and after she suggested to her husband that the phenomenon just might have something to do with his electric machines, Galvani "discovered" this very sensitive method of electric detection.

Galvani worked for a number of years with his frog legs, and during the course of his experimenting, he completed a circuit to a pair of legs by way of a copper wire and an iron fence. He observed that the legs would jump when connected through two different metals, but not when only one kind of metal was involved. Not being concerned with electric generation, he continued his experiments in the field of detection.

This was in the latter part of the eighteenth century, and in those days, the only source of electric power was from electrostatic machines. Just a few decades before, Franklin had discovered atmospheric electricity through his famous kite, but this had proven to be a difficult source to control. Nobody had, as yet, said so, but the thing most needed to further the progress of electricity was a source of continuous current.

Galvani had been convinced that his connection of the frog legs to the metal strips had shown evidence of what he called "Animal Electricity." Volta thought differently. He felt sure that the source was not in the animal tissues, but rather in the connection between the two metals. He came awfully close. For quite a while he experimented with a great many combinations of metals, and eventually came up with a list so arranged that any metal shown would generate a positive charge when contacted with any metal below it. His one misconception, and it was a minor one, was that it was the CONTACT between the two pieces that produced the charge.

Volta had tried to improve the connection between the metals by moistening them with brine. In time he found that the same result could be had if the two pieces were altogether separated. He still believed, however, that it was only the connection between the metals, and not a reaction with the brine that produced electricity. Soon he was making stacks of his cells piled one on top of the other. This, naturally, produced a more powerful charge and, while its power was nowhere near that of the static machines, it never had to be recharged. Here,

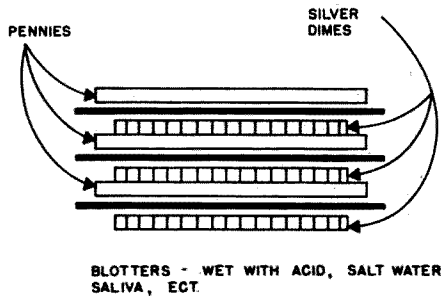

Fig. 1. Volta's pile (also called the spit-on-a-dime battery). Blotters should be moistened. This always used to be made with the older silver dimes. I don't know how well it will work with the new ones.

then, was a source of continuous current. Volta published his conclusions in a letter which was read to the Royal Society in England on June 26, 1800. On that day, electricity took a giant step forward. In the next half century, many improved cells were developed by such men as Faraday and Davy, but it was Volta who started it.

Volta's one misconception, that electricity was being generated by the action of the two metals with each other, was not too far off. Actually, it is the action of the two metals AND A CHEMICAL. In the table, we see the potentials which can be produced with a few common metals and various solutions. To determine the potential you will get, take the DIFFERENCE between the potentials of the two metals you will use. For instance, with a sulfuric acid solution, zinc has a potential of 0.0, and copper, 1.007. If you immerse a strip of copper and a strip of zinc in a jar of sulfuric acid, there will be a potential of 1.007 volts between them. Lead, however, has a potential of 0.513. A cell made of copper and lead will produce only 1.007-0.513, or 0.494 volt. Try it yourself. All you need is a peanut butter jar (empty), some metal, and some acid. You can get the acid at any gas station. Just ask for some battery acid.

Solution	Sulphuric Acid	Lye	Salt
Metal			
Zinc	0.0	-0.321	?
Lead	0.513	0.318	0.512
Tin	0.513	0.002	0.503
Copper	1.007	0.802	0.809
Silver	1.213	0.958	1.013

Table 1. When immersed in any of the solutions shown, any two of these metals will produce a voltage equal to the difference of their potentials. For instance, Zinc and Silver in a solution of lye: E = 0.958 (-0.321), or 1.179 volts.

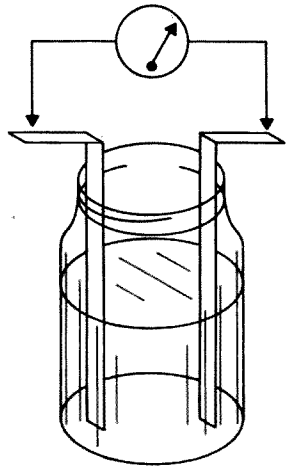

Fig. 2. A simple jar cell. See table for solution and metals.

I once made a demonstration cell by filling a tin can with a solution of vinegar and immersing a copper pipe. Between the copper and the tin, there was about half a volt, and if I had used sulfuric acid instead of the vinegar, that would agree quite well with the table.

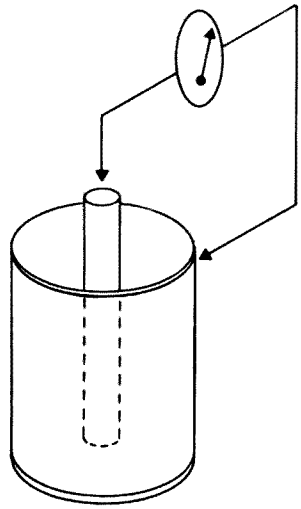

Fig. 3. The "can-full-of-vinegar" cell.

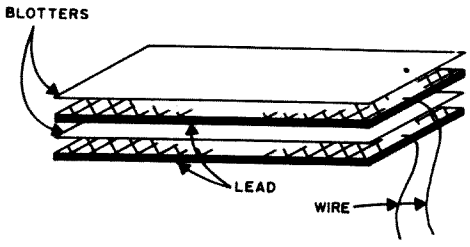
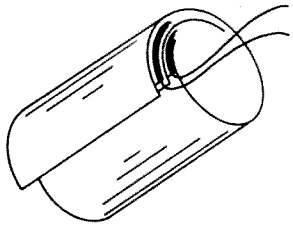
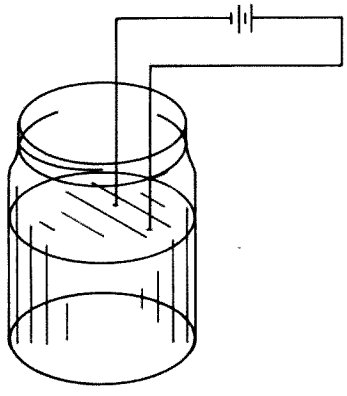


A storage battery is one in which the chemicals can be renewed by sending a current through it in the reverse direction. Take two strips of lead, and score criss-cross lines on them with a scriber. Then roll them together between two pieces of blotter,

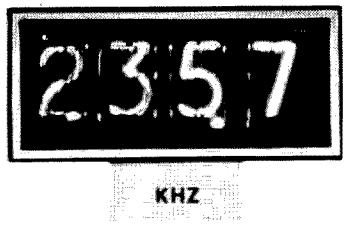


making sure that they do not touch each other. Put the whole thing into a jar and add some battery acid. Now "charge" it by connecting it to a two or three volt dc source. After an hour or so, remove the source and you will find you have made a 2 volt storage cell.

. . . W2FEZ ■



Score the lead like this.



Roll them up.

Put them in a jar and charge them.

Fig. 4. A simple storage cell. Make sure the lead pieces do not touch each other. Fill the jar with battery acid obtained from a local gas station. Once it has been charged the first time, mark the polarity and always observe it in future chargings.

SIGNAL/ONE'S CX7 GIVES YOU

Electronic counters belong in the laboratory . . . because they're big, expensive, precision instruments . . . right? So what's one doing in the CX7? Well, it gives you . . . . . .

- CALIBRATION ACCURACY OF 100 HZ at every point in every band
- READOUT DIRECT TO 100 HZ . . . without interpolation
- LIFETIME PRECISION . . . free of error due to aging or environment
- BIG, BRIGHT DISPLAY . . . virtually impossible to mis-read

SIGNAL/ONE engineers did it by putting state-of-the-art technology to work in a precision counter no larger than a small book. This remarkable unit actually counts each individual cycle of VFO output during a precise (crystal-controlled) 1/100 second time interval . . . and displays the last four digits of the total on an electronic readout. (For example, a VFO frequency of 3521.7 kHz (3,521,700 cycles/second) yields a 1/100 second count of 35,217 . . . and the display shows 521.7 kHz). The readout is as accurate as the 1/100 second timing. Timing is derived digitally from the 100 kHz reference standard. So, by simply zero-beating the 100 kHz oscilator to WWV (or a BC station) you automatically calibrate the VFO to 100 Hz accuracy . . everywhere.

Wayne Green

Dear Wayne,

Since I have enjoyed reading the material you have written over the years, I have made up a little antenna story for you. I hope you enjoy reading it.

If by chance it has publication value, there is an automatic discount for rewriting of 27%.

The commercial price is therefore your choice of 73¢, $7.30, $73.00, or $730.00. I positively will not accept more.

James M. Fisher, W3KNG

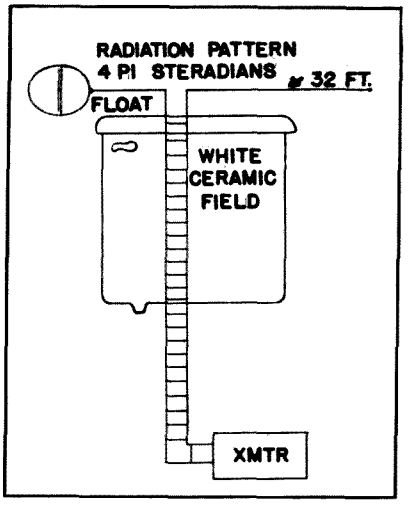
The 20 Meter DX Copper Ball Antenna

On a recent trip through a large hardware store, it was discovered that there is a plastic toilet float on the market. This may mean the eventual demise of the classic copper toilet float. In case this could happen, it was thought advisable to describe the old "toilet ball" 20m DX antenna before parts for this famous old antenna are no longer available.

The origins of this trusty old skywire, if documented, are not available to this author. Like legends, the design has filtered down through word of mouth. However, a tip of the hat to the inventor, wherever he may be. It's a good one.

It was developed when 20m first became a ham band, long before the beams of today were in use. Basically, it is a very simple antenna to build and use, and will perform as well as any dipole. The components themselves are inexpensive, and no elaborate towers or rotators are required. It has no apparent directive pattern. Using this antenna on 20m CW, and the modest power developed by modern transceivers, barefoot, it is easy to work around the world.



The theory behind the design is very simple: Half the transmitted energy is concentrated on the outside of a copper toilet float, and half is loaded into a 32 ft. wire counterpoise. The ball develops a fierce concentration of an electrostatic field, and really shoots this energy out, covering the entire world (which, incidentally, is also globe-shaped).

The counterpoise, loaded primarily with the electromagnetic component of the transmitter's output, nicely provides background fill for the ball's radiation, giving depth and smoothness to the signal. The ladder line feed not only separates the electrostatic and electromagnetic fields to their ball and counterpoise, but actually convert the low impedance energy in the coaxial cable to the hot juice needed to make the ball sizzle.

Construction is not difficult. The insulators around the ball mount should be ceramic, and if you are going to use a kW, they should be a minimum of 4 in. long. The counterpoise should run in fairly clear space, several feet from trees or buildings, if possible. The ladder line should be mounted by regular TV standoffs, except for the top three feet, which should be either in the clear or on good white ceramic. The entire ladder should be guarded from contact by children or pets.

The whole shebang, ball and counterpoise, should be about 16 ft above ground. Build it and have a BALL!

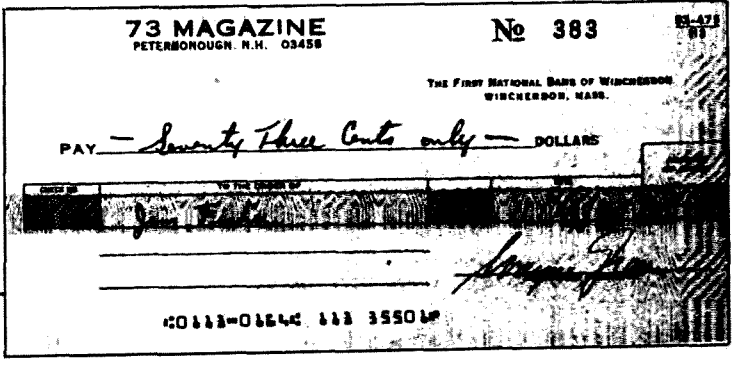
73 MAGAZINE
PETERBOROUGH, NEW HAMPSHIRE 03458

Dear Jim,

Thanks for letting us have the first opportunity to publish the article on the copper ball antenna. Some of the 73 staff became so inspired by your write-up that they built up a couple of the devices for the station here.



Needless to tell you, we've had phenomenal success with DX, even to the extent of working contacts in areas thus far uncharted.

Some inconvenience has occurred as a result, however. The nearest service station is several miles away, and its restrooms are damp and cold. Hardly a substitute for the nice ones we had on the premises before your article came in.

At any rate, we accept your article, and tender our check to you herewith.

73,

Wayne Green

Base - Tuned Center - Loaded Antenna

No, the title is not incorrect. An antenna can be center-loaded without having the reactive element physically present at the center of the antenna. Transmission line transfer of the reactive element is the key.

There is certainly nothing new about base inductive loading of a vertical antenna. The method is convenient and often allows easy construction of an antenna. The disadvantage, of course, is low efficiency when the antenna is shorter than ¼λ long at the operating frequency. As shown in **Fig. 1**, the high current flow at the base of the antenna means that the greatest current flow takes place through the coil's relatively small conductor. Various solutions have been tried to get around the problem of distributing the current flow in an antenna such that the reactive elements necessary to bring the antenna system into resonance do not also produce the greatest losses. The helical antenna was one solution. By distributing the inductive loading along essentially the entire length of the antenna, the average current flowing through the base section of the antenna was reduced. Center lumped inductive loading (**Fig. 1**) has become the most popular method, however, since it allows the heavy base current to flow through the bottom section of the antenna, which is not loaded, and because of its constructional advantages, particularly for mobile antennas.

The method is not always practical for fixed station situations, however, where the antenna center may not be accessible to change coils for various bands. Usually, the fixed station operator who is constrained to using a vertical antenna on several bands has had to settle for base loading and could simply take the approach of making the base loading inductor as hefty as possible in an effort to reduce its losses. This article explores a method by which the efficiency of such an antenna can often be considerably improved by a form of pseudo-center loading using a transmission line to transfer the reactance of a loading element located physically at the base of the antenna electrically to its center.

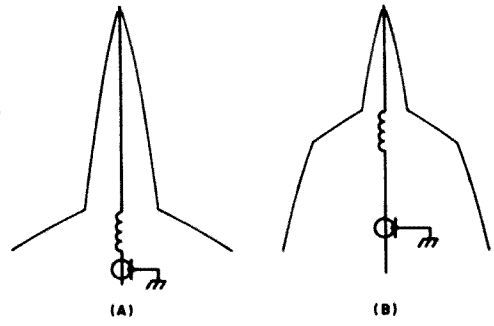

Fig. 1. Improved current distribution of center-loaded antenna (B) over base-loaded antenna (A) allows highest currents to flow where ohmic losses are low.

A note should first be made concerning the function of the loading inductor in a center loaded antenna. The inductive reactance is necessary to make the electrical length of the antenna equal a ¼λ so that the base impedance will match a coaxial transmission line and the antenna will accept a transfer of power from the transmission line. Unless the loading inductor is extremely long or wide, it does not radiate any

appreciable signal. The radiating is done by the rest of the antenna. If the copper losses in the inductor are not kept low, the inductor will act in a manner similar to a dummy load and simply produce heat. The inductors used for the center loading of short mobile antennas are usually not shielded because weather protection can be obtained by epoxy coatings and a shield must reduce the inductor's Q or efficiency. The coil, however, could be shielded with a large enough enclosure so that the effect upon the Q would be small and antenna performance would not be affected thereby.

So, if the antenna saw the proper value of loading inductance at its center, regardless of where the physical inductor was placed, it would operate the same as it did with the physical loading inductor at its center.

Reactance Transfer

One method that can be used to transfer a remotely located reactance to the center of an antenna is via a transmission line. Transmission lines can actually be used not only to transfer reactances but also to simulate them. The latter feature is commonly used when stub matching is employed to simulate the necessary inductive or capacitive reactance to correct a mismatched transmission line condition. By a combination of using a lumped reactance at the end of the stub and the effect of the stub itself, almost any value of inductive or capacitive reactance can be created. The reactance so produced can have quite high Q and a low power factor depending upon the quality of the lumped reactance and the losses of the transmission line. By using the proper length and/or termination for a transmission line, it can also reflect an open or short circuit and be used as a remote switch.

Fig. 2 shows how a length of transmission line also can act as either a capacitive or inductive reactance. The chart shows how a short circuited stub can increasingly act as an inductor until it is ¼λ long and then start simulating a capacitive reactance beyond ¼λ. If the stub were open-circuited, the

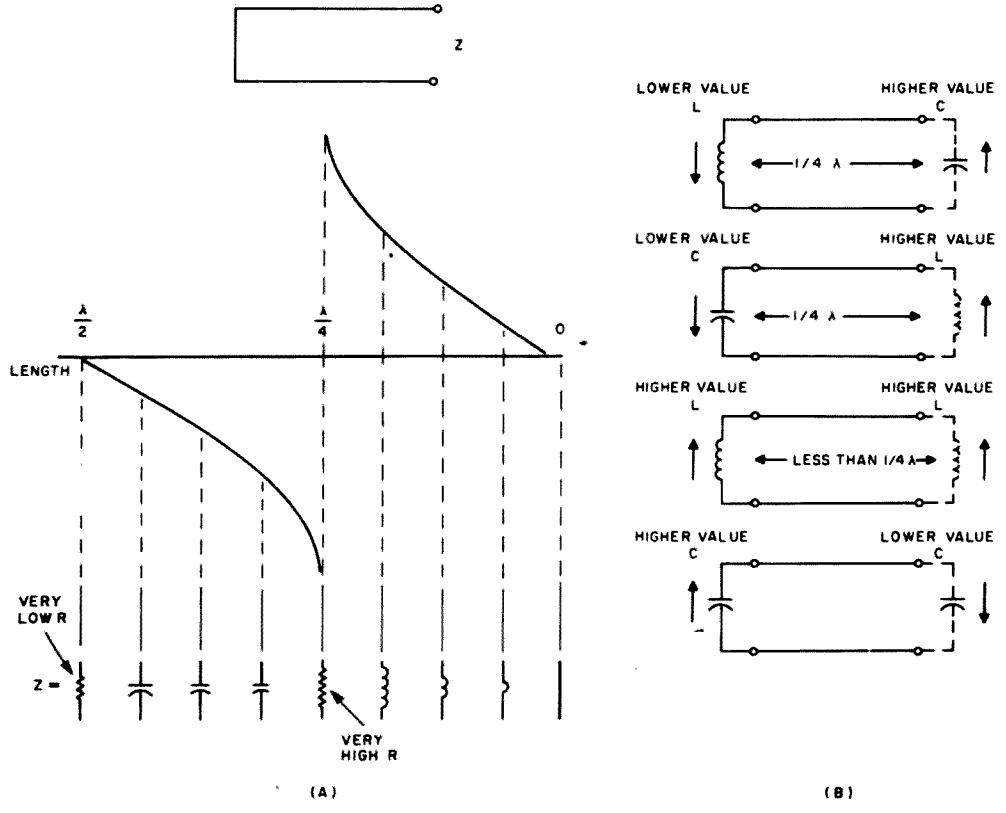

Fig. 2. (A) illustrates how length of transmission line can simulate a series of reactances depending upon its length. (B) shows some of the transfer reactances possible when a lumped reactance is used on the end of a stub. A line exactly ½λ long will transfer exactly the same value as the lumped reactance.

opposite reactive condition would apply. That is, capacitive reactance would be produced until the stub were ¼λ long and then at exactly ¼λ length it would act as a short circuit.

For those who don't mind a bit of math, the reactance produced by the stub when up to a ¼λ long is:

X_L (short circuited stub) = Z tan (2π L/λ)

X_C (open circuited stub) = Z/ tan (2π L/λ)

Z is the impedance of the transmission line used to make up the stub and L/λ is the line length in wavelengths. The physical line length is affected by the velocity factor (usually .66 for coaxial lines) and shorter by that factor than a free-space wavelength.

Although the reactance values repeat as the stub is made odd multiples of a ¼λ long, such long lengths should be avoided if possible. The highest Q will be obtained when the stub length is less than ¼λ. Once one knows the reactance produced by the stub, one can calculate or look up a reactance graph to determine how many microhenrys or picofarads are produced at any particular frequency.

Also, to obtain the best Q, a cable of the lowest loss possible should be used and also one with an inner conductor radius to inner radius of outer conductor ratio of 3 to 5. Not all cables can satisfy the latter criterion, RG/59 cannot, for example. RG/58 and RG/14 both are usable and the latter cable is particularly useful, although it is a bit large (.55" diameter) to satisfy the requirement for low loss and the proper geometry for high Q as a stub.

Short or open-ended stubs alone are limited in ability to produce simulated values of capacitance or reactance simply because of the fixed impedance of the cable used. Replacing the short or open-ended termination with a lumped reactance will, however, extend the range to any desired value. The terminal reactance produced by a stub with a lumped reactance at one end can be calculated or found by a Smith chart plot for various stub lengths. Reference should be made to an antenna or transmission line manual for the method. However, as a general indication of what effect lumped constant termination will have in order to experimentally determine the required reactance, **Fig. 2** can be used as a guide.

Practical Application

Fig. 3 shows how the principle outlined for transfer of the center-loading reactance can be applied. By using the proper value of loading reactance, the overall antenna is resonated either as a ¼ or ¾λ vertical, and so its feed point impedance will match a 50-ohm transmission line directly. The coaxial line used to transfer the base reactance is placed inside the lower element of the antenna. The reactive components themselves can be placed in a shielded enclosure, if desired, but note that both sides of the coaxial transfer line must remain insulated from ground. There will be some radiation from the coaxial transfer line although the portion enclosed in the lower antenna section will not cause any problem. The exposed portion can cause various problems, including pattern distortion of the vertical if it is made too long. Basically, the method of reactance transfer was meant to function with the physical reactance at the base of the antenna and not 100 feet away. Therefore, the dimensioning of the antenna sections and the length of the coaxial transfer line must all match to achieve proper operation of the antenna on various bands and positioning of the base reactive elements.

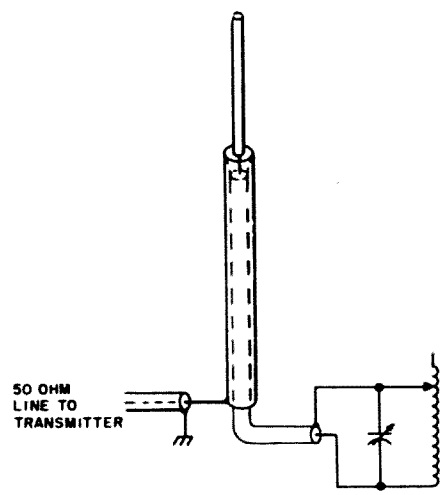

Fig. 3. Coaxial line placed inside lower antenna element to effect reactance transfer from base to junction of upper and lower antenna elements.

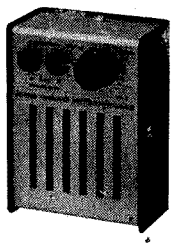
With some care, many combinations can be found that will work. One combination that was experimented with used a standard 10 foot TV mast as the antenna lower element and a smaller diameter 5 foot tube, insulated



from the lower element, as the top element. inside the ten foot section. Since ½λ of this cable on 10 meters was 10.8 feet, it provided a very convenient length to the base of the antenna. Either a B & W stock 3905-1 coil (6 TPI, 2½" diameter) or a 500 pf variable capacitor was used to resonate the antenna, depending upon the band and the antenna's mode of operation.

On 10 meters, some slight inductance was used at the base to make the antenna operate in a ¾λ mode in order to match the transmission line to the transmitter. On 15 meters, capacitive reactance was used to make the antenna operate in a ¼λ mode. On 20 meters some very slight capacitive reactance was also required. On 40 and 80 meters, the transfer line length is quite short in terms of wavelength and additional inductive reactance at the base was used.

Tuning of such an antenna can initially be done using an SWR meter in the transmission line to the transmitter. One should try both the inductive and capacitive element at the base on each band, varying their value until the SWR is brought down as close to 1:1 as possible. Generally, the minimum amount of reactance that will achieve resonance should be used since additional reactance means additional losses. Some confusion will occur on the higher frequency bands because the length of the transfer line and antenna may allow various combinations of base reactances to resonate the system. The only solution in such a case is to use a field strength meter or, preferably, check signals with a distant station to determine which reactance value produces the best radiated signal. Once the proper reactance values are found, they can be bandswitched, if desired, although the tuning does become critical on some bands; a better solution might be to switch the inductor and capacitor (with various taps on the former) and use a simple tuning chart on each band to locate the correct settings.

With a vertical antenna, the transfer of the loading to the base does not affect the fact that either a radial system or good ground connection must be provided if the antenna is always operated in a ¼ or ¾λ mode for direct match to a 50 ohm transmission line.

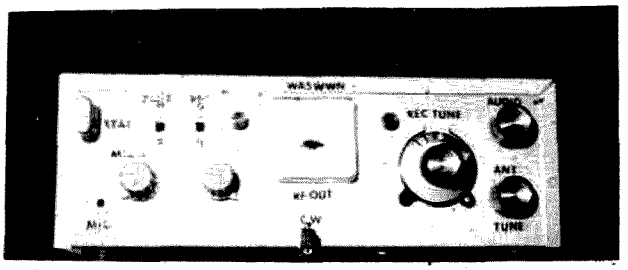
Summary



The method presented for transfer of the center loading in an antenna to a more convenient location presents various interesting antenna construction possibilities aside from the one described.

If a location is used where no adequate ground connection is possible, it would seem possible to use the reactance transfer idea to resonate the antenna in a ½λ mode. The base of the antenna would then be at a high impedance point and an antenna coupler would be necessary to couple to a coaxial transmission line. Another approach to make an antenna with less ground dependence would be to form a dipole antenna, center loading each element via a reactance transfer cable to the center of the dipole.

Removing the physical reactance a distance away from the base of the antenna presents the problem of line radiation which was mentioned. A possible solution to this problem may be the use of triaxial cable with the outer shield grounded and the inner shield and inner conductor used for the reactance transfer. How long the cable could be while still retaining good loading Q and without having the tuning become too critical are questions that only trial and error experimentation can answer.

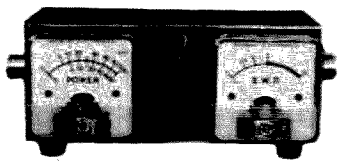
Quazar QRP 40 Meter DSB Transmitter

For several years now I have been trying to make a QRP sideband rig and finally achieved this with the aid of the March 1969 issue of 73 and the article written by WA1FRJ. I had gone through about five different balanced modulators over a period of the past two years and could not achieve any satisfaction until using his method with the toroids. Keeping 18 volts on the transmitter, no carrier is noted. A 20v and above carrier can be observed on the rf output meter that is incorporated in the transmitter output. The diodes in the modulator do not seem to be too critical, but keep the forward resistance of each diode as close as possible. I used the usual junk box diodes from a printed circuit board I bought for 29¢ and with no designation on them (same goes for the direct conversion receiver I built out of another article). Possibly the hot carrier diodes may work better but I have achieved good results with WA5NTN who is about a mile from me and has worked patiently in testing the transmitter for the past three months.

The rig works good on CW, too. I have made quite a few contacts and several contacts over 200 miles. With a little patience one could do quite a bit better I'm sure.



Construction notes: Parts layout does not seem to be too critical. Each section of the transmitter was built on a separate module and tested individually in line as it was constructed. I used 1/16 inch circuit boards and breadboarded the components on each board and made the connections on the under side. This allows positioning of each

Simple Compact Six Meter Bandpass Filter

(TVI eliminator, or how to keep your happy home happy)

Would you like a good filter that really works, low loss, doesn't need to be retuned if you QSY 50 khz? Well, this one can be built in less than an evening. Then you can hook it up and forget it. Total cost with all new parts is only $4.42.

When I started on six meters in 1963, I naturally had my share of TVI. So I built the low pass filter for six meters from the *Radio Amateur's Handbook*[1]. This did help but didn't eliminate all the complaints. Also it had about 2-3 db loss besides. So I really wasn't too happy with it but suffered the loss in order to stay on the air.

Then, about two years ago, I requested and received several Amperex Application Reports[2]. One of these was Report No. S-124, "Designing Varactor Triplers."

Sounds far out? I thought so too until I looked in the back and saw information for three bandpass filters with low insertion loss and good skirts. The filters are for 50 mhz, 150 mhz, and 450 mhz.

The 50 mhz filter had 0.4 db insertion loss at just under 50 mhz but the nose of the curve was very sharp and appeared to be about 1 mhz wide at 1 db down. So I constructed a filter based on this information, but with less spacing in order to slightly overcouple and broaden the nose of the curve while still keeping good sharp skirts. The result was a filter with a minimum loss of 0.3 db, less than 1 db loss from 50 to 52.5 mhz, and better than 40 db down 10 mhz away.

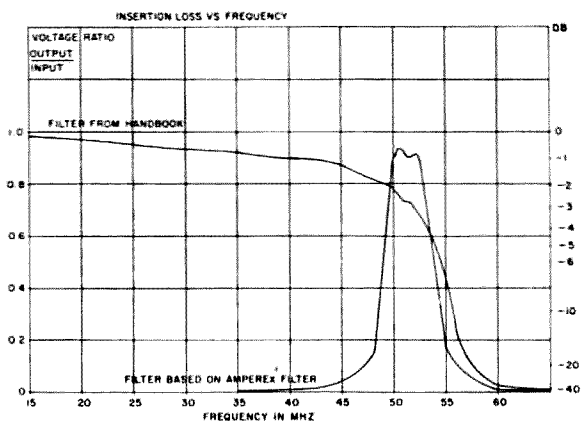

Fig. 1. Graph of filter response.

I plotted the response of both filters in Fig. 1, so you can compare the characteristics. Both filters were peaked for best response and lowest loss at 50.5 mhz. (Note: The low pass was constructed in a steel Minibox which might have added some loss at the higher frequencies.)

The filter is built in a Bud Minibox, CU3003A with all parts mounted on the "U" portion. This is 2½ x 2½ x 4 in. The coils are 7 turns no. 12, 5/8 I.D. One is wound lefthand, and the other righthand. The turns should be evenly spaced and be 1 5/6 in. from the top turn to the bottom turn. Solder directly to the coax connector at exactly one turn from the bottom. For powers up to 500 watts, use Johnson 148-4 capacitors. Above that, use something with a higher voltage rating. Mount the coax connectors at a 45 degree angle to the edges of the box and use a solder lug on the lower screw to ground the lower end of

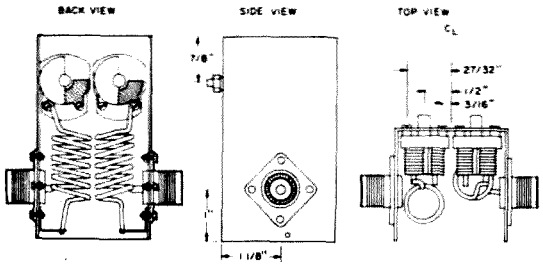

Fig. 2. Filter dimensions and construction.

the coil. When you are finished, the coils should be spaced 1 inch apart. Position as shown in Fig. 2.

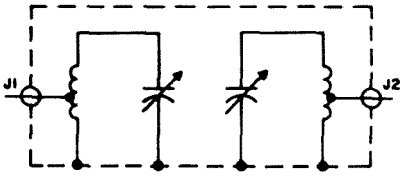

Fig. 3. Schematic.

To tune the filter, insert it in the transmission line, set your receiver to 50.5 mhz, and tune for maximum noise or signal. Then transmit and notice the reduction in TVI. I think you will be quite pleased. Look for me the next time 6 is open, because otherwise I can't get out of this valley. Out here, the dial impulses from the telephone tear up the TV more than my 45 watt homebrew with the filter installed.

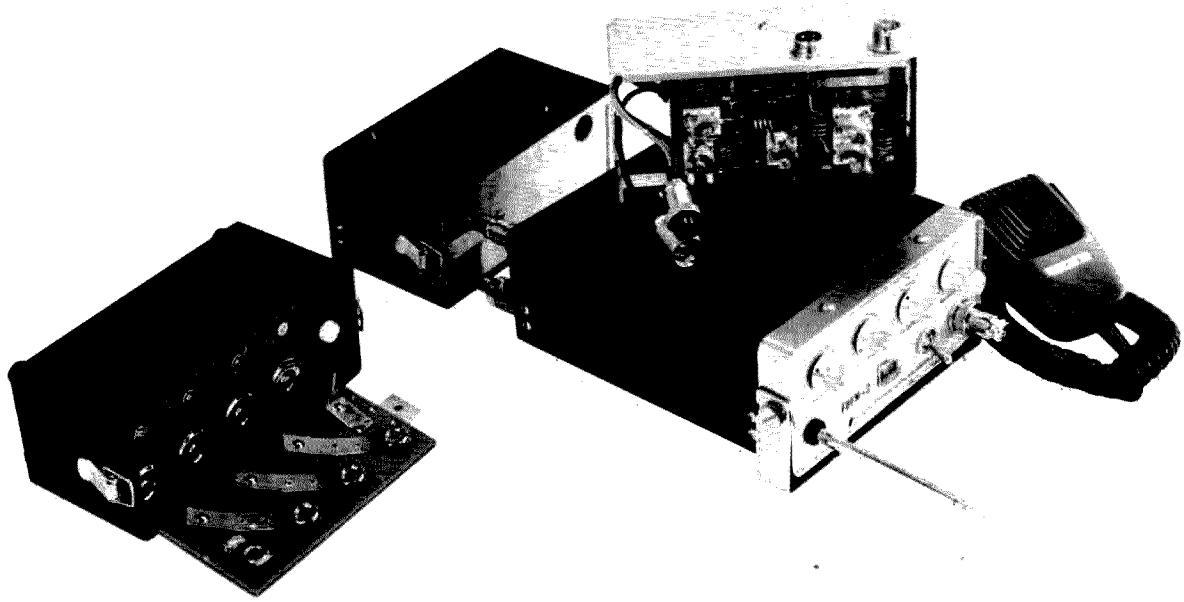

Fig. 1. Varitronics FDFM-2 uses modular approach. Snap-on elements change basic low-power transceiver from mobile to portable, to high-power base station.

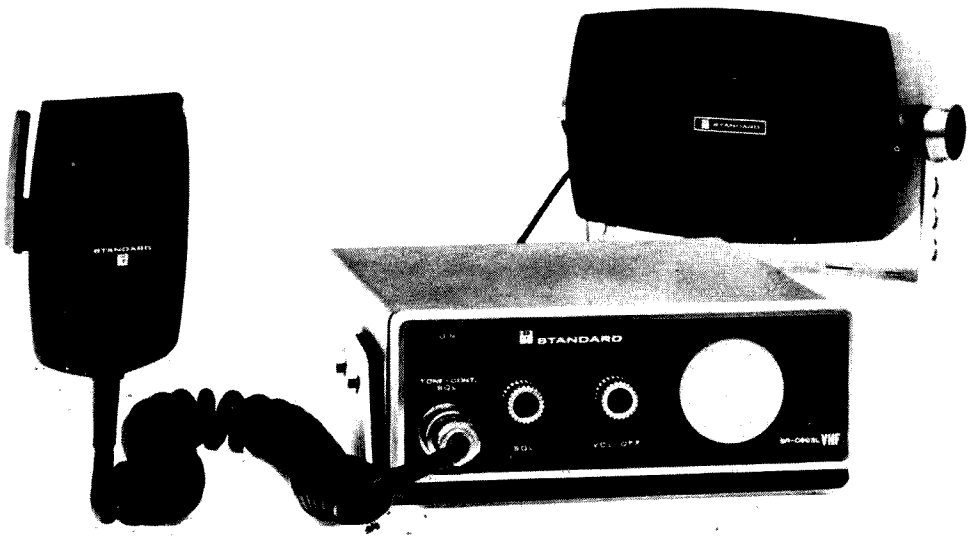
Low Cost Electronics: Japan's FM Invasion

Two years ago the door to FM operation on the VHF bands was narrow indeed. The only way an amateur could get started was by converting FM units that were designed for two-way use in the neighboring commercial spectrum. As a result, most amateur FM operators were either endowed with special technological skills or were close friends of individuals who were thus endowed. A survey of operators conducted by FM Magazine in late 1967 showed that 72% of all active FM'ers were associated in some way with the commercial radio service—as technicians, First- or Second-Class Commercial licensees, or as two-way users.



Today, a similar survey would likely show a reversal of that trend. Thanks to enterprising American businessmen and clever Japanese engineers, VHF amateur FM has become one of the least expensive and easiest-to-open doors to ham radio.

The Inoue line of amateur FM units, distributed in the U.S. by Phoenix-based Varitronics, Inc., serves as an example of applied Japanese knowhow. Designed modularly so they can be used in every conceivable application for a variety of individual interests, the units are high power or low; portable, mobile, or fixed; crystal controlled but multiple channel.

The basic unit, shown with three snap-on modules in **Fig. 1**, is an underdash-mounting, six-channel, low-power mobile unit that is ready to go when a 12V source and an antenna are connected. In this service, the transmitter puts a little over a watt into the antenna. And if a watt is insufficient, the module shown behind the transceiver will up the output to better than 20W. The modular class C amplifier mounts flush with the rear of the basic unit and is held on by a suitcase-type snap on each side. (The transistorized amplifier is shown disassembled atop the transceiver.)

Fig. 2. Base station module, built in case of same configuration as transceiver, permits high/low power switching and operation from 115V power source.

The narrowband 12-channel Standard FM transceiver comes equipped with simplex crystals for 146.94 MHz. Designed for portable or mobile operation, unit packs a 5W punch and draws only 100 mA in standby mode. Frequency error rated at 0.0005%, with a receiver sensitivity of 0.3 μV. (Standard Communications Corp., Torrance, California.)

A battery module (lower left in photo) converts the unit to a hand-held transceiver. The battery pack uses eight D-size flashlight cells in series and provides enough sock to keep the radio going for about 15 hours of typical intermittent duty. In portable use, the transceiver stands up on end so that the telescopic whip (protruding from the face of the pictured unit) can be extended vertically. The whip antenna is a screw-on type and is removed for mobile or fixed-station use.

So that the Varitronics FDFM transceiver will be capable of gobbling up every possible morsel of business in the many-faceted FM market, the company is distributing a power supply/amplifier module designed around the same case as the basic transceiver. This unit, shown in **Fig. 2**, contains a converter that supplies 12V dc from an ac source of 115V, as well as a modified version of the class C amplifier. A panel switch permits optional use of the amplifier.

The prevalence of repeaters on 2 meters has opened a whole new vista in useful products for communications. Consider, for example, the limited usefulness of a low-power VHF hand-held transceiver. For point-to-point operation, the range and utility would be restricted to near impracticality except at hamfests, transmitter hunts, and other close-in gatherings. But one of the key features of a repeater is its ability to extend the coverage of even the lowest-powered transmitters and the least-sensitive receivers. Now a number of firms are cashing in on this feature by importing a variety of miniaturized communications devices.

The "Handicom" is one such unit. Designed specifically for use with repeaters, the tiny two-channel transceiver (**Fig. 3**) boasts a receiver sensitivity of 0.4 μV for 20 dB of noise quieting and a transmitter output

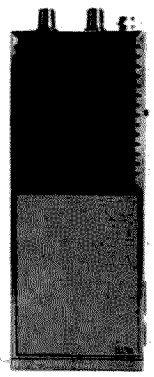

Fig. 3. Handicom transceiver is self-contained 1.6W hand-held unit with sensitive superhet FM receiver, designed especially for operation with repeaters. Comes with two-channel capability so point-to-point operation can be assured when repeater is not in range.

Fig. 4. Allied VHF monitor receiver is one of the first to include the FM portion of the 2-meter spectrum as part of its regular tuning range.

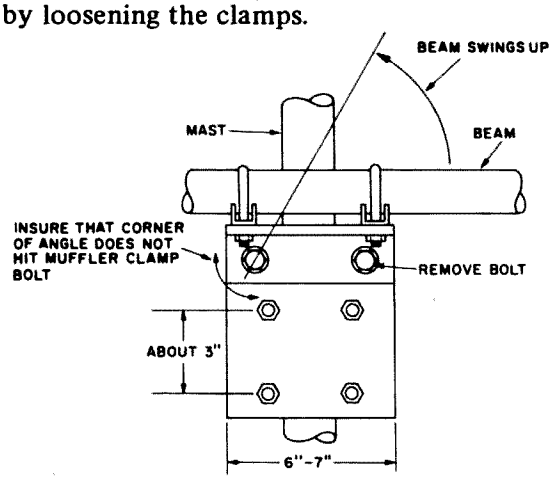
power of 1.6W. The Handicom, distributed by Telco (Pomona, California), comes equipped with rechargeable batteries, charger, integral meter, removable whip, and all the other accessories typically furnished with Japanese-made radios.

Even some of the giants are finding amateur FM a lucrative market. Allied Radio is pushing a low-cost monitor receiver that tunes from the commercial band all the way down to the bottom of the amateur FM spectrum (146.0 MHz). The Allied unit, **Fig.4**, has a self-contained 2-1/2 in. speaker, a swivel telescoping whip, plus provisions for an external antenna and a 115V ac adapter.

. . . K6MVH

Easy Tuning of the Beam

Any time a beam antenna is erected, we run into the problems of how to get to the elements and matching device to tune the beam. **Fig. 1.** shows a method for tilting the boom so the elements are readily available to a man on the tower. Rotation of the boom might be necessary and this is accomplished by loosening the clamps.



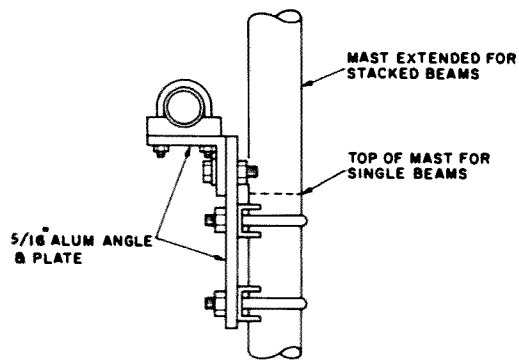


Fig. 1. Construction details of the tilting device.

With one man stationed on the tower, a rope tied to the boom, and the bolt removed, he can bring the elements and matching device within easy reach. Since the beam is off center, it will right itself by letting up on the rope.

...P.L. Simandl, K9SQV

Dial Drive Repair

"The Heathkit SB series of ham kits are, in general, a fine piece of electronic equipment." This is the kind of statement you can hear on almost any ham band where you might listen. There is, however, one bad comment one does hear once in a while: "That darn dial drive." (It must be pointed out that the dial drive is a real joy to most: however, to some...) I became one of the few after building two kits (an SB-300 & SB-400) with no problems. As is normal with such endeavors, it was a kit I was building for a friend that "went amuck." The problem was that no matter how hard I tried to align the thing, the drive would operate for a short time, and then, for no reason, just quit.

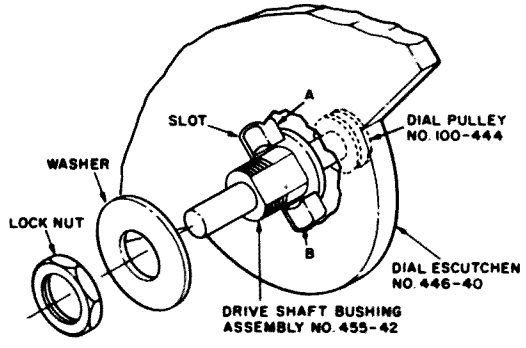

Fig. 1. Cut away drawing showing added "shims" (A&B).

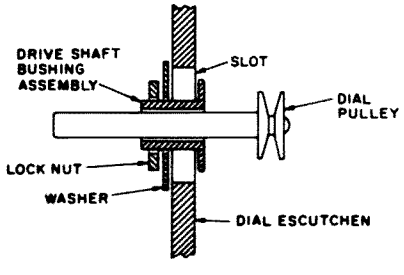
It seems the problem is in the fundamental design. Once the "Dial pulley" (Heath part 100-444) is pressed down and locked in place with a lock nut, sometimes the unit just "walks" up on the slot in the escutchen and slips. (The plastic material used to make the escutchen prevent the builder from making it too snug.)



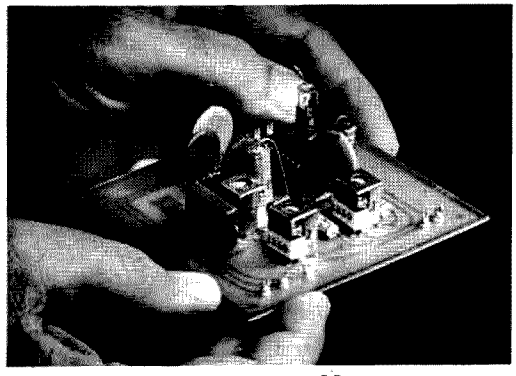


Fig. 2. Profile (No shims).

To eliminate the problem, I simply made two wood shims (one above and one below the "dial shaft bushing assembly") as shown in Fig. 1. This simple addition removes all the stress from the plastic escutchen and allows the dial to operate 100% of the time with the lock nut only "finger tight."

Mobile CW

After operating CW mobile in one of the heaviest auto populated sections in the U.S.–the Los Angeles freeways–for over a year and receiving comments from, "how brave you are" to "what an idiot," unspoken but unmistakable, I decided to write about some of the tricks that make mobile CW a real ball.

First, mobile CW is hopeless unless you are a true CW man. You must be motivated to communicate by that wonderful pure code and give up the "by gollies" and "fine business, here" jazz of SSB. Mobile will never convert you to a CW man, but a CW man can be converted to mobile.

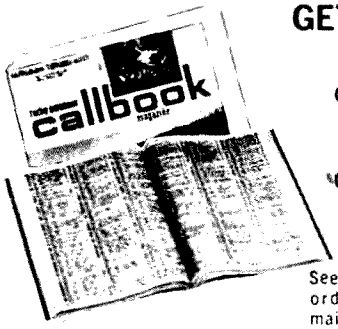
Second, you must be prepared to accept the frustration of having your report or the DX call blanked out by the ignition QRN from that miserable little VW who is staying right behind you staring at that big whip. Murphy's law reigns paramount here. When you have been waiting for 30 miles to hook that JT1 just invariably when he calls you, on comes the ignition or power line QRN. You will begin to notice that all the major roads and freeways follow the path of the highest QRN. I am sure they put in the power poles first and built the roads next to them. Also, you will find yourself looking for different ways to drive to work to avoid what I call "QRN Alley" or else you time your QSO so you send in the high QRN areas and receive in the low–tricky, but possible.

The basic solution is simple. Acquire the patience of Job and train your ears (what the headshrinkers call "the cocktail party syndrome" where you can pick out one voice and copy it solid over other masking voices) to copy through S5-S7 QRN and develop the tricky use of audio filters, rf, and audio controls. The code can sound mighty strange by the time it gets through all those windows, but it can be copied solid. As a bonus, your home receiver will sound so very nice and quiet to you that you keep checking to see the antenna is connected–sort of like after you lift heavy weights for a long time then light weights seem very light. All this is for free.

Third, you must be prepared for strange looks, staring kids, and slow shaking of heads as people pass you on the freeway. Especially when your car is a white Cadillac, the whip sticking way up high as it is mounted on the center of the car just back of the rear window forward of the trunk deck, earphones on, and then have a beard–like me. I have a speaker mounted by my left ear, but as I like to chase DX even mobile, I use phones–in fact, I most always use phones as a hangover from the "every signal is weak" old days. If you are shy–forget it.

This article describes what could best be called a "human factors approach." It is not a construction article, as many excellent ones have already been written, but it shows one way to integrate the amateur, the driver, the car, the freeway, and the rig all into one smoothly operating loop to dramatically lessen the hazard of operating CW while driving.

My basic "human factors" design requirement for CW mobile operation was the rig and all controls had to be operated without the driver ever taking his eyes off the road. To do this, all controls must be close enough to the driver and capable of operation without reaching *or* looking to reach.



As each mobile installation is different, the first step is to make what the aerospace industry calls a "mock-up," or a simulation of the rig, controls, and mounting in the car. This can be done by supporting the rig, controls, SWR unit, etc., with wood blocks, rope, books, beer cans, etc., and using stiff cardboard and tape to simulate the structure of mounting of the final installed operating position of the rig, the key or paddle, and

SWR unit in the front seat of the car.

Then, the second step is to shut the doors, move the seat to the driving position, start the car and operate all the car controls like the lights windshield wipers, steering wheel adjustment, air conditioner controls and outlets, ashtray, glove compartment—don't miss a one. Obviously, in all cases they should not be completely obstructed by the rig or supporting mounts. In specific cases, a compromise can be made. In my installation the governing factor was the dashboard ashtray. I compromised on using half of it. I pull it out until it hits the rig and that gives enough clearance to use the lighter and half of the ashtray. I don't smoke while driving, but girls do!

The third step is to simulate a complete QSO operating all the rig controls and key with your eyes doing just the normal (?) scan of odometer, fuel and temperature gauges, rear mirror, side mirror, and the blonde in the next car. In no case look at the rig—except for the first quick glance to see if you are in the band. To do this with a flick of the eye, mark on the dial in black with

tape or paint a ½ inch bar at each band edge so as long as you are centered between the black bars you are safe. Now, make the final adjustments to the "mock-up" so the basic design objective is met; i.e., operation of *all* controls without looking or stretching to reach them.

Great—if you feel silly after this little experience, then you did it just right, but you would be amazed at how much time and money is spent and how seriously such simulation is done in the aerospace industry.

My installation, which resulted from the "mock-up," was a little wooden desk made from soft pine. The desk bottom is contoured to fit over the floor hump and is secured to the car floor with angle brackets. The art of drilling through the car floor into a clear space for nuts and washers underneath is sheer black magic. However, some judicious measuring from the car edges or other reference point helps not drilling through the muffler or a brake line.

The desk is made so the Swan 500 sets into a recess on top placing the front panel on a slanted plane easily reachable and seeable from the normal driver's position. The rig is held down in the recess with one bolt and a wing nut.

The desk has a small "L" shaped flat top going in front and along the left side of the rig. The front portion holds a paper pad and the left hand side of the "L" has the vertical plane of the right edge of the steering wheel. Thus the driver's hand just slips off the wheel onto the desk and the fingers drop on the key and paddle with an arm rest. The hand key and the keyer paddle are mounted in the same position on the desk. The keyer paddle is mounted vertically at an angle above the hand key so the paddle finger plates are forward and above the hand key knob—just far enough away so the fingers can handle the hand key without hitting the paddle plates. In this manner when your hand falls off the wheel, your fingers are on both the paddle and the band—so without looking you can move your fingers to work whatever key you want. Both keys are installed so if the keyer flunks the course, you still are on the air with a hand key to get in practice for the Extra Class exam. The SWR unit is mounted on the top and back of the Swan 500 where it is visible by glancing over the top of the rig toward the car floor.

All other controls, like the keyer speed control, speaker switch, etc., should be on the left side of the steering wheel to balance up the human factors programming of the rig operation on the right side. An added refinement is to duct some cool air from the air conditioning ducts into the final tube compartment of the rig. After an hour's operating even the dial on the Swan 500 would be hot to touch. After building a plenum chamber on the outside of the enclosure right next to the final amplifier tubes and installing a duct from the air conditioning system, the whole rig is cool. This lets the power output stay up and must prolong component life. Even the use of ambient air from the blower alone has significant effect. So far, no one has commented on the fact I disconnected the entire car's right hand air conditioning for this worthy purpose! It is an interesting and uncomfortable example of thermodynamics to feel how much heat can be transmitted into the front seat area from a little black box burning up those watts not going into the antenna.

If you have been faithful to the design objectives, you now have a "human factors" designed mobile installation. You should be able to turn on the rig, tune and establish control without looking or reaching so your head bobs down. In the real world you will find many clear opportunities to look while stopped in freeway jams, but you will be amazed at how quickly you can scan everything you need to see.

One word of warning while driving: By all means avoid the trap of looking at the rig and trying to troubleshoot if it doesn't work. The feeling is almost irresistible to try to get it working again—right now. Don't do it! Shut off the rig and listen to AM/FM until you get home or else get off the freeway and stop. It cost me $450 over the deductible insurance one rainy night on the freeway trying to get the rig working. It started working just as I slid off the side and down the embankment—a sadder, but wiser CW mobile type. Human factor engineering helps, but it can't think for you.

Getting Your Extra Class License

STAFF

Part XII: Semiconductors

Just a little more than two decades ago, a trio of Bell Telephone Labs researchers put together a device which had all the external characteristics of a resistor—with one thing added: it would transfer a signal from one circuit to another, and if the circuit was properly put together it would amplify the signal in the process.

The learned gentlemen coined a name for their device by combining the words "transfer" and "resistor" into "transistor." Today, it's hard to realize that the transistor was unknown 25 years ago, and even 15 years back was pretty much a laboratory curiosity. Now, of course, it's just about the usual thing to find transistors in almost any receiver, and not too unusual to find them in low-power-level stages of a transmitter as well.

Semiconductors—of which the transistor is only the most widely used example—are such an important part of the art of electronics today that the Extra Class examination includes a number of questions dealing with them. Those questions are our subject this month.

The official FCC study list of questions includes five specific questions dealing with semiconductors in its total of 90 questions covering the entire knowledge required for would-be holders of the Extra Class ticket. These questions are: 15. Define the alpha cutoff frequency of a transistor. How is this parameter of use in circuit design?

38. How are the emitter, base and collector of a transistor biased for amplifier operation? How are they biased for cutoff (open circuit) and saturation (short circuit)?

39. How do NPN type transistors differ from the PNP type? How does their bias differ?

52. What is the phase relation between the input and output signals in the common-emitter, common-base, and common-collector transistor circuits?

84. Compare silicon and vacuum tube diodes. What is meant by the "forward voltage drop" of a conducting silicon diode?

Question numbers, as always, are those assigned in the Commission's study list.

We'll follow our usual procedure. Rather than answering these five extremely specific questions with equally specific replies, we'll reword the questions into less specific queries which cover the same material but much more as well. Then we'll hunt for answers to our more general questions, and along the way come up with the answers to not only the specific study list questions, but most of the similar ones which may appear on the actual exam.

All our questions deal with semiconductors, so let's make our first general question simply "Why Is A Semiconductor?" The answer to this will provide answers to both questions 39 and 84, as well as a foundation for our subsequent questions.

From there, let's find out "How Do Transistors Amplify?" This will provide partial answers to questions 38 and 52, as well as to the second part of question 39.

When we know how transistors amplify, then we can ask "What Factors Affect a Transistor's Amplification?" and that will bring us into the answer for question 15. To wind up our examination of transistors, we'll ask "Is Amplification All?" and that will get us an introduction to the world of semiconductor switches. This subject in itself could fill several large volumes, but affects only a part of question 38 on the study list.

For our final question, we'll drop transistors and ask "How About The Rest Of The Family?" Here, we'll take very brief looks at some other members of the semiconductor clan and compare them with their more historic equivalents.

As always in this study course, we run the risk of oversimplifying complex subjects when we attempt to compress an entire field of study into one or two articles. This time, the risk is higher than usual—because semiconductors came to us from physicists rather than from more mundane experimenters, and the whole basic theory is deeply intertwined with the physics of subatomic particles.

Fortunately, nobody needs to be an atomic physicist to get a fairly clear understanding of how semiconductors work. This was made abundantly clear more than 10 years ago with the publication of Department of the Army Technical Manual TM 11-690, "Basic Theory and Application of Transistors." In that 253-page volume, only one chapter required any knowledge of mathematics—and that chapter could be skipped without any harm at all, because its purpose was to provide the algebraic proof that the "equivalent circuits" used by transistor-circuit design engineers actually do represent transistors accurately. And the math required to get through that single, optional chapter was hardly any more complicated than that necessary to apply Ohm's Law!

We have leaned heavily upon the approach and examples used in TM 11-690 in preparing the first 4/5 of this installment, because the basic theory has not changed and 11-690 does provide an accurate picture of it without introducing errors because of oversimplifying. The final discussion, though, involving "the rest of the family", is based upon a number of other sources, because the kinds of semiconductors known have increased hugely in the decade since 1959.

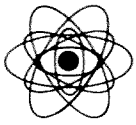
Why Is A Semiconductor?

To have any understanding of how a transistor operates, we must have a fairly clear idea of what a semiconductor is and why it can operate. But to get that idea clear, we must first turn our sights to something even more basic—the theory of the structure of matter.

We already know quite a bit about this theory, although we may not know it by name. It's the theory which tells us that electrons exist!

Let's start out assuming that we know nothing about it, though, and begin at the very beginning by defining "matter" as "any substance that has weight and occupies space." This includes all gases, liquids, and solids.

Chemists tell us that all matter is composed of either "elements" or "compounds," with most of it being "compounds." An element is a substance that can neither be broken up into other substances by chemical action, or made from other substances. A compound is any substance which is not an element. Such things as copper, aluminum, oxygen, and hydrogen are elements. Water, rust, and salt are compounds. Water is a compound of two parts hydrogen and one part oxygen, but its chemical properties are very different from those of either of its elements. Salt is made of equal proportions of the metallic element sodium and the gaseous element chlorine, both of which are highly poisonous in their pure form—but salt is essential to life.



Whether a substance is an element or a compound, it is made up of many "molecules." The molecule is the smallest particle of any substance which can exist by itself and still retain its chemical properties. The molecule is composed of atoms, which are the smallest particles of *elements* that can take part in chemical actions. A molecule of water contains two atoms of hydrogen and one atom of oxygen. A molecule of gaseous hydrogen contains two atoms of hydrogen. A molecule of salt contains one atom of sodium and one of chlorine.

Since there are at least 102 elements, 92 of which occur in nature and the rest of which are man-made in nuclear experiments, there are at least 102 different kinds of atoms. At one time it was thought that the atom was the smallest particle of matter—but the advent of our electronics art brought that belief to an end. To explain the action of electricity and vacuum tubes, the physicists had to move on into the world of subatomic particles.

By now, they have moved still another step smaller into "subnuclear" particles as well, but we don't need to carry things that far. Our purposes will be adequately served when we meet the three major subatomic particles: the electron, the proton, and the neutron.

Nobody has actually seen any of these, so what follows is only theoretical. The theory, however, has withstood the test of time since 1889, and has fit all observations, so we assume that it is an adequate picture of the atomic structure.

If we could enlarge an atom some 100 million times, it would appear to be about the size of a penny. We could then distinguish its two major parts (Fig. 1), which are a central nucleus and a cloud of electrons orbiting around the nucleus much as the planets of our solar system orbit the sun.

ATOM MAGNIFIED 100 MILLION TIMES

ATOMIC NUCLEUS X 1 BILLION

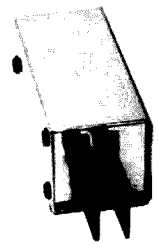


Fig. 1. Atom is smallest unit of any element. Views shown here are those described by current atomic theory; nobody has ever seen either so they may not be correct. Top view shows major parts of atom—central nucleus and orbiting clouds of electrons surrounding it. Electrons orbit in "shells" which represent definite energy stages. Nucleus is composed of neutrons and protons as shown in lower view.

At a billion time enlargement, we could see that the nucleus resembles a bunch of grapes, and contains two different kinds of particles. This part of the atom provides nearly all its mass. Both kinds of particles in the nucleus weigh the same—1850 times as much as the electron. One of the particles is charged while the other is neutral; they take their names (proton and neutron) from this fact. The proton has a positive electrical charge.

The positive charge of each proton is balanced by an equal negative charge on the electron. It's still an open question just what an electron is; some feel that it's merely a

Don't look for a gift horse in a haystack.

Build this exciting Schober Consolette Organ for only *$1040!

*Includes finished walnut console. (Only $793 if you build your own console.) Amplifier, speaker system, optional accessories extra.

You couldn't touch an organ like this in a store for less than $1800—and there never has been an organ of the Consolette II's graceful small size with 22 such pipelike, versatile voices, five-octave big-organ keyboards, and 17 pedals! If you've dreamed of an organ of your own, to make your own beautiful music, even if your home or budget is limited, you'll get more joy from a Schober Consolette II than any other "home size" organ—kit or no kit.

You can learn to play it. And you can build it, from Schober Kits, world famous for ease of assembly without the slightest knowledge of electronics or music, for design and parts quality from the ground up, and—above all—for the highest praise from musicians everywhere.

Send right now for the full-color Schober catalog, containing specifications of all five Schober Organ models, beginning at $499.50. No charge, no obligation. If you like music, you owe yourself a Schober Organ!

The *Schober* Organ Corp., Dept.
43 West 61st Street, New York, N.Y. 10023

☐ Please send me Schober Organ Catalog and free 7-inch "sample" record.

☐ Enclosed please find $1.00 for 12-inch L.P. record of Schober Organ music.

CITY_____ STATE_____ ZIP_____

unit of electrical charge while others feel that it's more than that. For our purposes either idea is all right, so long as we remember that the atom is balanced electrically.

The electrons are held in their orbits by a balance of opposing forces, including electrical attraction and repulsion. The orbiting electrons shield the nucleus so that it cannot take part in ordinary chemical reactions, but the number and kinds of particles in the nucleus determine the mass of the atom and how many electrons it has, and so are the factors which make one element different from any other element.

In some respects, the cloud of electrons in any one atom is something like an onion. If you keep peeling an onion, you'll never get below the skin—and when you finish you'll find you have nothing left.

Similarly, the orbits of the electrons in each atom are arranged in layers sometimes called "shells." Each shell represents a balance of forces at a specific distance from the nucleus, and each shell can hold only a specific number of electrons. The first (innermost) shell can hold only two electrons. The second shell can hold only eight. The third is limited to 18 electrons, and so forth. If an atom has only one or two electrons, it will have only one shell. If it has 3 to 10 electrons, it will have two shells. With 11 to 28 electrons, three shells are necessary. The outermost shell need not be filled.

Because of repulsion between like charges (and all electrons are negatively charged), the outermost shell (Fig. 2) is the only one able to participate in chemical reactions. Chemists call it the "valence shell," and know its electrons as the "valence electrons," for this reason. The number of valence electrons in any atom determines how that atom will combine with other atoms to form molecules. For instance, hydrogen has only one electron, but the first shell can hold two electrons. Because of this, hydrogen atoms combine to form hydrogen molecules of two atoms each, with each of the atoms in each molecule sharing its electron with the other. Both positions in the shell are now filled, and additional chemical combination is difficult.

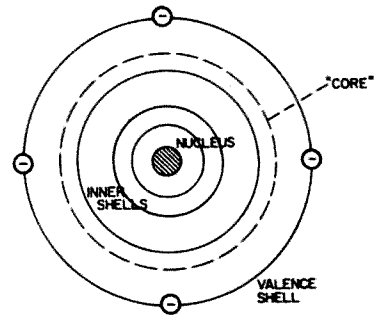

Fig. 2. General structure of atom as it applies to semiconductors is mapped here. Nucleus, in center, is surrounded by electron shells. Outermost shell, termed "valence shell," is only one involved in crystal structure or chemical actions. Nucleus and all inner shells, combined, are called "core" of atom. In crystals, atom cores are fixed into position but valence electrons are free to move to limited degree.

The various kinds of matter may be divided into groups in many ways. We have already seen the physicists' grouping into gas, liquid, and solid. Chemists group things as elements or compounds; they also group by "organic" and "inorganic" structure, in which organic structure includes all compounds containing the element carbon, and inorganic structure is everything else. We will be concerned only with matter of inorganic structure from here on; this eliminates anything which was once part of a living organism.

Another grouping, which is why we've gone through all this in the first place, is into the categories of "conductors," "insulators," and "semiconductors." This actually isn't a very good set of words to use, because no perfect conductor or perfect insulator exists. Everything, actually, is a semiconductor—but some things are more, and some things less, "semi" than others.

Copper, silver, and gold, for example, are considered good conductors because they offer extremely low resistance to the flow of electric current. Air, glass, and mica, on the other hand, are considered insulators because they offer extremely high resistance.

The resistance of any substance is directly related to the valence electrons in the molecules of that substance. If the electrons are relatively independent of any one nucleus, they can migrate easily through the material—and that material is a good conductor as a result. If, on the other hand, the electrons are tightly bound into place and there are

few "free" electrons able to move, then the resistance will be high and we have an insulator.

Our common semiconductors, germanium and silicon, are actually fairly good insulators in their absolutely pure state. They gain their semiconductor properties because of carefully controlled impurities which provide a few free electrons or their equivalent—but before we can see how this is done we must turn from chemistry to physics and look at the structure of crystals.

Most solid inorganic substances are made up of crystals. In many cases the individual crystals are too small to see except through a microscope, but in some cases the crystals are large. A quartz crystal in its natural state (before cutting) is a single large crystal. So is a diamond, or the ruby rod in a laser.

X rays have been used to examine the internal structure of crystals, and from the pictures obtained we have been able to construct models of this internal structure. These models reveal the not-too-surprising fact that the structure of the crystal is determined by the characteristics of the atoms which compose it (not necessarily the molecules), and the somewhat less expected point that each atom is related not to just one adjacent atom or two, but to a number of adjacent, equidistant atoms.

The specific arrangement of atoms in any crystal depends on the size and number of atoms present and on the electrical forces between them. All other characteristics of the crystal depend on these forces between the atoms.

For instance, to turn to carbon crystals momentarily, the carbon atoms in a crystal may take either of two different arrangements. One of them produces a structure which is soft and opaque; we use it (graphite) as a lubricant and to write with. The other produces a structure which is the hardest substance known, and is transparent. Only another diamond will cut a diamond. And the difference between a diamond and a pencil lead is just the difference in arrangement of atoms of the same element.

The structure of a crystal is determined by the valence electrons of the atoms in the crystal. In a crystal, the rotation of one valence electron of a given atom is coordinated with the rotation of one valence electron of an adjacent atom. Such a coordinated rotation of two valence electrons (one from each of two adjacent atoms) is called an "electron-pair bond" by physicists, or a "valence bond" by chemists.

The electron-pair bonds cause the nucleii of the two atoms involved to be attracted toward each other, while the positive charges on the nucleii repel each other. When these forces of attraction and repulsion balance, the crystal structure is in "equilibrium."

Once a valence electron is involved in one electron-pair bond, it cannot participate in any other such bonds, nor may it drift through the substance as a free electron. Thus, in a crystal, each valence electron of each atom can form an electron pair bond with an adjacent atom.

The first element widely used as a semiconductor, and still one of the most popular, was germanium. This element has four valence electrons in each of its atoms, and so each atom in a crystal of germanium is linked by electron-pair bonds to four adjacent atoms. The resulting crystal structure looks something like the sketch in Fig. 3, with one atom at the center of a pyramid and its partners at the corners of the pyramid.

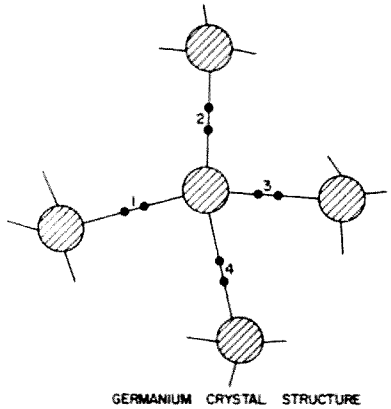

Fig. 3. Germanium and silicon, the two most widely used semiconductor materials, each have four electrons in their valence shells and so form crystals in which each core is joined to four other cores by electron-pair bonds. Other materials may also fit into the structure, with electrons either missing from bonds (holes) or left over (free). This produces P-type and N-type material, respectively.

We have already seen that crystals may be small or large. The crystal structure we have just examined is that which exists *inside* the

crystal; at the edges, of course, there are no adjacent atoms to link to. Because of this, materials which exist as many small crystals (such as most metals) behave considerably differently from those which exist as a single large crystal. In particular, a polycrystalline (many-small-crystals) substance is likely to be a good conductor because the valence electrons in the outside atoms of each crystal are free to drift through the materials, and a single-crystal substance is likely to be a good insulator because almost all its valence electrons are fixed in place as partners in electron-pair bonds.

What we call semiconductors are always single-crystal substances. If every atom in a crystal of germanium is actually a germanium atom, then the crystal acts as an insulator. However, if a very few (about one in ten million) atoms of some other substance with either fewer or more than four valence electrons are in the crystal, the valence electrons will not all be fixed in place.

A number of such other substances are able to fit into the structure of the germanium crystal. Arsenic, phosphorus, antimony, and boron, all of which have five valence electrons rather than four, will fit in. So will aluminum, gallium, and indium, which have only three valence electrons.

The substances with five valence electrons are called "donor" materials because they "donate" an excess valence electron to the crystal. A crystal containing donor impurities has a surplus of electrons and so is inherently negative in charge; it is called "N-type" germanium.

The substances with only three valence electrons are called "acceptor" materials because they "accept" only three electron-pair bonds and leave a "hole" which may be filled by any stray electron. This absence of enough electrons to fill all the possible bonds in the crystal results in a positive-charge characteristic, and such a crystal is called "P-type" germanium.

It's important to remember that the crystal *as a whole* is electrically balanced in either case, because the donor or acceptor atoms were electrically balanced before they became part of the crystal structure. The "positive" or "negative" imbalance we spoke of in the preceding two paragraphs refers only to "free" particles which are able to drift within the crystal. N-type crystals have electrons which are free to move without disturbing the crystal structure, while P-type crystals have "holes" which may be filled by electrons introduced from outside. Of course, whenever a hole is filled, the crystal itself has too many electrons for balance and must get rid of one, which produces a hole somewhere else, so that the original hole appears to drift through the material just as would the free electrons in N-type material.

Either P-type or N-type germanium is a better conductor than pure germanium would be, because the impurities provide either free electrons or free holes which can carry electric charge through the material. The free electrons or holes are called "charge carriers" or just "carriers" for short.

Now that we have seen how charge can move through the structure of a semiconductor crystal in the presence of impurities, we're ready to look at the reasons a semiconductor can work as it does. First, let's look at a diode.

If we take a crystal of N-type germanium and connect a battery in series with it, a current will flow. It is carried through the crystal by the free electrons in the crystal structure.

If we use a crystal of P-type germanium instead, the same thing will happen, with the holes carrying the current through.

If we disconnect the battery from both crystals, no current will flow. The atoms inside each crystal would be vibrating because of heat energy which is always present, and the carriers in each crystal would be "diffusing" at random throughout the structure, but nothing would escape from the edges of the crystal.

Now let's join these two separate crystals to form a single crystal, which is N-type at one end and P-type at the other end.

We might expect the holes in the P-type to move toward the junction, in their random diffusion, and there meet the electrons from the N-type, combine into a filled electron-pair bond, and thus eliminate all carriers from the crystal.

This process actually starts to happen

when we form such a crystal—but it stops itself soon after it starts, and long before all the carriers are eliminated from the crystal. When a hole from the P-type and a free electron from the N-type join to form a new electron-pair bond at the junction, this leaves a nucleus short one electron in the N-type material, and a nucleus with one electron too many in the P-type region. The charge across the junction is no longer balanced. The next free electron which diffuses toward the junction is repelled by the excess negative charge now present in the P region, and cannot get to the junction to join with a hole.

So long as any point exists at the junction where holes and electrons can meet without repulsion, they will do so—but as soon as every electron-pair bond across the junction has been filled, no more carriers can cross the junction because of the "barrier" established by charged nucleii just outside the junction area. This barrier area is known as the "depletion region" (Fig. 4) and also as the "space charge region." It has definite physical width.

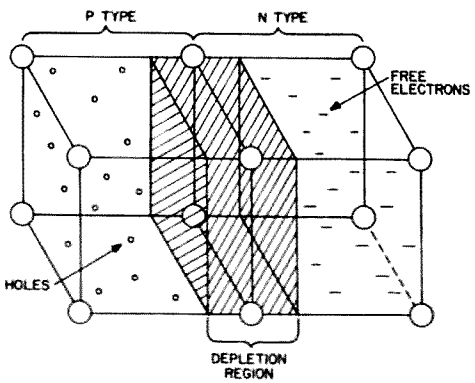

Fig. 4. When P-type and N-type material are joined into a single crystal structure, holes and electrons recombine at the junction to form a barrier or depletion region, shown shaded here. Holes are concentrated at P-type side of barrier and free electrons are at N-type side. Crystal as a whole is electrically neutral, however.

The unbalanced nucleii which establish the barrier are (or may be considered to be, which amounts to the same thing) near the outer edges of the depletion region; since all the electron-pair bonds within the depletion region are filled, this area acts as an insulator—and we have, in effect, a charged capacitor *inside* the crystal.

One way of defining voltage is in terms of the amount of charge in a capacitor. Normally, this is a sort of "reverse English" manner of defining voltage—but in this specific case it lets us think of the barrier in terms of voltage, and this equivalent voltage defined by the charge surrounding the depletion region is known as the "height" of the barrier.

For any particular junction, the height of the barrier depends upon many things. Some of these things are the amount of impurities present in the crystal structure, the temperature (which determines how much bouncing about inside the crystal the carriers may do), and the amount of light reaching the crystal (which provides energy, just as does heat). The most important, though, is the material of which the crystal is made. The barrier in any germanium crystal junction runs between 0.2 and 0.3 v in height, while that in a silicon junction runs between 0.6 and 0.7 v height, in the absence of any external forces.

It's important to remember that the barrier comes into existence when the junction between N-type and P-type material is formed in a single crystal. It's always there. Whenever we have a junction, we have at the junction a depletion region and a barrier. The barrier height depends upon the crystal, but is somewhere around half a volt in most cases in the absence of external forces. Now let's see what happens when we connect *this* crystal to a battery.

Let's try it first with the positive pole of the battery hooked up to the N-type end of the crystal. The battery provides electrons at its negative terminal and forces them into the P-type end of the crystal. This fills even more holes in the P-type material, while the positive terminal of the battery is drawing electrons out of the N-type end of the crystal and so is taking out even more free electrons than were already used to form the depletion region.

As free electrons are drawn out of the crystal toward the positive pole of the battery, the random diffusion within the N-type material tends to move them away from the barrier to fill the gaps. Similarly, the holes in the P-type material move away from the barrier to replace the holes filled by electrons from the battery. The net result

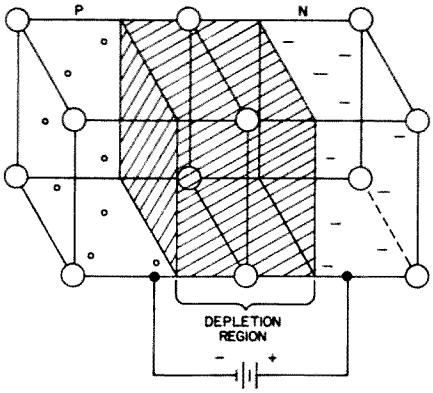

Fig. 5. Battery connected as shown here supplies more electrons to fill holes in P-type end of crystal, and withdraws free electrons from N-type material. Result is widening of depletion region until voltage across barrier equals voltage of battery, or until crystal structure breaks down if voltage is too great. Condition is known as "reverse bias."

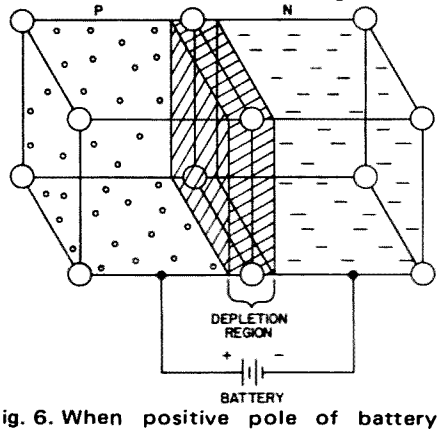
is that the depletion region becomes physically wider—and the barrier becomes higher. This process continues until the height of the barrier exactly equals the voltage of our battery. When this occurs, no current can flow, because the voltage of the battery is exactly balanced out by the height of the barrier at the junction.

Under these conditions (Fig. 5), our junction is an insulator.

If we reverse the connections to the battery, though, things change. Now, every time a free electron and a hole combine at the junction, they are replaced by a new electron put into the N-type end of the crystal from the negative pole of the battery and a hole created in the P-type material by the battery's taking away an electron. This *reduces* the width of the depletion region



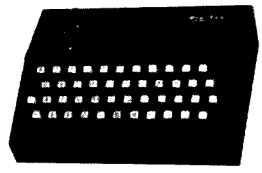


Fig. 6. When positive pole of battery is connected to P-type end of crystal, battery supplies free electrons to N-type and draws electrons out of P-type to produce more holes. This narrows the depletion region and reduces resistance of crystal structure.

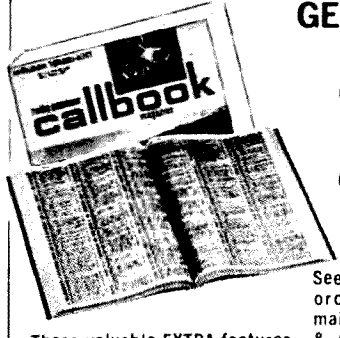
Pro-key Kit

Send perfect morse code – from 5 to 50 words per minute. Excellent to build up your code speed – anyone can send practice code.



- Self-completing characters with automatic character spacing.
- Precision kit includes all parts, such as metal case and printed circuit boards, and detailed, illustrated instructions.
- Pre-assembled keyboard with standard typewriter key arrangement and spacing.
- Special characters included, such as AR, SK, BT, period, comma, question mark, slant bar.
- Self-contained battery operated – two standard "D" cells. All solid state.
- Built-in sidetone and speaker, fast acting relay output.

(Fig. 6) and the height of the barrier. It does even more—when the barrier is completely overcome, it makes the crystal into an excellent conductor.

The junction, then, is effectively a polarity-sensitive switch. For current flow in one direction, it is an open circuit, but if current attempts to flow in the reverse direction it turns into a conductor.

Such a device is, by definition, a diode and a rectifier. If we apply ac, instead of using our dc battery, the polarity will reverse every half-cycle. Those half-cycles which oppose the barrier are blocked, but those which reduce the depletion region width go through unchallenged—and the output is pulsating dc.

We call the open-circuit condition "reverse bias" and the closed-circuit condition "forward bias," the "voltage drop" of a junction diode is simply the barrier height, because even in the forward-bias condition the applied voltage must overcome the barrier before the depletion region's width drops to zero and closes the switch.

It is possible to force current through a reverse-biased junction diode; if the applied external voltage is so great that the entire crystal is used by the depletion region, for instance, any increase in voltage cannot be overcome by additional expansion of the depletion region. In such a case, the crystal structure actually breaks down and current flows unchecked. If the current is limited by something outside the crystal so that excessive heat cannot be generated, the breakdown heals automatically when the overvoltage is removed; if nothing limits the current, the crystal material is usually vaporized by excessive heat. Zener diodes make use of this reverse breakdown, but in most cases it's something to avoid; that's why diodes are rated for "peak inverse voltage" or "PIV"—that's all they will stand in reverse!

Most rectifier diodes now in use are of silicon rather than germanium, but they work in just the same way. The reason silicon is used is that it is much less temperature-sensitive than germanium, and has higher resistance when reverse-biased. The reverse resistance of a good silicon diode may be greater than 10 megohms, while the resistance in the forward direction is usually less than 500 ohms.

A part of the voltage drop associated with a silicon diode is simply the result of Ohm's Law, because of the 500-ohm forward resistance. However, the forward resistance varies with the amount of current flowing, so that the voltage drop is hardly ever more than a volt (the barrier in most silicon rectifier diodes averages 0.65 volts without current flowing). In fact, it's necessary to put current-limiting resistors in series with silicon diodes to keep them from destroying themselves in normal operation, because they will permit extreme current flow in the forward direction. These resistors are usually 47 ohm 1/2-watt units, which serve the purpose adequately in most cases.

The action of the silicon is a direct result of the crystal structure including the junction between P-type and N-type silicon. This is different from a vacuum diode, which boils electrons off a heated cathode and permits them to flow to the plate whenever the plate is more positive than the cathode. The major differences which result from the different action are:

1. The vacuum diode requires power to heat the cathode while the silicon diode does not.

2. The vacuum diode requires an envelope to maintain its vacuum; the silicon diode is a single crystal and can be quite small.

3. More force (external voltage) must be applied to move electrons across the distance between cathode and plate in a vacuum diode than is necessary to move charge across the junction in a semiconductor, because of the 10-million-to-one variation in the distance (atomic in the case of the junction, easily visible in the vacuum diode).

4. The heater in the vacuum diode eventually burns out; the semiconductor diode has no known failure mechanisms which are inherent in the unit itself, and most failures are caused by failures of other items in the circuit. No semiconductor has ever been known to "wear out" with use.

Most of these differences are also applicable when comparing vacuum tube amplifiers to transistors—but that's our next subject. At this point, we have a fair (although incomplete) idea of what a semi-

conductor is and why it can act as it does, and it's time to move on to study the transistor.

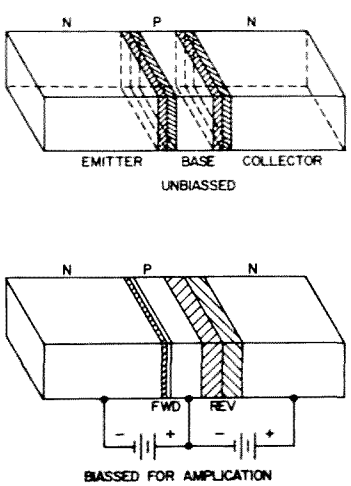
How Do Transistors Amplify?

We have just seen how the polarity of voltage applied to a single semiconductor junction between P-type and N-type semiconductor material controls the width of the depletion region which exists at the junction, and so controls the resistance of the junction. This is enough to give us diode action, but something more is necessary in order to get amplification.

Let's sandwich a slice of P-type material between two pieces of N-type material in a single crystal and see what happens. Each N-P junction is immediately surrounded by a depletion region; since we have two N-P junctions, one on each side of the P-type region in the crystal, we have two depletion regions.

Either of these junctions alone will act just as does the single junction of a diode. For instance, if we forward-bias the leftmost junction in Fig. 7 and leave the right-hand junction disconnected, the depletion region becomes narrower. If we apply reverse bias, the depletion region widens.

But since both junctions are in a single crystal structure, something more complicated happens if we apply bias voltages to both. If the thickness of the P-type portion



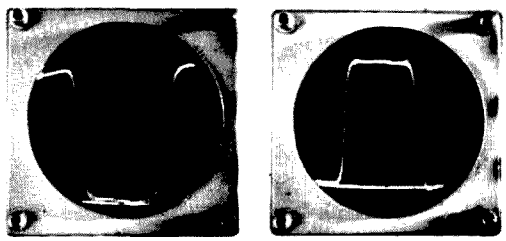


Fig. 7. Placing two junctions in a single crystal structure produces two barriers and two depletion regions, as shown at top. When bias voltage is applied as in bottom view, one junction is forward biased with small depletion region and other is reverse biased with large depletion. This makes amplification possible.

of the crystal is small enough, and we forward-bias the one of the two N-P junction, many of the electrons which go into the N-type material shoot right on through the P-type region without meeting any holes, picking up enough energy on the way that they shoot right through the barrier of the other junction into the other N-type region. There, they may meet holes—or, if polarities are correct, may flow right on out into an external circuit.

In order for these shot-through electrons to be able to continue into an external circuit, the right-hand N-type material must be connected to a more positive voltage than is the P-type material in the center. This, however, amounts to reverse bias on the right-hand P-N junction.

And as we saw when examining action of a single junction, a reverse-biased junction has extremely high resistance.

The left-hand junction, being forward biased, shows a very low resistance. Yet it is the electrons injected into this low-resistance circuit which shoot through and affect the current flow in the high-resistance reverse-biased circuit. This is a *transfer* of signal from a low-resistance to a high-resistance circuit, with very little loss of current, and such a transfer amounts to a power gain (1 mA in a 10-ohm circuit is 10 microwatts; the same 1 mA in a 10,000-ohm circuit is 10,000 microwatts, or 1000 times more power).

This is, about as precisely as we can put it without resorting to pages of higher math, just how a transistor operates. What we see in **Fig. 7** is an NPN transistor; the N-type material at the left is the emitter, the P-type region in the center the base, and the N-type material at right is the collector.

The names applied to the elements of the transistor may make a little more sense now. The emitter emits electrons, under the influence of the forward bias between itself and the base. Actually, the electrons are pushed out by the battery which establishes the forward bias. They shoot right through the base region into the collector, which collects them.

The amplification comes about because the emitter-base circuit is at low impedance while the base-collector circuit is at high impedance, and the flow of electrons all the way through from emitter to collector is a series circuit in which constant current flows.

Not all the electrons make it through the base region, of course. A few of them must recombine with holes in the base, to maintain a current flow in the base circuit and keep the emitter-base junction forward biased. Almost any transistor, though, will let at least 95 percent of the electrons which leave the emitter reach the collector. High-gain transistors permit only a very small fraction of one percent of the emitted electrons to be trapped by the base.

In the early days, a factor called "alpha" was used to rate the gain of transistors, and it was, specifically, the ratio between the number of electrons reaching the collector and those which left the emitter.

It wasn't measured by counting electrons directly, of course. Instead, current in the emitter circuit and current in the base circuit were measured and compared. An alpha of 0.99 meant that for every 100 mA in emitter circuit, 1 mA flowed in the base circuit and the remaining 99 went on through to the collector circuit. Alpha always ranged between 0 and 1; a very high gain unit might reach 0.9999999999, but it could never quite get to 1.0 because if it did, no current would be left to flow in the base and keep the transfer action going.

Partly because of this bit of mathematical confusion, and more because of a change in the preferred type of circuits as designers gained experience with the transistor, a different rating called "beta" by most and "H_{fe}" by some came into widespread use, and today most gain comparisons are made on the basis of beta rather than alpha.

The beta of a transistor is the ratio between the current flowing in the base circuit and that flowing in the collector circuit. Our preceding example, for instance, with 1 mA in the base and 99 mA in the collector, would result in a beta of 99.

Beta and alpha are mathematically related by the fact that all the current reaching either the base or the collector normally goes through the emitter; if you know alpha and need beta, simply divide the alpha figure by the difference between 1 and alpha (to apply this to our example, 0.99/(1-0.99) or

0.99/0.01) and the result is beta.

Actually, a small amount of leakage current may flow, so that these and other mathematically based relations do not always hold true in practice—but they're usually plenty close enough for our purposes.

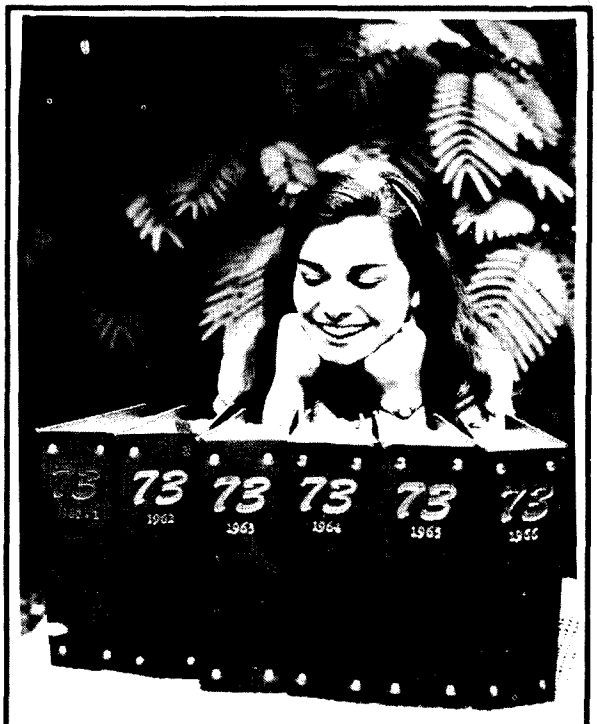
The NPN transistor we have just looked at operated with polarities very similar to those of vacuum tubes, except that the base (which corresponds to the grid of the tube) is positive rather than negative with respect to the emitter (which corresponds to the tube's cathode).

Transistors differ from tubes in one major respect, however. Tubes can only employ electrons as their carriers, because holes cannot exist in a vacuum (they are an inherent part of crystal structure and cannot exist outside that structure). Since the transistor uses crystal structure to achieve its effects, it can just as easily sandwich a slab of N-type material as a base between two slices of P-type, and we then have a PNP unit instead of NPN.

The PNP unit operates exactly as does the NPN, except that holes replace the electrons as the charge carriers, and all the bias-voltage polarities must be reversed.

The existence of both NPN and PNP transistors makes many circuits possible which cannot be done with tubes. For example, a single-ended input signal can drive a push-pull amplifier direct without any need for phase inverters or center-tapped driving transformers, if one half of the push-pull stage used an NPN transistor and the other half is PNP (providing that bias is properly set).

When we compared junction diodes and vacuum diodes, we found a number of differences which also apply to a comparison of transistors and triode vacuum tubes. Here are a few more:



1. The main current flow in a vacuum tube is from cathode to plate; in an NPN transistor, the main current flow is from emitter to collector. In the tube, the current passes through the grid; in the transistor, it passes through the base. Thus the emitter of the transistor corresponds to the cathode of the tube, the base to the grid, and the collector to the plate (Fig. 8).

2. In most applications of tubes, no

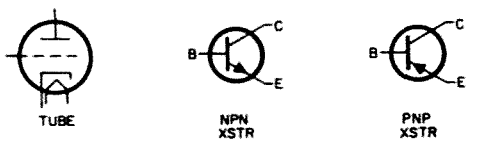

Fig. 8. Schematic symbols for both NPN and PNP transistors as compared with symbol for triode tube. Type of transistor is indicated by direction of arrowhead on emitter lead; the arrowhead points in the direction of positive current flow. Symbol corresponds closely to that for semiconductor diode, in which arrowhead also points in direction of positive current flow (as opposed to negative electron flow).

current flows in the grid-cathode circuit, so that the grid of the tube is a very high impedance. In most transistor applications, the base-emitter junction must be forward-biased and current flows; the circuit is a low impedance. Thus the input resistance of the tube is usually much higher than that of a transistor.

Since the emitter, base, and collector of the transistor do correspond to the cathode, grid, and plate of the triode tube, transistors can be hooked up as amplifiers in circuits (Fig. 9) which correspond to the three types of vacuum-tube amplifiers: conventional grounded-cathode, grounded-grid, and cathode follower.

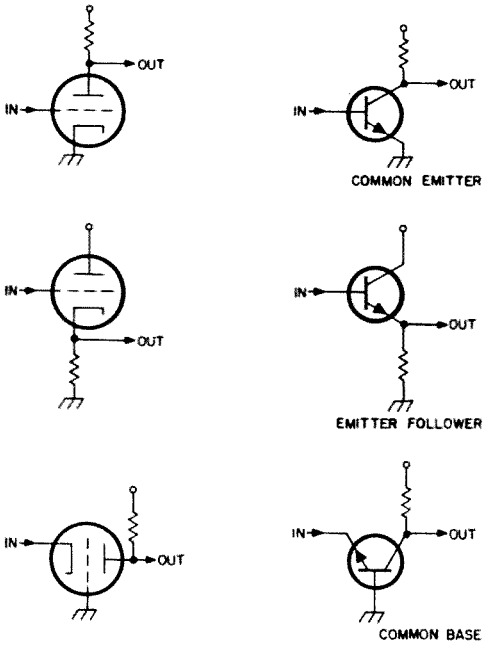

Fig. 9. The three basic types of transistor amplifier circuits are shown here as compared to the corresponding vacuum-tube circuits. Only signal paths are shown; each transistor circuit requires bias arrangements also as shown in Fig. 10 for the common-emitter case.

The corresponding transistor amplifier circuits are known as the common-emitter, common-base, and emitter follower or common-collector. The common-emitter circuit is most frequently employed now, and corresponds to the grounded-cathode tube circuit. The emitter follower or common-collector circuit is frequently used to increase input resistance of transistor circuits.

Characteristics of each of these transistor circuits are roughly similar to those of the corresponding tube circuit, keeping in mind the inherent lower input resistance of transistors.

Like the grounded-cathode tube circuit, the common-emitter transistor amplifier offers moderate input resistance and reverses the phase of the signal between input and output.

The emitter-follower, like the cathode follower, has high input resistance and a voltage gain of less than one. Phase of the output signal is the same as that of the input.

Any transistor circuit, whether common-emitter, common-base, or common-collector, must be biased properly in order to amplify. The bias voltages establish the required reverse bias of the collector-base junction and forward bias of the base-emitter junction. The collector bias voltage corresponds directly to the B+ or plate supply voltage of the vacuum-tube circuit, but the base bias voltage differs from the grid bias of a vacuum tube because current normally is allowed to flow in the transistor's base circuit.

For proper amplification, base bias is somewhat critical—but no more so than is the grid bias of a tube. If too much current is permitted to flow in the base circuit, the transistor will act as a switch rather than an amplifier; if insufficient current flows, the transistor will be cut off (little or no collector current). The overbiased condition is known as "saturation," and the underbiased conditions as "cutoff." For proper amplification in most circuits, bias should be adjusted to a value halfway between cutoff and saturation; this will permit the largest possible input signal swing between these limits.

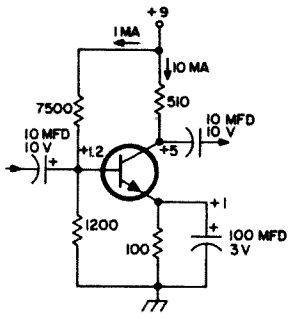

Fig. 10. Emitter bias circuit as applied to a common-emitter audio amplifier circuit using an NPN transistor. Emitter resistor's value is chosen to give a convenient amount of voltage drop when desired emitter current flows, and voltage divider supplying bias to base is then set to provide this same voltage plus barrier offset (about 0.2 volt for germanium transistors or 0.6 volt for silicon). Emitter current will stabilize at desired value. Change in supply voltage requires only changing of base voltage divider to keep base voltage constant.

In a vacuum tube, amplification can be controlled by varying the grid bias. Changing the base bias of a transistor has much less effect upon the amplification, although a limited control is possible by this means.

Bias can be supplied from separate supplies, but it's more common to use a resistive voltage divider to put the base at some voltage between the collector-supply level and ground, and include a moderately small resistor in the emitter circuit as shown in **Fig. 10**. This corresponds to the "cathode bias" arrangement used frequently in tube circuits; it makes the bias automatically self-compensating to just that amount which will permit a desired level of emitter current to flow. While **Fig. 10** show this in a common-emitter circuit, the same bias arrangement can be used for any of the three types of circuits by moving the ac grounds and signal input/output points while leaving the dc portions of the circuit unchanged.

What Factors Affect a Transistor's Amplification?

Now that we've met the transistor as an amplifier, it's time to take a deeper look at the factors which affect the transistor's performance in this role.

Among these factors are the signal frequency, the construction of the transistor, the circuit constants, and many others. Let's look at the transistor's construction first, because in practice we have no control over this except to choose a particular type of transistor which has the type of construction we desire.

The transistor which we used as an example (**Fig. 7**) was a single crystal of semiconductor material with the base sandwiched between the emitter and collector. We drew it in the shape of a long narrow slab to make the explanation easier to follow visually—but very few actual transistors use this shape. In practice, the designer of a transistor must juggle such factors as the width of the base region, the capacitance across each junction, the thickness and volume of the collector (which sets the power rating of the unit), and the area of the emitter junction. Most of today's common transistors, as a result, resemble tiny ham sandwiches; they are spread out over a wide area but are not very thick. The collector is the largest part, with the base on top of that and the emitter covering the base; both emitter and base are normally very thin.

The width of the base sets a limit on signal frequency, because any carriers which remain in the base region for an appreciable fraction of a signal cycle cannot be controlled by the signal (it will be pulling them part of the time and pushing them the rest of the time). Early transistors were limited to audio frequencies because of this, but modern units are capable of amplifying well into the rf range and many "ordinary" transistors operate nicely up to 5 or 10 mhz. For higher frequencies, different construction techniques are used; transistors which operate in the ghz frequency range are available although expensive.

Base width also determines to some degree the amplification ability of the transistor; a thick base can capture more carriers than can a thin one, which means that fewer carriers will go on through to the collector. This increases the base-current/collector current ratio, which reduces both alpha and beta.

Circuit constants affect transistor amplification in the same manner as they affect tube amplification; a high value of load resistor will give increased voltage gain, if

enough current can be made to flow through it. Increased forward bias will permit greater current flow. However, each type of transistor has an optimum operating point which provides maximum amplification consistent with linearity. You can get higher gain, but at the cost of possible distortion.

Is Amplification All?

The most familiar use of transistors, to most of us, is in amplifiers or amplifier-related circuits such as oscillators or active filters. However, as we've already glimpsed, the transistor also has the capability of acting as a switch if the base bias is varied between saturation and cutoff—and in fact, the most common use of transistors today is not in amplifiers at all, but as the switching element in digital computers.

A switching transistor and an amplifier transistor are essentially the same, except that the switching unit is designed to emphasize its switching properties and is not tested for use as an amplifier. Despite this, most switching transistors make highly acceptable amplifiers if you're willing to develop your own circuit constants for them.

When a transistor is saturated, that is, when so much base current is supplied that no additional change of collector-emitter resistance can occur, it is a better switch than many mechanical switches. The voltage drop from collector to emitter under these conditions is usually much less than 0.1 volt (as compared to the 0.25-volt drop between base and emitter at the same time).

In cutoff, however, almost no current flows through a silicon transistor, and very little through a good germanium unit.

By removing the base-bias network from a common-emitter amplifier circuit and bringing the base lead out (through a current-limiting resistor) as the input terminal, we have the basic transistor switching circuit shown in **Fig. 11**. If voltage is applied to the input with a polarity that provides forward bias to the base-emitter junction, current can flow in the load circuit. In the absence of input voltage, or with reverse-bias polarity, current flow in the load circuit stops.

Placing a resistor in the load circuit, and then connecting two such switching circuits back to back as in **Fig. 12**, gives us a

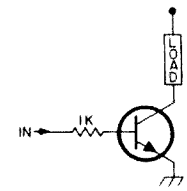

Fig. 11. Basic transistor switch circuit is simplicity itself. Transistor is connected in series with the load to be switched, and control voltage is applied through a resistor to the base, to assure cutoff in the absence of control voltage input, but in many cases the zero-bias leakage current is small enough that no more components than shown here are necessary.

"memory" circuit. If we ground terminal 1, this will cut off transistor Q1 and halt the flow of current through R1. With no current flowing through R1, the collector of Q1 will rise toward the supply-voltage level. This provides forward bias to Q2, driving it toward saturation and permitting current flow through R2. When Q2 saturates, the voltage at its collector is virtually ground level and we can now remove the ground from terminal 1 because Q2 has turned into a permanent ground at the same point in the circuit.

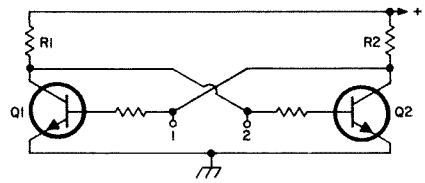

Fig. 12. Two simple transistor switches (Fig. 11) with resistors for loads, and cross-coupled to each other back to back, form a simple memory circuit which is actually used in some digital computer designs, and which is the heart of most of the more complicated flip-flop circuits. This version is known to computer designers as the "DTL flip-flop" (direct transistor logic). Operation is explained in the text.

This circuit will "remember" that condition until we ground terminal 2, no matter how long we wait. When we ground terminal 2, we remove the voltage from the base of Q2 and thus cut it off. The voltage at Q2's collector rises, driving Q1 into saturation. When Q1 saturates, it holds Q2 cut off. The circuit is now remembering a new condition.

This circuit, called a "flip-flop" by most computermen in this country and known to engineers as a bistable multivibrator, is the heart of most computers. In practice, more elements are needed in order to speed up

action, etc.—but the simple sample circuit here will work as described.

While the transistor's use as a switch is its most common application, and its use as an amplifier is the most familiar to most of us, there are still other uses.

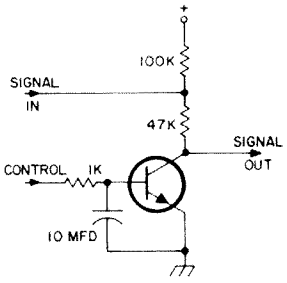
One of the more interesting is its use as a current-controlled resistor.

Both amplification and switching action in the transistor come about, as we have seen, by a change in the resistance of the collector-to-emitter circuit caused by a change in the current flow in the base-emitter circuit. We can, then, simply use the collector-to-emitter circuit as a variable resistor, and change its resistance by changing the current flow in the base circuit.

This offers, as one example, a simple automatic gain control technique. The agc control voltage is converted to current by a series resistance and applied to the base of a transistor; the transistor is in series with a fixed resistor which forms a voltage divider for the signal being controlled.

If control voltage and consequent base current are high, the transistor's resistance is low and the voltage divider has low output. If control voltage and base current are low, the transistor's resistance is high and the voltage divider has little effect.

The circuit, diagrammed in **Fig. 13**, can be applied to many other uses. It has been used, for instance, as a motor speed control—but in such a use the transistor must



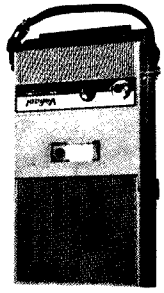


Fig. 13. Transistor may be used as current-controlled variable resistor to provide AGC circuit as shown here. Application of positive control current or voltage reduces collector-emitter resistance of transistor, reducing output voltage. Reduction of control current increases transistor resistance, raising output voltage. Topmost resistor is to isolate signal from low impedance of power supply. Values are only suggested; in any specific application they would have to be tailored to the needs of the circuit.

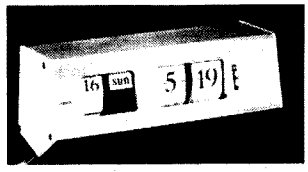
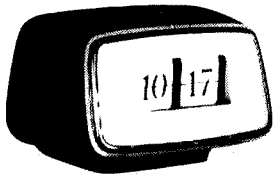


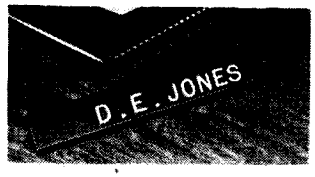
SHOP-BY-MAIL SPECIAL VALUES!

CASSETTE TAPE RECORDER



REDLINE presents the Valiant. This neat little cassette tape recorder has excellent fidelity and an easy push button system that means everyone in the family can use it and have fun. It has a battery level meter, recording level meter, a jack for feeding hi-fi or your receiver (or tv), and operates from a switch on the mike. Record those rare DX contacts as well as your regular friends off the air. The price is ridiculously low. SPECIAL, ONLY $33.00 postpaid.

24 HOUR CALENDAR CLOCK



Your operating desk will stand out with this day-date clock. Great for the office too. Set the 24-hour model on GMT and never make a time or date mistake again. 8" x 3½" brushed aluminum case, self-starting, 110 v 60 cy. Please specify 12 or 24 hour clock. SPECIAL Calendar Clock ONLY $40.00 postpaid.

24 HOUR DESK CLOCK

This clock can be read from 15 feet in a dense fog. Available in charcoal gray, coral red, light blue, white or brown. Please specify 12 or 24 hour clock. They are beautiful. ONLY $24.95 postpaid.

DESK NAME PLATE

We sold a boodle of these at the last big hamfest. You can order your name and call on this handsome desk plate in up to 20 letters and spaces. Immediate delivery on all orders, too. The plates are brown walnut stained and a real value at only $2.00 pp.

Send order to:
REDLINE Co. Box 431, Jaffrey NH 03452

Tape recorder — 24 hour calendar clock

dissipate large amounts of power (in the agc application, almost no power is involved).

What About the Rest of the Family?

We've examined junction diodes and junction transistors, both silicon and germanium types. We have by no means seen all the semiconductor family. We have completely skipped over the point-contact diodes and transistors, partially because they are little used today but primarily because modern theory indicates that they are actually junction devices in which the junctions are created at the points of contact during use (which means that they operate in essentially the same manner).

Some of the other semiconductor devices operate in totally different fashion although based on the same basic events in a crystal structure, and some bear the same relation to transistors that transistors bear to diodes—an apparent combination, modified by the fact that the whole combination is in a single crystal.

The silicon controlled rectifier (SCR) is one of these combination devices. It can be simulated by a hookup of PNP and NPN transistors as shown in Fig. 14—but only if both transistors have essentially zero leakage current. It is a switching device only; when "off," almost no current flows through, and when triggered "on" by a small signal in the gate circuit, a large flow of current can flow with no more voltage drop than an ordinary silicon diode.

Fig. 14 indicates that such a device should be able to be turned either "on" or "off" by control signals; most SCR's only turn "on" by control signals, and must be turned "off" by other means. A similar device based on the same principles, known as the silicon controlled switch (SCS), has both "on" and "off" capabilities.

The four-layer diode is similar in characteristics to the SCR but has only two terminals; the "turn-on" signal is generated inside the crystal structure by the applied voltage. The result is that the device is an open circuit for voltages below a critical "threshold" value, and a closed circuit for voltages above that value.

The unijunction transistor, originally called the double-base diode, is a completely different device. It has only one junction, and injection of current into this junction affects the current flow through the main mass of semiconductor material. This device does not amplify, but is excellent as a switch in timing circuits similar to neon-bulb oscillators.

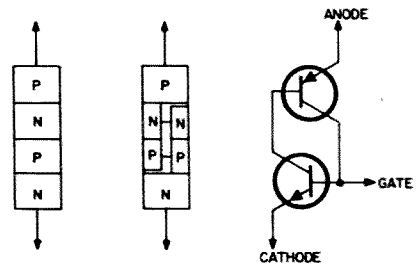

Fig. 14. Actual structure of SCR is four-layer PNPN sandwich as shown at left, but operation is very similar to that of two perfect transistors as shown in center, hooked up as shown in schematic at right. If both transistors have almost zero leakage, circuit at right will work; in SCR, leakage is held to minimum by action within the crystal structure.

The field-effect transistor is something of a cross between the ordinary transistor and the unijunction. Fig. 15 shows how it works in principle. Only one junction is involved, and it is always reverse-biased. The amount of reverse bias varies the depth of the depletion region in the main mass of the material, which varies the resistance between the source and drain terminals. The FET has operating characteristics very similar to those of a vacuum tube—input resistance is high and no current flows in the input circuit.

Voltage-variable capacitors and varactors are simply specially processed junction diodes, making use of the variation of the depletion region thickness with variation in

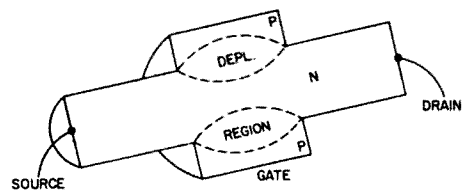

Fig. 15. Cutaway view of theoretical field-effect transistor shows how depletion region created by reverse bias of the gate material (in this example, a ring junction all the way around the main semiconductor) "pinches" down the available current path and so increases the device's source-drain resistance. Actual FET's are considerably more complex than this simple model.

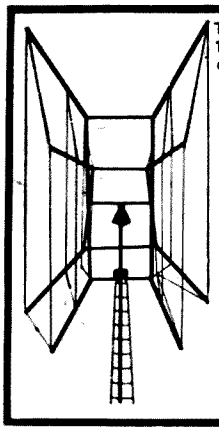
bias voltage to change capacitance across the junction.

Zener diodes and tunnel diodes are also specially processed junction diodes. A zener diode is built to maintain a constant breakdown voltage in the reverse-bias direction and serves the same function as a vr tube. A tunnel diode contains much higher levels of impurities and apparently operates in precisely zero time (the physics of it are still somewhat unclear to most students); the effective result is the establishment of theoretically impossible negative resistance, which in turn makes any resonant circuit capable of oscillation.

The "integrated circuit" is today's frontier of semiconductor study; any one integrated circuit contains transistors, diodes, resistors, capacitors, and conductors, all of which may be grown into a single crystal structure. When each individual component of an IC is examined by itself, it is found to be identical to that same component in any other application—the IC is more a means of packaging complete circuits in very small spaces than it is a separate member of the semiconductor family.



This is not all the list by any means; semiconductor technology is moving so rapidly today that no list could ever be complete, because new types would be invented in the time between writing the list and its publication. However, these are most of the members of the family that you're likely to meet soon in the radio world—and this is enough of their basic theory to provide answers to all the semiconductor questions on the Extra Class examination.

A Preamplifier for the CB and Ten-Meter Bands

Mark Gutekunst WA3HMW
27 Rorer Avenue
Hatboro, PA 19040

Did you ever want to listen in on the CB or 10 meter bands and find your receiver sounded completely dead? Perhaps it is too noisy and the signals are there but you cannot hear them, or maybe it simply is not sensitive enough.

What you need is a high-frequency preamplifier, and a nice surplus item can be converted very easily to boost your receiver's performance.

The Conversion

Begin with a No. MFP-50 10 meter preamplifier. This comes unconverted at around $5 plus postage.

The conversion consists of installing two BNC connectors and appropriate power connections; adding a link input circuit, and tuning up. You may need to build a power supply. Here is the conversion process:

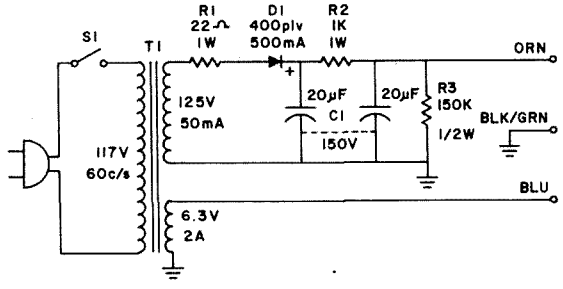

Fig. 1. Power supply circuit. Parts list: C1-dual—20μf, 150 volt electrolytic; D1—400 piv 500 ma silicon rectifier; R1—22ohm 1 watt resistor; R2—1000ohm 1 watt resistor; R3—150K ½watt resistor; S1—SPST toggle switch; T1—Power transformer, Allied 54C 1411, primer 117 volts ac, secondary 125 volts ac, 50ma, 6.3 volts ac 2 amps.

Step 1. Remove connector from 6 inch cable and add extension cable or other provision for connections to power supply. Connections are: Black, chassis ground. Blue, 6.3 volts at 0.45 amps heater ac. Orange, 120 volts dc screen and anode supply, about 30 ma. Green, chassis ground. Brown, not used.

Step 2. Replace black bakelite plug under the chassis with a BNC connector, and label this "Input." Remove coil form L1301.

Step 3. Wind 6-8 turns of No. 20 enameled wire around coil T1302, grounding one end and connecting the other to the BNC connector previously installed.

Step 4. Replace connector J1301 with a BNC connector, and label this "Output."

Step 5. Remove the two pi-wound chokes, one at each end of the chassis along with the red wire that connects the two chokes.

Step 6. Complete the power connections and install the preamplifier in your receiver's antenna circuit. Turn it on, let it warm up, and then peak TI301 and TI302 in the center of the 10 meter band. You may need to use solvent to soften the cement holding the slugs in place, or you will chew up the slot on the coil slug.

Results

This preamplifier should make any surplus or cheap ham receiver come alive on 10 meters. It is quite broadbanded, shows a possible 30 dB gain, and has a very low noise figure. Any questions will be answered if an S.A.S.E. is enclosed. Gud Luck!

Proper Use of Silicon Rectifier Diodes

R. T. Brackman WA3ACL
Physics Dept.
University of Pittsburg
and
M. Weinschenker K3DPJ
Box 353
Irwin PA

One or two of these tiny components, closely resembling resistors, can do the same job as a large vacuum tube of not too many years ago. They cost less than the tubes, and are more effective. But if abused they can depreciate to zero value in part of a millisecond. What are they?

They are silicon diodes, available on the commercial or surplus markets at very economical prices. Their basic electrical property is very simple: in the forward direction they will pass up to several amperes (for a small silicon diode) at a constant voltage drop under 1 volt. And in the reverse direction they will pass a tiny current. The details of these properties are different for various types and for individual specimens of a given type of diode. Rectifier diode failures in practical applications are directly associated with these two properties of forward conduction and reverse resistance.

The Forward Current Rating

When a diode is in forward conduction, which normally is during the part of each half-cycle when the voltage applied to the diode exceeds the voltage appearing across the filter input terminals, the combined voltage across the diode and the current through it indicate a certain amount of heat energy is released in the diode. In normal operation the diode gets warm.

If the current becomes large enough, the diode may be heated to a point at which it is either unable to resist the reverse voltage appearing during nonconducting parts of its operating cycle, or to a point at which the semiconductor doping atoms begin to migrate to new sites. Either condition is likely to prove fatal, since a breakdown condition or doping atom migration increases diode temperature and resistance.

Once the failure process starts, it develops regeneratively to a catastrophic end. This is why manufacturers are very specific about forward surge and inverse specifications. A key point in forward rating specs is that the diode does have a certain internal resistance, and heat dissipated in this resistance increases as the square of the current. Surges, such as tend to occur when turning on a capacitor-input supply, immediately after an accidental short, or during sideband or photoflash operation, may destroy diodes. See Fig. 1. If your power supply consumes diodes at an unreasonable rate, this possibility deserves investigation.

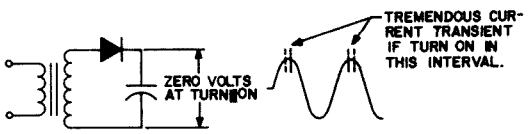

Fig. 1. If a power supply is turned on at the instant the supply voltage is at its peak, the transformer sees a short-circuit and may be required to deliver tremendous amperages through the rectifier diode circuit.

PIV Rating

When a diode fails, the typical conclusion is that its PIV has been exceeded. This conclusion *may* be correct. If the diode's forward current ratings have been given due respect, the possibility of inadequate PIV rating becomes quite likely.

There is an instant during each operating cycle when, if there is any kind of filter, the filter voltage and the applied ac voltage combine to apply a maximum reverse-

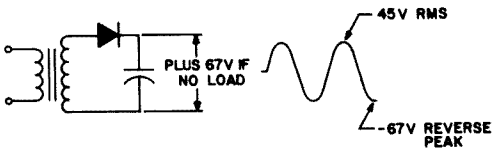

Fig. 2. There is an instant during each cycle in normal supply operation when the diode is facing into full capacitor voltage, with the transformer in back of it exerting an opposite voltage. This is the instant when diode failure from PIV stress is most likely.

voltage stress to the diode. See Fig. 2. If the diode is unable to resist the stress it goes into conduction. This is not necessarily fatal, and zeners normally operate in a breakdown mode.

But since there is plenty of power available from the transformer and stored in the filter, a large reverse current flows. The diode becomes very hot, doping atoms migrate, and the junction loses its rectifying properties. It conducts about as well as a piece of wire in either direction. It has failed.

Manufacturer's PIV ratings tend to be realistic, and the ratings of surplus diodes may be optimistic. That is, these ratings are exceeded only with expectations the diode may fail any cycle now – and at 60 hz the failure is generally not very far off.

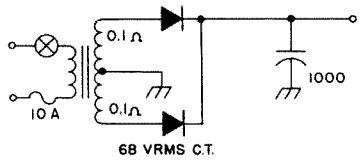

Fig. 3. Real transformers typically have low secondary resistances, if they are high-current transformers, or designed to deliver large amounts of power. This simple circuit will generate current surges on turn on in the hundreds-of-amperes range.

Practical Applications

In Fig 3. is shown a simple power supply for 48V with a large filter capacitor. After several days of operation, it fails. Why is this?

Looking at the schematic, perhaps you think of forward-current overload. This possibility deserves attention, since nothing in the schematic seems provided to limit the forward current upon turn-on, and the fuse is very large. But could the forward current ever be disastrously high?

Suppose the supply is turned on just at the instant the transformer secondary voltage swing is at its peak. At this time the emf is around 75 volts, and it will feed into an empty filter capacitor. This is a short, for practical purposes.

Circuit resistance being around 0.1 ohm here, a surge current of 750 *amperes* might be expected. That's why the primary fuse is so large! A scope test would show real surges of only a few hundreds of amps since the real transformer probably cannot deliver really heavy surges. But it *can* blow 1-amp fuses, and that's what the schematic specifies.

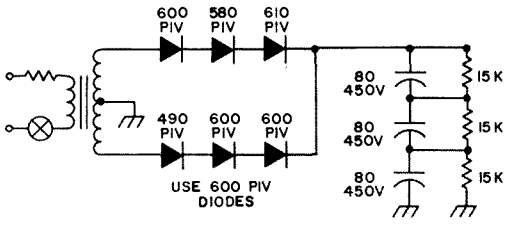
One answer to this problem is a series surge resistor, which is shorted during normal circuit operation. A 1-ohm resistor pares these surges down to 75 amps maximum, and if regulation is not too important, the shorting provision may be omitted. Another answer is a thermistor, which offers a relatively high cold resistance, but as it becomes warm its resistance drops to a low value.

Now let's examine the string of diodes appearing in Fig. 4. These diodes are healthy and the supply has been turned on without any harm because you have carefully provided a primary resistor to limit the turn-on current surge. When the voltage across the filter capacitors reaches about two-thirds of full value, a relay shorts the limiting resistor for normal operation. Now, having finished your work, you turn off the supply.

But you notice it makes a rather heavy "thunk!" Feeling suspicious, you turn it back on again, and within seconds the limiting resistor is emitting clouds of smoke. The fuse blows. What went wrong?

Looking at Fig. 4, we observe the diodes do not all have the same PIV ratings. Here we have the measured, not the advertised, breakdown voltages. At the moment we turned off the supply, the turn-off transient overvolted the string, and pushed the other string into conduction. Otherwise it would have been a much larger transient, suggesting to us that half-wave rectifier diode strings must be more conservatively designed than full-wave systems.

When the string was overvolted, one or two of its diodes went into reverse conduction, increasing the stress on the remaining diodes. They collapsed like a row of dominoes. The initial breakdown was followed by a powerful reverse current surge as the filter capacitor discharged back through the transformer, producing that "thunk" you noticed. Possibly the surge overvolted the other diode string, and that failed too.



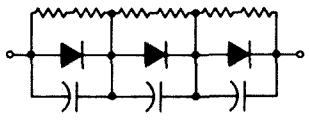


Fig. 4. This circuit may not show very good diode life. Diode PIV s shown are measured; the nominal specification is given in the corner of the drawing, and would be used in ordering diodes.

To avoid this accident, replace the original string with a more conservative arrangement as shown in Fig.5. The sum of all the PIVs might be twice the estimated maximum inverse voltage the circuit can generate, and a factor of 2.5 is good practice.

RESISTORS 47K 1W
CAPACITORS .005 M 1KV
DIODES 800 PIV

NOTE: 1W RESISTORS ARE RELIABLE AT 300V, USE TWO IN SERIES.

Fig. 5. Revised diode string for improved reliability. The PIV spec has been increased from 600 to 800 volts, and an RC network added to equalize DC and transient voltage stress along the string. Note the network must be connected to every junction between diodes, not just at the ends.

Further good practice is to place resistors and capacitors in parallel with the diodes. The resistors act as a divider to equalize voltage stress along the string for dc and low-frequency ac voltages. The capacitors do the job for the high-frequency transients. This string is now quite dependable.

Full wave CT choke input .....No derating necessary
Full wave CT capacitor input .....Use only 70% of the current rating
Full wave bridge capacitor input ...Use only 50% of the current rating
Full wave bridge choke input .....Use only 70% of the current rating
Full wave doubler circuit .....Use only 20% of the current rating
Simple half wave circuit .....Use only 40% of the current rating

Fig. 6. List giving the approximate current deratings for various types of power supplies.

Other Suggestions for Supply Design

Manufacturers' transformer current ratings are sometimes rather optimistic, or rely upon test conditions not known to you. For a specific application, good practice is to make up a breadboard circuit that will load the transformer in the same way as normal operation in the proposed circuit. That is, if 100 ma load is expected, and a 1000 uf filter capacitor, this is quite different from a resistive load. Making up a complete rectifier circuit, you can check out the resulting system and see how hot the transformer actually becomes. See Fig.6 for suggested derating of transformers in various power supply applications.

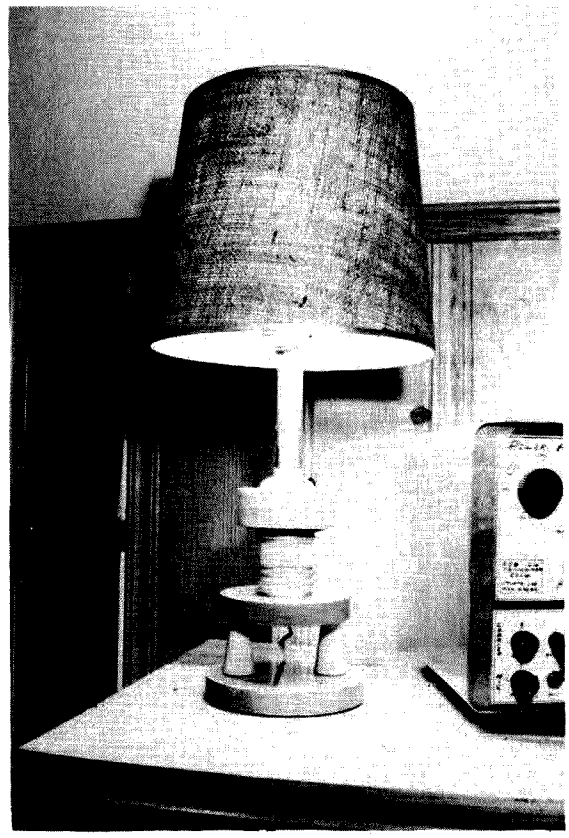
First Class Keyer Key

Having built several of the push-em and squeeze-em gadgets used to key todays automatic keyers, I was in doubt as to whether keys made with magnets, polar relays, brass stock and hinges were really worth all the effort. After all of my experimenting I came back to where I probably should have started in the first place. I modified my original bug.

My bug happened to be a Lafayette 99-2552, which sells for $10.95, but it is no different from any other bug. I like it because it has plenty of lead in its belly and rubber suction cups to grab the table.

Here is what I did. First I cut off the vibrating spring and weight end piece with electricians shears. This definitely commits you to the change. Tin snips won't fit down into the space to get at the spring. The two wire original cord was replaced by a three wire lead. The back original terminal is connected to the key lever arm underneath and this connects to the keyer ground. The dash terminal is the forward terminal. Run the third lead over to the left side of the key and fasten under the knurled nut used to adjust the stop. This is now the dot contact and the old dot contact is not used. Check out the key leads with an ohmmeter if there is any question.



This key has the advantage of feeling like the old bug, but after a few weeks practice with the automatic key you'll never go back to the old bug again. It does take a while to break the old sending habits, but after you hear the dots coming out so much cleaner than those scratchy old bug dots you will never regret the effort spent in learning the new technique.

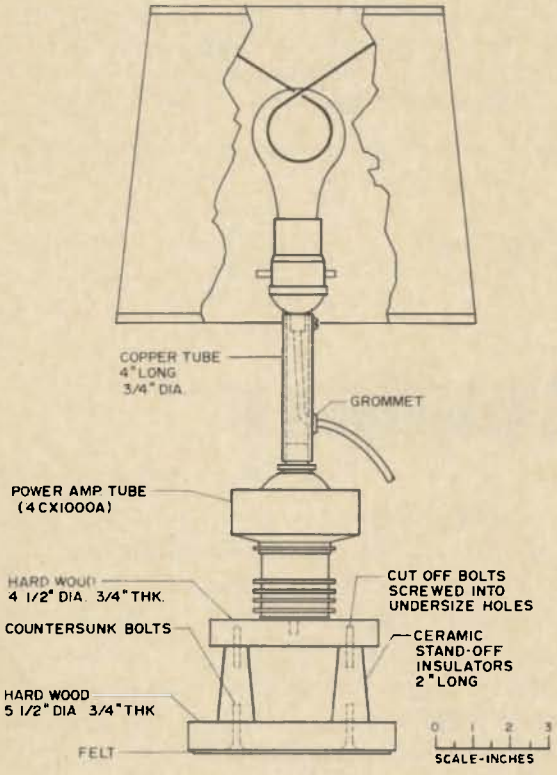
Converting the 4CX1000A into Lamp



The finished lamp is a real conversation piece.

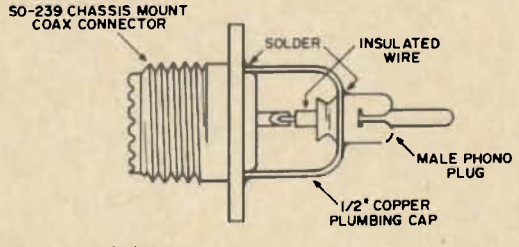
The average well-read ham knows exactly how to put to effective use his old TV set, burned out transistors, and half shot surplus diodes, but what to do with that $20 to $150 gassy final power amplifier tube presents a problem that almost defies even the most clever homebrewer. You can not just toss such an old friend into the trash can. Besides, who knows, wishful thinkers might expect it to start working again, after a well-deserved rest. Well, instead of storing it in some out of the way place until it's forgotten, here is a way to keep it intact and useful at the same time. Make a lamp out of it. Don't let out with the, "Oh boy, that caps everything" until you read a little farther. This project is very easy and I cannot think of another one more likely to go on without trouble. It will transform the XYL back into the loving wife when she finds that you must depend upon her shopping skill to select a lamp shade that matches the decor of the ham shack.

Construction

Glancing at the drawing (**Fig. 1**) you can see how a 4CX1000A was transformed into a really unusual conversation piece. This method can be used for any tube with a plate cap. The only changes that will have to be made are in the diameter of the copper tube post and the mounting holes in the base. All the connections to the power tube are press fit so as not to damage it. I could not get up courage enough to drill into such a magnificent dud; besides, the appearance of the lamp is enhanced with the tube showing signs of being in mint condition. The wood discs in this case were made of maple but only because there were two small pieces available. Any hard wood will do but it must be finished to as neat a polish as possible in order to provide the proper setting for the tube. After shaping and drilling, the bases should be sanded to remove all scratches with 200 grit garnet paper. Staining them to the color indicated by the wife is accomplished with ease using a Kleenex to wipe it on. The final finish is a coat of clear plastic spray that can be picked up at the variety store when you buy your socket and wire. The copper tube post likely will not fit the plate cap. In the case of the 4CX1000A the tube had to be expanded a little by driving a greased socket from a wrench set into it and then doing a bit of

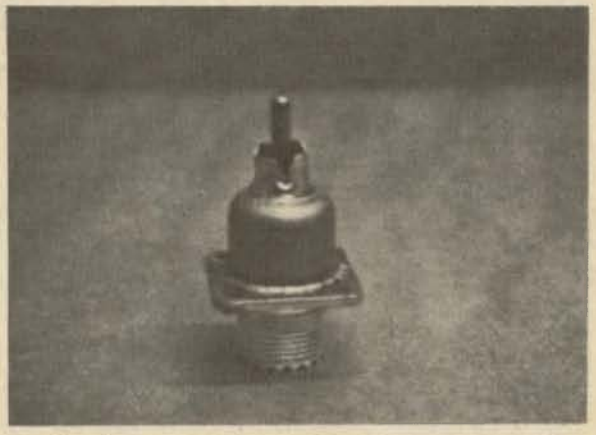
Fig. 1. Diagram of lamp construction.

scraping with a penknife. In other cases it might require some type of filler, but select a tube of a diameter where the least amount of modification is required. A great deal of strength of connection will not be necessary. The socket can be mounted as shown in Fig. 1 or a complete lamp socket kit can be obtained from the variety store that contains many cork bushings that can be used to adjust the diameter of the socket mount so it will fit almost any size tube. After completion, the copper post is polished with steel wool and along with the other metal parts is sprayed with clear plastic to prevent tarnish.



The effort of converting your defective power amplifier tube cannot in any way be in vain. If your wife returns to the XYL role and orders the thing out of the house because there is no place to plant Philodendron in it, pen your call in some prominent place and give it to a deserving chap to take to college with him. There certainly will not be a more "Now" lamp at the school and you will enjoy the bravos of the artistic world with Michaelangelo and Salvador Dali.

. . . K3QKO



Coax to Phono Plug Adapter

Several pieces of ham gear, notably Heathkits, use a phono connector for the antenna terminal. While these work well, most ham stations are set up to use coaxial terminations, and adaptors for this type of plug are not readily available.

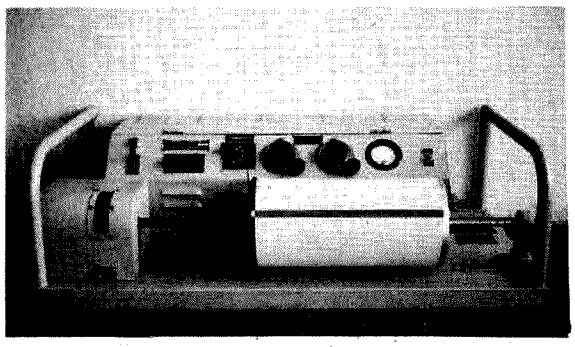
An inexpensive adapter can be made using an SO-239 coax fitting, a phono plug and a ½" diameter copper plumbing cap. The results are a structurally rugged adapter with electrical properties considerably superior to the usual "plug dangling at the end of the connector" type that are so common!

Drill a 3/8" hole in the copper end cap and solder the phono plug in place. Snip off about 1/8" of the coax terminal, to prevent it from shorting to the phono plug when the unit is assembled. Solder a 3" length of insulated wire to the terminal, and pass it through the phono plug. Solder the copper cap to the coax fitting, then solder the wire to the phono plug. Check with an ohmmeter to make sure there are no shorts between the center conductor and the outside of either fitting.

Originally, I intended to file away the flange around the coax fitting, but later found it to be an advantage as it provides a firm finger gripping surface when attaching and detaching the adapter.

The total cost of the adapter, using all new components, came to sixty cents.

Bud Michaels, WB2WYO



The death of Ralph L. Steinberg in September was a loss to 73 and its readers. His articles have always been of unusual interest, and all of us extend our sympathy to his wife, Lillian.

Facsimile and the Radio Amateur

Ralph Steinberg K6GKX

In the December 1968 issue of *73*, this author made mention of several pieces of facsimile equipment which were used in the summer of 1968 to transmit pictures to the Antarctic. Since then many requests have been received to give more details about the equipment and operations.

To get better acquainted with facsimile, this review will cover some of the mechanical and electronic operations of the TXC-1B facsimile transceiver, MD-168/UX modulator, RD-92/UX recorder and the CV-1066A (CV-172A/U) receiving converter. These are necessary for receiving and transmitting at any facsimile station.

TXC-1B Facsimile Transceiver

This transceiver is quite versatile and can receive photos, sketches, maps or any printed matter either by electro-mechanical optical or stylus needle operation and also record photographs in either negative or positive form. For transmitting, it will handle four 5 x 7 or two 8 x 10 inch photographs in one operation. Color pictures may be transmitted but all reproduction is in black, white or shades of gray.

Three operations are required in transmitting and recording. These are scanning, transmitting,and recording. (See **Fig. 1**) The scanning operation is that of dividing the picture into a large number of elemental segments and this process is accomplished in the facsimile transmitter by a scanning drum and photocell arrangement.

The picture to be transmitted is mounted on a cylindrical drum, which revolves at a revolution speed of once per second and travels along a lead screw (96 threads per inch) at the rate of 12.5 inches in 20 minutes. Light from the exciter lamp illuminates a small segment of the moving picture and is reflected by the picture through an aperture to a photocell. The amount of light reflected back to the photocell is a measure of the light and dark segments of the picture being scanned. During the transmission of a

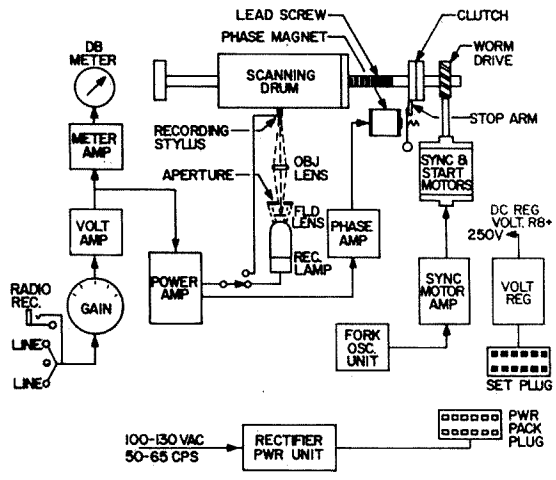


Fig. 1. Receiving block diagram, facsimile transceiver TT-1/TXC-1.

complete picture, this light traverses every portion of the picture as the drum slowly winds around past the fixed lighted area. The reflected beam of light into the photocell, creates voltage variations into the output circuit and establishes the picture signal.

Signals being received by the facsimile transceiver are amplified and serve to activate a recording mechanism that makes a permanent record on the sensitive recording paper and at the same time synchronizes the transceiver drum until the complete picture is reproduced. Synchronization is obtained by driving both the receiving and the transmitting drums with synchronous motors operating at exactly the same speed. The drums can be operated at 30,60,or 120 rpm. The older type models are usually operated at 60 rpm but the newer models operate mostly at 120 rpm.

Framing (positioning) the receiving drum with respect to the transmitter drum, at a distant station, is done by transmitting a series of phasing pulses just before a picture transmission is to begin. The pulses operate a clutch mechanism that starts the scanning drum in the transceiver so that it is properly phased with respect to the starting position of the scanning drum in the transmitter.

A start motor mechanically coupled to the synchronous motor serves to increase the synchronous motor speed above synchronism during the starting period after which it coasts down to synchronous speed when operating on 1800 hz power.

The facsimile signal from the radio receiver is attenuated at the gain control of the facsimile transceiver and then amplified in the voltage and power amplifiers. The power amplifier output drives either the photographic recording or the recording stylus for direct recording. Another circuit from the power amplifier transmits phasing pulses to the phase amplifier, which operates the phase magnet and clutch during the phasing process just before each picture transmission.

The fork oscillator unit develops an output voltage that is applied across the bridge modulator. The frequency of this voltage is 1800 hz. When the bridge is balanced (photocell dark), the output voltage is zero. When the amount of light falling on the photocell varies, the resistance of the cell varies. This action unbalances the bridge and produces an output voltage that varies in amplitude with the variations in light. Thus, the 1800 hz voltage is amplitude modulated in the bridge modulator.

MD-168/UX Modulator

This modulator is designed to convert amplitude modulated facsimile signals from the TXC-1B transceiver to frequency modulated signals.

The input signal to the modulator has a frequency of 1800 hz and an amplitude that varies with the light and dark segments being scanned at the facsimile transmitter. The output signal from the modulator is an audio signal in which 1500 hz represents the maximum signal (in amplitude) and 2300 hz represents the minimum signal input to the modulator from the facsimile transmitter. Amplitudes between maximum and minimum signals are changed to corresponding frequencies between 1500 and 2300 hz. Since the audio frequency shift signal from the modulator is of constant amplitude, the emitted radio frequency carrier is modulated at a constant percentage of modulation.

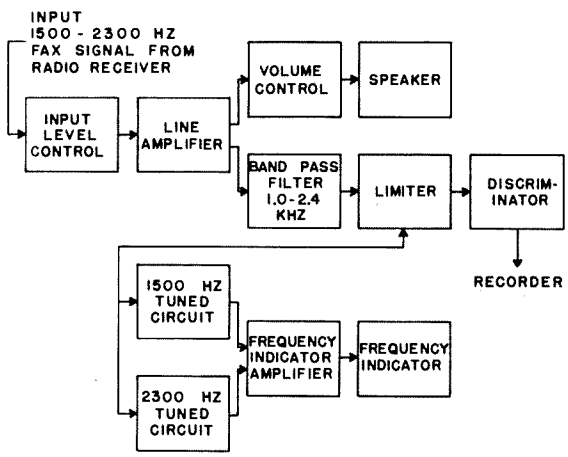

Fig. 2. Block diagram of CU-172A Converter.

CV-1066A (CV-172A/U Converter)

This converter is used to convert the 1500 to 2300 hz facsimile signals received from a radio receiver to AM signals suitable for operating the facsimile recorders like the RD-92A/UX or the TXC-1B facsimile transceiver.

The facsimile signal from the radio receiver is fed through an amplifier and filter

to a limiter and then through a frequency discriminator. The discriminator is a low-pass filter having a cutoff frequency of 1500 hz. The output of the filter at 2300 hz can be adjusted to be from 10 to 20 db lower than the output at 1500 hz. The input signal is then changed from audio frequency shift signal of substantially constant amplitude to an output signal of varing amplitude in which the maximum amplitude is 10 to 100 times the minimum amplitude. See **Fig. 2.**

RD-92A/UX Facsimile Recorder

The RD-92A/UX recorder will make copies of recordings transmitted by the TXC-1B facsimile transceiver or equipment having the same transmission facilities. See photo. It has some similarity to the TXC-1B transceiver in that both are able to use the stylus needle for recording. Recording by the RD-92A/UX is done by rotating a drum at constant speed, while feeding a stylus needle along the drum, one scanning line for each revolution until the complete drum has been covered.

An amplifier-detector unit receives the input facsimile signal. This signal, consisting of phasing pulses and facsimile information (messages, drawings, maps, etc.) between the frequency limits of 900 and 2700 hz, is amplified by a class A amplifier and demodulated through the action of a full wave rectifier and low-pass filter to form a varying dc facsimile signal. The varying dc facsimile signal output of the amplifier-detector is coupled to the amplifier modulator where it combines with a 15 hz oscillator in the modulator stage.

The signal from the amplifier modulator is amplified by the print driver and amplifier to sufficient intensity, so that, when connected to the stylus needle in the recording mechanism assembly, it will record on the

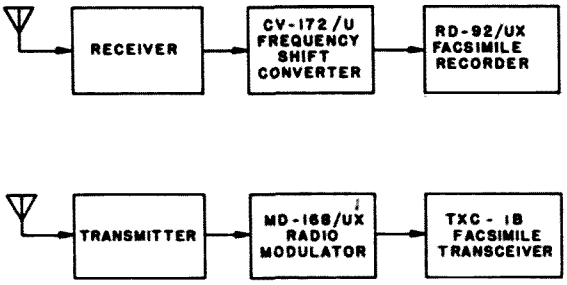

Fig. 3. Block diagram of the transmitting and receiving facsimile equipment.

recording paper points representing varying shades of dark elements of the transmitted copy.

The RD-92A/UX recorder is used aboard ships to receive weather maps and information. It can copy recordings 12 x 18 x 3/4 inches. The input impedance is 1600 ohms and the drum speed is at 60 rpm.

Applications

For amateur radio facsimile operations, the TXC-1B facsimile transceiver can be used on any of the vhf, uhf or microwave bands using either AM or FM modulation. If AM modulation is used, all that is necessary is to plug the facsimile transceiver into the input of the modulator of your transmitter. If FM is to be used, it will be necessary to have the MD-168/UX modulator in the place of your present modulator.

To receive facsimile, either the TXC-1B facsimile transceiver or the RD-92A/UX recorder can be used but it is necessary to use the CV-1066A (CV-172A) receiving converter. See Fig. 3 if you wish to copy the weather stations in all parts of the world. All of them use frequency modulation. Copying weather maps (see Fig. 4) is good experience to become proficient in facsimile operations. Once you get the knack of it, you can be your own weather man.

Weather stations are located in San Francisco, Washington, D.C., Pearl Harbor, Guam, Tokyo, Kodiak, Alaska, Edmonton, Canada, New Delhi, India, Canberra, Australia, Khabarovsk (USSR), and Cambridge Bay, N.W.T. For time of transmission and frequencies of these weather stations (Fig.5). There are others in England, Germany, Turkey, Sweden, Spain, Norway, Morocco,

Facsimile is growing more popular each day. Here in the Southern California area there are twelve stations operating and several more have equipment and will be operating soon.

. . . K6GKX■

Mr. Steinberg's articles have been popular with 73 readers—so much so, in fact, that the author frequently found himself engaged in correspondence with his fans long AFTER publication. His untimely death, of course, cut off this correspondence flow. Mrs. Steinberg has, therefore, submitted a few of Ralph's recently received letters to 73, with the thought that perhaps they might be answered by another amateur knowledgeable in the field:

Dear Ralph,

Recently read your article in June issue of 73. I agree with you on FAX. It was a short article and very practical. I enjoyed it and must compliment you on it. I'm with the SSTV gang that meets on Saturdays at 2 p.m. (New York time) at 14.230 MHz. Please send me as much information as you can on FAX (self-addressed stamped envelope enclosed).

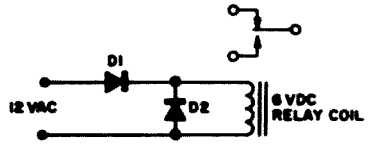
Philip J. Lupi WA2NHH
1225 Hillside Place
North Bergen, J. J.

Dear Mr. Steinberg:

I just found your article in the June '67 issue of 73 Magazine about the TS34AP. I have just acquired a good TS34 without the lens or hood (not modified as in your article). Do you know anyone who has made the conversion recommended by you—who still has the lens and hood and would sell them? I used one of these scopes once and would rather have the original configuration.

David Potter
2844 San Gabriel
Austin, Texas 78705

Dear OM:



My friend Ted Cohen, W4UMF, told me about your activities in FAX. Because I am working FAX some years now and have been unable to contact some boy in the States, I ask for your help.

In past time, I contacted W2BK (Ray P. Clurmann), but recently I have been unable to establish contact with Stateside amateurs. I would like to know the systems and schedules of operation so that I may attempt a FAX QSO with you. I particularly need to know if you Americans can use the HF bands to work FAX. I regularly work 14087 kHz in FM mode (FSK), with Cooperation Index 576 or 288, positive or negative transmission, 30, 60, or 120 rpm. Some time back, I copied transmissions from States to Antartica with medium success. Is there a possibility that I might join you in FAX activity?

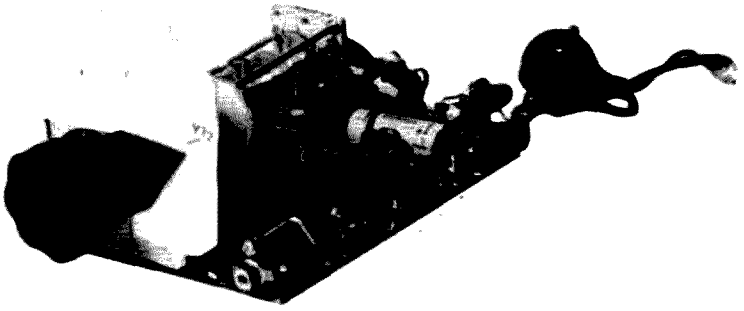
USE DC RELAY ON AC WITH DIODES



Another good way to use diodes is shown below. I needed to run a 6 vdc antenna changeover relay on ac. This is how I did it.

On the positive half cycle, diode D1 conducts, passing current through the relay coil, which builds a magnetic field. On the negative half cycle, this field collapses, and the resulting current is passed through D2, which shorts the ends of the coil together for the negative half cycle. You will note the current always flows through the coil in the same direction. Thus the relay operates as if it were on pulsating dc. In operation, there is almost no audible noise from the relay coil.

Solid State Double Bandwidth Tunable IF Solid State Converters

This may sound like a lot of "solid state" but it does help get the idea over that there are plenty of battery-operated vhf and uhf converters on the market, but what are you going to hand-carry for a tunable i-f on that mountaintop or while camping?

Of course you can put your communication set in your car, haul an ac putt-putt along, drag it 100 feet away from the car, and *go*. It is peculiar though, the dim view Forest Wardens take of this racket going on all day Sunday with all those visitors around each paying 25¢. I did this for years and often had to lug the generator 100 feet *down* the mountain top on the side to keep it quiet.

So, our tunable i-f will help this situation, working on your favorite band, six, two, 432, or 1296 mhz, and even 2400 a little later.

Ten meters is used because that gives you a nice ten meter receiver for portable use, and when you're on 432, or 1296 you need at least 30 mhz to keep the image down.

Design Philosophy

This is a straightforward job with one rf stage, a mixer, and an oscillator, all tracking on a three gang capacitor from 28 to 30 mhz. See **Fig. 1**.

"Bipolar" (which means just the old-fashioned, regular triode type with three leads) transistors are used to keep down the cost and time of construction.

An S meter connection is shown because when you're using that high gain sharp beam up there, it's nice to know just where it does peak! And by how much, even if it's only relative.

General Notes

At this frequency, 28 to 30 mhz, almost any good vhf transistor does a good job. There is gain in the converter ahead, and gain in the i-f following, so you don't need much here. Once again, though, you do need tracking. There is a whole section on a painless method for doing this in this article.

The main tuning (or ganged) coils are all wound identically, to help in tracking, and with the exception of the oscillator collector, all other circuits are lightly coupled to them.

L1 brings in the first i-f from the 6, 2, 432, or 1296 converter, at 28 to 30 mhz on J1. If you just happen to put almost any kind of antenna into J1 you may be surprised at the ten meter signals you hear. Just incidental.

Note that for the sake of uniformity and ease of wiring all eleven coils are returned to ground on one side. This accomplished by dc blocking capacitors from the bases, which are dc fed by resistors, and by the use of the

L1	3 turns, no. 28 DCC, close wound on ground end of L2.
L2	17 turns, no. 26 DSC, on 6/32 tapped form, 5/32 O.D., with 6/32 threaded, powdered iron core.
L3	2 turns, no. 28 DCC, as L1.
L4	2 turns, wound close on L5.
L5	As L2.
L6	3 turns close wound on L5.
L7	4 turns on L8.
L8	As L2.
L9	2 turns on L8.
L10	1 inch long iron core, 5/32 OD wound for 2 mhz, two pi.
L11	4 turns on middle of L10.

Table 1. Coil turns.

collector dc voltage being at the baseboard level. Note that by this method most bypass capacitors are eliminated.

The copper-clad baseboard also makes it easy to ground all coils on one end. The capacitors are all the 1000 pf little ceramic jobs from Lafayette, 3/16ths of an inch square. C1-A, B, and C was a Bud three gang with 11 pf per section. For this unit, I removed one rotor plate from each of the three sections, and also spread the 28 to 30 mhz tuning range over 80 percent of the dial.

If you have a converter or converters having other than 10 meter outputs, you can change the coils to suit. The main reason here for choice of 10 meters was the large number of "amateur band receivers" with 10 being the only band with nearly 2 mhz tuning range. This should cause converters with 10 meter outputs to be in the majority, although I have not checked with converter manufacturers on this.

All transistors just happen to be Sprague 2N1726 (four years old right now) but you can use almost any good vhf ones, as the noise figure and gain are set elsewhere. The main deal here is to *tune* something so you can use crystal control for the uhf local oscillator where it is needed.

No critical points were found in the tune-up of this unit. For permanent use, installation in a Minibox should be used, matched to your favorite dial.

Summing up, this article is to show you how easy it is to make a good, low cost solid state, tunable i-f section as a necessary part of battery operated rigs for 6, 2, 432, and 1296 mhz. After all, isn't it better to be up on a mountain in the summer, and on the air, than to sit in the shack all the year round?

Details—RF Stage

The rf stage (refer to Fig. 1) has a tuned circuit in the base, with an untuned collector brought over to the mixer on L7. As detailed in the tracking section, the iron core is used to set the low frequency end of the tuning and the trimmer C2 sets the high frequency end. Trimmers C2, C6, and C11 also serve to spread the 2 mhz range over the dial. Battery voltage is high on the collector end of these stages which makes things a lot easier, especially for bypassing, as you will see.

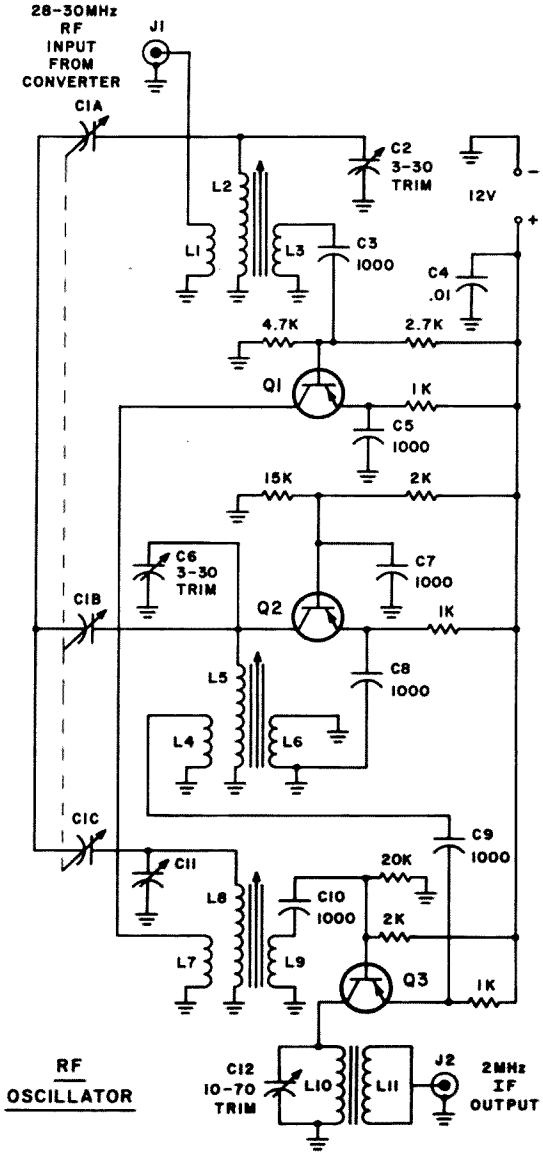

Fig. 1. 28 to 30 mhz tuneable i-f.

Oscillator

The oscillator is a sure-fire emitter coupled job, with the collector on the high end of L5. This is done to "set" L5 as the "slowest" tuning coil of the three. The other tuning coils, L2 and L8, are then made to track with a little more trimmer capacity, matching the collector capacity of the oscillator on L5.

Oscillator output is obtained from L4 and capacity coupled to the mixer emitter. Starting from ground, wind L4 on L5 in the same direction as L5's winding, and put the emitter of Q2 on the other end. It *has* to oscillate! There is a simple law of nature that says; "If a good transistor has good coupling back from a *good* collector coil so that the base goes negative when the collector goes positive, it will generate the signals you want, upon application of good voltage."

Mixer

Note first that the mixer uses the gang capacitor section furthest away from the rf section. The rf stage has never shown any sign of nuisance feedback in this tuner so far, but it's a good precaution anyway, to keep those sections apart. No shielding was needed either, but you might just need some if you try to make the unit smaller. It's six inches deep, by five inches wide by one and three quarters high now, not including the dial.

Tuned energy from the rf collector is brought to the mixer on 4 turn coil L7, and local oscillator input is capacity fed to the mixer emitter. The output coil L10 was tuned to 2.5 mhz in this unit, although you can use a little higher or lower if you want.

As a general rule a ten to one conversion frequency is good, but you are on a trade-off here: a high ratio will make your next i-f more selective but your image possibility will increase. A low ratio will make the image disappear but then you haven't done much conversion and you may need *more* converters to get you down to the final i-f you're counting on. More on this in Part Two where the "double-bandwidth i-f" is detailed. This is where you build a diode into each i-f section with separate volume controls for instant mixing into one af amplifier. This will give you broadband for quick and easy search, and narrowband for demodulating that weak signal from two states over!

Special Separate Section on Tracking

There is a very straightforward positive method for lining up coils for ganged capacitors, which will be detailed here, using the 28 to 30 mhz tunable i-f of this article as an example.

We start here with the circuit already designed and working correctly with three separate capacitors, one of which may be the oscillator section of the gang used.

The ganging together of the frequency versus rotation of the three section variable capacitor is not a matter to be taken lightly, however. Due to slight differences in the circuitry of the rf, mixer, and oscillator stages and their coupling, it is not enough to buy three movable iron core coil forms, wind six (example) turns on each coil, and expect them to track. The grid-dipper will not do the whole job either, although it may help some to get you started.

The first thing is to cover the range needed with the variable capacity of one of the sections of the gang, and still leave some capacity at the high end for the best Q. This residual capacity is furnished here by the parallel trimmers, which are of considerably greater capacity than the ganged sections, so that the L/C ratio actually changes very little over the range tuned.

Assuming you already have chosen the ganged capacitor suitable for the frequencies involved, which appears to be less than 10 pf per section (as I had to remove one rotor plate out of three from an 11 pf unit), check out which of the three stages takes the most variable capacity to tune the range. This will generally be the oscillator stage in this circuit. This is the one you will line up first because it is easier to stretch the frequency over the dial than it is to compress it.

Referring to Fig. 2, we will be concerned with connecting and disconnecting the three points shown, which will be designated hereafter by rf, mixer, and oscillator.

Now, using the completed unit, with two external capacitors temporarily tuning the rf and mixer stages, and operating into the i-f

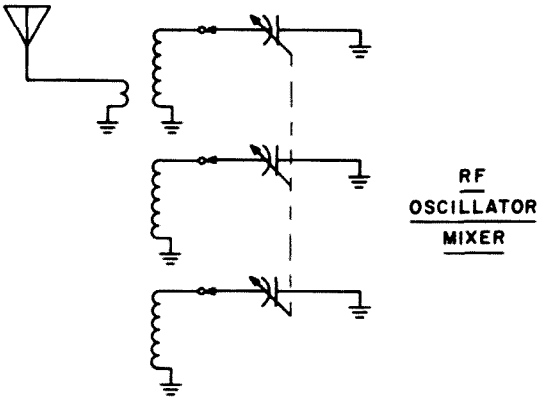

Fig. 2. Major connections for tracking.

you are going to use, such as 2 mhz, be sure everything works correctly, such as sensitivity, tuning range, absence of feedback in the rf stage, etc. Use an "S" meter or avc meter for this work. Tune the oscillator with one of the three ganged sections, and log three or five frequencies on Table 2. The dial must be in its permanent form. I used 28, 28.5, 29, 29.5, and 30 mhz for this purpose. The dial may also have any other scale as well on it that you may wish to set up, such as 431.9 to 434.1 for example. To make this unit you do need a signal generator, at least one of the $30 to $40 kind.

Some "quickie" manufacturers use only three points on the dial such as max., middle, and min., but that results in a $9.95 "radio." If you want to do a real job use five spot frequencies (as suggested above) for the 10 meter band as i-f for this tuner.

You can use 30 to 32 if you are afraid of rf leakage input from the 10 meter band. This whole unit should be ready to install in a Minibox with a good cover, so you should not have any trouble with i-f leakage on any frequency.

MHZ	RF	MIX	OSC
28			95
28.5			74
29			53
29.5			28
30			10

Table 2. Dial logging scales.

Now log on paper, the five frequencies chosen on a simple chart as in Table 2. You can see now the basic idea of this system. You have a positive, visible, and exact recording of the tracking of one of the gang

sections set up. Leave the oscillator core and trimmer set from now on so that these settings do not change unless a new start is to be made. This sometimes happens!

Now take the oscillator off the gang and solder the rf on. All you should have to do now for the rf is to set the iron core to trim the low end of the range, and the parallel pad trimmer to set the high frequency end. It's not always that easy though.

Right here you may have to do some readjustment of circuit values, and possibly some hard work! The rf may not track in the middle after lining up both ends! Or vice versa.

This is the reason for those funny-looking saw cuts you may have seen in the two outside plates of millions of ganged capacitors for over forty years! However, with the components and circuit shown in the overall schematic you will probably make out all right, although this section is intended to help you use other components, as well as helping on other frequencies.

The procedure is fairly straightforward now. Just make the rf readings coincide with those of the oscillator previously recorded by adjusting the core and the parallel trimmer. Using less core (that is, the core further out of the winding) and more trimmer you will of course "stretch" the readings on the dial. Make several runs this way and you will soon get the hang of it. And, you don't have to guess, it is logged down on paper for you.

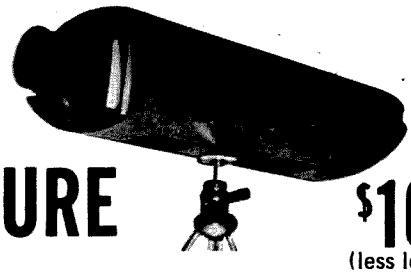
Mixer

Now disconnect the rf, connect the mixer, and proceed as above. You should now be able to fill in the third column and be ready for the big deal.

Oscillator and Three-Gang Tracking

If the oscillator has been previously logged correctly, and the other sections fitted to those readings, on soldering all three together you should have no trouble. Don't fiddle too much with the adjustments after soldering all three connections back onto the gang, because you have no means of knowing what the curve of any one section, except the oscillator, will be.

The reason for some gang capacitors having different oscillator and rf sections, is mainly because the broadcast band has a three-to-one tuning range in frequency, whereas the oscillator for a BC band radio needs about a two-to-one tuning range.



When you are running at 28 mhz however, and the mixer is at 28 to 30 mhz, the oscillator is only some two mhz away. The tracking ranges are so close to being identical that no effect can be noticed. So in this case use a ganged capacitor in which all the sections are alike.

That's about it for this positive method of tracking procedure. It has always worked for me since 1928!

Conclusion

All you need now is your favorite band converter in front, one or two fixed tuned i-f strips following, two lantern batteries for a 12 volt supply, an af amplifier, a crystal controlled transmitter, another af for modulator, a good portable beam, a carrying rack of plywood with shelves, a walk-up mountain, and the right companion!

to find more bores per square inch than at any other time in our cycle. We are fed a diet of indigestible pap, the asininity of which is so transparently designed - solely to get our votes - as to be intolerable!

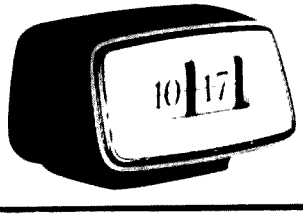
But don't imagine for a single moment that only American politicians conform to this sorry pattern. Other lands, far-flung and remote, suffer greatly from this same lamentable pathological disorder. They too are faced with the same loudmouthed, self-proclaimed geniuses, spouting the same claims of omniscience, with the same panaceas and nostrums for curing all the world's ills. (I do believe that when certain foreign politicians threatened that they would one day bury us, they really meant that they would bore us to death!)

The main trouble with politicians in general is that they have absolutely no sense of humor. They refuse to regard themselves with anything less than utmost seriousness. They are sublimely pompous because they claim to have absolute solutions for evils which have existed without any solution since the earliest beginnings of mankind. I sometimes think that they create some of these problems deliberately, so as to use them as fulcrums upon which to poise their perpetual quest for public office.

Years ago, and for what seemed an interminable period, a pig farmer in Secaucus, New Jersey, persisted vainly in running for the Presidency. Now, in retrospect, and speaking with serious objectivity, do you suppose, really, that he would have done terribly worse than some of our recent Presidents, governors, or mayors? Truly, I am inclined to doubt it.

* * * *

I've always found it fascinating to speculate upon the odd and wholly illogically logical sight of a clergyman blessing an artillery piece, a torpedo, or a rocket launcher on the eve of battle. Undoubtedly this monstrous distortion takes place on both sides, so that Providence must eventually either choose a preference through favoritism, or throw up the hands and ordain a pox on both houses.



Enlightened societies long ago dispensed with that old anachronism, the divine right of kings. But they have never quite overcome the perverted morality of religious righteousness of military adventure. Somehow there has developed a duality between armed conflict and religion. Saint Joan was above all a soldier. The Crusades were holy wars. Kings were called "Defenders of the Faith." And the most heinous cruelties ever known were committed in the fifteenth century by the Inquisition, a quasi-military arm of the church, whose entire thrust was based upon punishment for the crime of heresy.

I do not know, nor can anyone calculate the numberless masses slain in holocausts which were countenanced and blessed by religious authorities. From the time of the Israelites and Phillistines upon the plain before Shochoh and Azekah, and even before that, when Joshua chose out men in Rephidim and fought Amalek, people have perished in agony, fighting i n wars sanctioned by Divine Authority. The entire lexicon of mankind is filled with examples of this carnage, running through the tapestry of our history like a scarlet thread.

Is it not a strange and inexplicable wonder, that all the combined prayers of wives, sisters, fathers, mothers, and brothers have not had the potency of a single incantation, mumbled over an artillery shell or a fragmentation bomb by a military chaplain?

It is possible, of course, that our world has periodically been weighed in the balance, as in ancient times, and has been found wanting. It is likely that Armageddon will continue to recur over and over again, until we humans finally decide to beat our swords into ploughshares.

VHF-FM: A New Involvement

The call "K6MVH" on the masthead of 73 will doubtless cause the eyebrows of about 4,000 subscribers to raise an inch or so. That's how many 73 readers there are who also receive monthly FM Magazine, a "splinter-group" publication that I have co-owned and edited for the past several years.

What Ever Happened to FM?

FM Magazine almost went the way of all prior splinter mags. Like VHF Horizons and the VHF'er, FM Magazine was well received by the amateur radio operators but virtually ignored by the advertisers. The journal was costing more than it was making. Mike Van Den Branden, its originator, paid for the enormously expensive printing, binding, and distribution costs; I paid for the typesetting cost and author remunerations. But there came a time when the costs were simply too much for me to bear. I accepted employment with an out-of-state firm, and was forced to abandon my expensive but pleasurable hobby of supporting the financially ailing FM journal. My partner elected to stay with it. He cut costs by thinning down the magazine and changing the page size, and is determined to make it go. He deserves success.

The fact that so many amateurs were active in FM (with repeaters, mobile telephones, and remote base stations) was sufficient justification for me to want to stay in the field. So, after turning over my share of FM Magazine to Mike Van Den Branden, I got in touch with Wayne Green.

To my mind, Wayne is a smart cookie; he is ever watchful for trends and new things. He was publishing articles about the real FM while the other journals were ignoring the fact that FM existed except as a switch position on a piece of AM gear. And lately, he has been emphasizing the repeater element even to the extent of personally communicating with as many repeater owners as he could to get information about frequencies, operating practices, ideas, and such.

73's Role

So it was that I proposed to Wayne the initiation of an FM/repeater segment of 73 Magazine. Categorically, 73 is opposed to departmentalized publications. Wayne's experience began in an amateur publication that was so departmented structurally that little room remained for general technical articles. His feelings along the lines of columns, multipart articles, and departments have not changed to this day. But Wayne shares with me the thought that FM operation is a cow in another stable. What was once a splinter group has become a chunk group. And it promises to engulf an even larger share of VHF operation in the immediate future.

Thus Wayne was not particularly keen on the idea of a column, but he could see the need for intensified coverage of the fast-moving field of repeaters, remote operation, and amateur FM. As a counterproposal, he suggested that I move to New Hampshire and serve as editor of 73, where I could work in FM articles regularly as a balance to the already abundant fare being served up monthly for all phases of amateur radio. It meant broadening my interests, of course, but a quick self-appraisal revealed the desirability of this—so, I packed my bags.

Now that I've been sold on the other interests amateur radio has to offer, I feel obligated to tell others about the advantages of FM. (Let's ALL be well balanced.)

The reasons for the popularity of FM are as varied as the interests of the operators, as any seasoned FM'er will attest. But FM's strongest points are these: Getting started is easy, and the results are more than proportionate to expenditures—particularly where repeaters are involved; there is an acknowledged superiority of equipment performance and operation over AM equivalents; and finally, FM is still an area where innovative thinking, pioneering, and experimentation are possible, in such branches as control design, link interconnection and deployment, telemetry, and even public relations.

That's the background. Now, 73 Magazine will carry FM articles with regularity. They may be technical, construction, instructive, generally informative, or conversion types, and they will be geared to the needs of the new discoverer of FM as well as the long-time operator. 73 will attempt to carry the same overall philosophy as it has carried with the entire magazine in the past: plenty of meat for every reader of every level, every month.

Spread the Word

There is lots of room in 73 pages for articles, and the pay has never been better. So those of you who have come up with a better carrier-operated relay for a repeater, or who have developed an antenna that gives better vertical separation, or who have found new ways to get higher repeater sites, start writing. Show the rest of the world

photos of what you have done, schematics of what you built, or system diagrams of what you have designed. And watch these pages to see what the others are doing.

... Ken Sessions ■

Ed. Note.
For those new to FM, Ken Sessions' recently published, hardbound "Radio Amateur's FM Repeater Handbook" starts at the technological rockbottom and goes right through all the simplified details of building a repeater and keeping it on the air. His book is currently available at all major electronic distributors or from the publisher, Editors & Engineers, Ltd., New Augusta, Indiana.

BCI in Stereo

Some transistorized stereo systems are susceptible to BCI from *rf* energy in the 3.5 to 30 mhz range. What happens is that the long lengths of the speaker leads and power cord act as antennas, feeding *rf* energy to the first audio stage where it is rectified and amplified in succeeding stages. The solution is to add ferrite chokes in each lead.

The ferrite chokes consist of a 3" piece of ferrite rod about ¼" in diameter or larger, wound with at least 25 turns of each speaker lead and power lead. Begin winding as close to the chassis as possible. Some units are equipped with plugs for each speaker lead, which is a good place to begin. The speaker leads are usually zip cord as is the power cord, so that when you have at least 25 turns of wire wound on each rod there will be about three layers of wire on each which can be held in place with any ordinary tape you have available.

The ferrite rods can be obtained at most radio supply houses as ferrite antenna coils or loop sticks. They come with a coil of wire on them which is removed and discarded. Some rods are 6" in length. To make two 3" pieces, score the rod with a file at the 3" length and tap it on a hard surface and the rod will break cleanly.

After installing the chokes in each speaker lead, try out the system, both radio and record player; you may be lucky and not have to choke the power cord. But if there is a trace of BCI in either the radio or the record player add the power line choke, again beginning the winding as close to the set as possible, although it will probably work if you begin winding at the plug end of the cord.

(continued from page 93)

There has to be an answer to all this somewhere. I find it hard to understand how anyone can place other considerations higher than this one on his list of priorities. Everyone in this world should be hoping, praying and working for peace. And, for a change, we ought to be blessing not cannons, but school books . . . not machine guns, but construction tools and agricultural implements.

If we do not accomplish this change now, we may not get another chance to do it. As the highway signs says . . . "Last stop before exit!!!"

* * * *

There has been a ridiculous emphasis on bust fetishism over the past twenty years or so, which has proliferated into gigantic proportions, no pun intended. We seem to have carried this mammary-mania so far that it appears unlikely for it to develop further (again no pun intended) short of making the topless fad universal.

Now, for myself, I object strenuously. When there is nothing for the imagination to conjure, what is left?

There were times in the past when the same shamelessness became an accepted way of life. The ancient Etruscan ladies adorned their bodies with jewels, metals, cosmetics and heavy drapery, but allowed their bosoms to remain bare, a display which was thought to be esthetically attractive. But it did not help the Etruscans to avoid falling into ruin. The Roman legions, unhampered by the distractions of abundant feminine pulchritude, were able to beat the Etruscans into submission, without any difficulty whatever. Thus perished one of the earlier powers of Europe, a victim of its own unhealthy preoccupation with prurience.

From what I have seen of the open display of the female thorax in the more primitive areas of the world, it seems clear that these manifestations occur in direct inverse proportion to the degree of civilization. Most of these savage societies are throwbacks to the prehistoric eras, with scant development of agriculture, communications, or transportation. They consist principally of tribal groups, limited in area, governed by taboo and ju-ju, unaware of the slightest advance in the human state of being.

It would probably be quite pleasant to spend lazy days and soft nights lolling on the tropical South Sea sands, or listening to the plashing of river wavelets lapping at the banks of an African savannah, while tall, statuesque, ebony- or cinnamon-hued Venuses slink seductively by. I can even dream of being handed a tall, icy drink of what-you-may-please by an amply endowed vixen with soft-as-velvet epidermis whose sole function in life is to make me realize my masculine irresistibility. But when I think of riding in the New York subway on a chilly February morning gazing at huge expanses of pale, flabby, goose-pimpled, naked flesh, somehow the picture of the tropical idyll fades into the background of forgetfulness.

A friend of mine, hungry as a ravenous bear, unsuspectingly stopped in at a place in Greenwood Lake, where they employ topless waitresses. He had in mind a juicy sirloin, french fries . . the whole bit. When the waitress came over to take his order, he arose, stumbled spastically to the bar, ordered a bourbon boilermaker, and went his way . . . a chastened and a shaken man, mumbling to himself.

So, if you don't mind, I take my stand against all this open display of superdeveloped thoracic anatomy. Down with the Playboy centerfold. Down with cleavages, uplifts, and bikinis. A fellow has to be able to reserve something for quiet contemplation and solitary appreciation. If all our secret little fetishes are permitted to flourish out in the open, we might start to cultivate vices that are truly harmful and destructive. Three cheers for purity, modesty, chastity.

* * * *

Well, there you are . . . and as the dentist said, "Now that wasn't so bad, was it?" We've covered the three taboos, and I doubt whether I've trod on anyone's toes, or hurt anyone, or violated many sensibilities.

It occurs to me, now that I think of it, that all the objections to having discussions about these allegedly sensitive areas has, for years, been based upon a false footing, a subterfuge. While it was always stated that these topics should be avoided so that no one's feelings might be hurt, the true reasons for the proscription was something altogether different. Such discussions tend to examine the underpinnings of society, the basic structure and nature of the entire human community. A too close scrutiny of these elemental foundations is very apt to disclose some dry rot. And it is to the advantage of certain groups and individuals within society to preserve the status quo and resist change. People have been conditioned to avoid such analysis.

I have a suspicion that the strongest and most vocal opponents of free discussion on these points are not at all concerned with the delicacy or indelicacy of such dialog at all. Political discussions are not viewed with favor by political scoundrels and grafters. Religious discussions are not popular with bigots, zealots, and fanatics. And sexual discussion is unpalatable to evil-minded puritanical, inhibited, perverted, or otherwise abnormal misfits. Everywhere they see revolution, blasphemy, and carnal sin.

There once was a well known sect called the Shakers, who believed that man's physical nature must be contrary to the Almighty's design - the work of the devil, therefore a sinful thing. They did not even countenance procreation among their own community, with the inevitable consequence . . . the Shakers disappeared from the scene. As did the dodo bird, the wooly mammoth, and the pterodactyl before them, they were unable or unwilling to adapt, so they became extinct. In the struggle to overcome a hostile, changing environment and survive, all species must evolve, adapt, accommodate. For the environment invariably prevails . . no matter how strongly the changes may be resisted.

Inexorably, our world will become more and more aware of its true nature. The thought censors do not enjoy an optimistic prognosis. In time they will be forced to give way altogether, for truth is on the march. All revolutions need not be political. Revolutions of the spirit of man are ever so much more drastic. The spheres of materialistic concepts ... money, power, war, possessions, and others, may still be in the forefront of man's interest and desire. But there is an irresistible motion toward a great and mighty goal ... a fulfillment. Tiny quantitative changes, all but imperceptible, will result in a tremendous qualitative leap .. total intellectual emancipation.

There is nothing so powerful as an idea which comes into its proper time. There is nothing so futile as an outworn principle, fighting against time and progress. Change is inevitible, and we are going to see many changes. There is a new world a-coming, a brave, new world of tomorrow. Those who refuse to change along with it are going to become extinct. It's just that simple.

... Dave Mann K2AGZ ■

Are Sub-bands Meaningful Today?

In the early days of amateur radio, when phone operation was first invented, it raised such hob with CW that it was split off into the higher parts of the bands, the frequencies that no one used much. This was just fine with the pioneer phone men because they didn't like those confounded CW signals in their phone band any more than the CW men wanted the mass of heterodynes that made up the phone bands.

By the 30's we had 100 khz on 20 and 75 meters for the Class A operators. Both bands generally were jammed up tight with about ten solid kilowatt signals. When one of these rock piles would go off you could hear ten weaker heterodynes coming through the gap from ten lower powered hopefuls. No wonder that about 90% of the activity was in the CW bands in those days.

Phone DX was worked outside of the American phone bands. Few DX stations had signals that could cut through the enormous heterodynes that filled our phone bands. In the good old AM days it took about two stations to have an unreadable pileup.

Then came sidebands and the layers of heterodynes gradually died away. We began to hear more and more DX operators working right in the American phone bands. Today most of the phone DX is worked in the American band, with the exception of an occasional backward DXpedition operator.

Now that AM is about gone from our DX bands, perhaps it is getting to be time to do away with the concept of separate American and foreign phone bands? For that matter, with the percentage of amateurs using CW growing smaller every year, perhaps the time is not far away when we will be able to do away with sub-bands entirely? I'd like to see it given a try for a while to see how it works out.

The present day CW op has filters available that can virtually remove sideband. The sideband op can virtually remove CW, if he uses a couple of notch filters. Our bands can hold many times the number of phone and CW signals that they could a few short years ago just because receivers have come such a long way.

I note that a group of amateurs is about to petition the FCC to open the phone bands for an extra 100 khz on 75-40-20 meters. Good plan, of course, but why not go all the way and open all frequencies to everyone? Instead of taking more and more frequencies away from the active operators, why not give them all more? Is there really that much harm to be done? We could try it for six months on one band and see what happens!

ARRL Board Meeting

The special November meeting was supposed to come up with recommendations for the FCC regarding incentive licensing frequency changes. Unfortunately the FCC didn't wait for the advice, so the Board found itself with a lot of little matters and no main topic. The 1970 national ARRL convention will be in Boston. Fine. I hope that 73 will be permitted to attend this one ... the last Boston National saw us excluded by personal directive of Huntoon.

The board agreed to petition the FCC to grant counterpart call letters to amateurs moving from one call area to another. I'm glad they did this. But I do wish that some interested ARRL member would buy a subscription to 73 for the directors so they would know that this petition has already been entered. I reported this in October on page 127 as RM-1455. If any one of the directors or the headquarters gang had read 73 they would have known that this had been done. A reading of the FCC actions would have also alerted them about this. I'll bet you'll never guess who sent in the petition to the FCC originally. Heh, heh!

... Wayne ■

0300	14.235	SSB to southern USA
0310	14.235	SSB to western USA

LETTERS

Dear Wayne,

Without question, your magazine is by far and away amateur radio's superior publication. In the September issue on P. 134 was a letter by Arthur Woods W4GJW in which he made many suggestions for new subject matter for your magazine. This I heartily endorse.

I would like to see owners reports of manufactured amateur gear such as those automobile owner reports in Popular Science, etc. Proper editing would bring out the strong and weak points or limitations of each piece under investigation. Simple modifications could be thrown in, if desired. The series would be self perpetuating by asking at the end of each article . . . Owners of the Super Whamee Mark IX (or whatever gear desired) please send your comments to 73 Magazine.

I am certain that a series of this kind would be successful as hams from around the world would feel that they are contributing in a small way to a fine publication as well as to amateur radio. I can't think of an easier way for amateurs to get involved.

Stan Pugh WA7KSC
2521 North Proctor
Tacoma WA 98406

Dear Wayne,

Been reading 73 now for several years–just like I read CQ when you were running the show there. Even met you once in San Antonio at the Gulf States Convention about fifteen years ago! So long?? Anyway, I have enjoyed the reading.

Like a lot of other hams I am also interested in making things that are not always for the ham-shack. Right now it is metal detectors. I'm wondering if there aren't a bunch of other readers who have the same interest. I would like to swap circuits if anyone wants to and I would particularly like to have a good BFO circuit using a crystal controlled oscillator on 100kc–like the unit made by White's Electronics in Oregon.

So how about it? Can someone do an article on the subject? Or just print this letter–maybe someone will come up with a good one.

Les Spoonts W5WWX

Arlington TX 76010

Dear Wayne:

In the ". . .de W2NSD/1" portion of your issue for November, at p. 126, I seem to read an echo of my letter of March 7, 1969 to you–under Public Relations. I do understand that QST has now retained a PR consultant, or some such. Hope the rumor is correct, or that it at least indicates a change of attitude.

Hopefully, this may all lead to some constructive effort to lobby *for* amateur radio in Washington. Too often I have found that PR work, per se, merely serves to lock the barn after the horse has been stolen. Your very pertinent remarks concerning the obvious results of the implementation of Docket 15928 seem to me to show pretty clearly that horse, barn, and most of the crops are long gone.

Of course all of this, involving frequencies, spectrum utilization and amateur population are matters that many of us brought to the attention of ARRL and FCC when 15928 was first weaned. That our protests were very generally ignored must by now be accepted and recognized as a great disservice to amateur radio by those whose declared reason for being was the orderly and constructive development of the hobby, art, service or whatever one likes to call it.

I can remember when very few amateurs had a good word for that hot-headed radical, W2NSD. I suspect that if a poll were taken today you would be considered something of a dedicated prophet! Some miles northwest of you there is, in Hanover, a college that has the motto–"Vox Clamantis In Deserto," or something like that. My recollection is that it means something along the lines of "A Voice Crying In The Wilderness."

It must be so with you. It can only be hoped that in some way the larger body of amateurs will really listen to what you have to say, and will give tangible support to a movement towards a sane and constructive program to give vitality and purpose to the amateur game.

Al Smith W2AFJ/K3ZMS
Penury Priory
Doylestown PA 18901

Dear Wayne,

I sure do like your magazine and its unbiased (?) opinions. What I really wrote about, however, was to enlist the services of anyone who knows the "magic trick': how to use the Central Electronics 10B as an SSB exciter with the Heath TX1 Apache transmitter. Also, any teens or Novices wish to start a net on 15m? Please contact me.

Gregg Marco WN6IZT
2880 Ridgeway
San Bruno CA 94066

Dear Wayne,

The reason everyone is so interested in "sex, religion and politics' may be that most amateurs are far behind the professional world in technical matters.

The biggest problem seems to be that manufacturers of components gear themselves for industry not the individual amateur. There are integrated circuits that contain an i-f amplifier, and detector including AGC. Another IC for the audio, a third for the rf, add a couple tuning coils and a speaker and you have built a high performance portable receiver. With the manufacturer's data sheets, you don't even have to know how a transistor works to have a good time building.

But there is the problem: How does the average ham find out about the latest circuits? The only way seems to be to read trade magazines and write for data sheets. Either that, or wait until some other ham does so and writes an article for 73.

What we need is more information on these new devices so hams need only read amateur magazines to keep up to date. Maybe the ultimate would be a special ' newsletter" for amateurs only.

What say?

Paul Zander WA8JCM/9
25-5 Ross Ade Dr.
W. Lafayette IN

Dear Mr. Green;

It is seen that the growth of 73 Magazine is like that of the field in which you are dedicated. This may seem to you as a way of saying congratulations to you and your staff for this is true.

It is with great sadness that it is easy to see that there are those who cannot see that the use of that which is called, telegraphy, is that which cannot serve the growth of the nation. There was a time when the state of the art was such that telegraphy was all there was. When we see the advancements which are known to us today, we see that telegraphy is not responsible for these advancements. We see that these advancements would not have been possible had it not been for those who saw that telegraphy can never serve in the successes of the electronic control systems of all kinds which were used for positive control in the automatic control of the space program and in industry as well. High speed Teletype has replaced telegraphy. All of this gives more work for many more people in a growing country in the sense that electronic technicians far outnumber the few remaining telegraph operators.

In the public view, the repair of an electronic device or a television set requires a technician. In the public view, the public does not look for a telegraph operator to repair a television set or any of the electronic devices which the public uses and/or enjoys. This is to say, telegraphy is not important to the public.

When we see this, we see that the public will never be convinced that telegraphy can serve them in their needs. Their needs are not that which telegraphy represents. In the public interest, telegraphy is not known nor is it needed.

Telegraphy is like a man who lost one leg. He cannot walk as can a man who has both of his legs. The previous paragraphs explain this in other words.

It is seen that there are those who seem to believe that telegraphy is needed in order to prove that a technician is not a technician unless the technician knows telegraphy. We all know that this is not true for we see that a knowledge of telegraphy can never repair a television set or any electronic device used in the public interest. This clearly tells one, there is no need for telegraphy in industry and commerce of a nation. It is seen that this is true.

When we see that the military services have been abandoning telegraphy for more exotic means of communication, it is seen that the military services recognize the fact that their only use of telegraphy is in battle. Even here we find that the military frequently uses equipment which is not designed for telegraphy in the sense that voice commands are more quickly understood. We refer here to armies committed in battle and each knows the others position. We find that there is no time to be lost in these conditions. This is to say, not even telegraphy serves here.

It is seen that there are those who believe or who seem to believe that it is necessary to provide a limit or to limit the number of radio amateurs in the belief that telegraphy is the means which they see as being effective. The manner in which this has been done in the division of the bands is seen as that which the Government of the United States cannot do in the sense that the Government cannot discriminate. It is seen clearly that this division discriminates against some and in favor of others.

BACK ISSUE GUNSMOKE !

30, count 'em 30, stupendous tremendous (more handbooks than magazines) fascinating enormous devastating incredibly enervating back issues of 73.....

ONLY $5.00
postpaid worldwide

Yes...yes...yes...here is a golden opportunity to blow your mind on 30 back issues of 73. You send us $5 in negotiable securities, cash or check and we will send you an unbelievable miscellany of thirty different (all different) back issues, all from the 1960-1966 era. These are all rare collectors items. Every one could likely be worth a fortune to you. Who knows, you might even find a rare January 1961 in this pile! We don't even know what is in these packages. To keep costs down we have had these magazines packed into sloppy bundles by the Chimps from Benson's Wild Animal Farm (nearby). Watch out for banana skins. —If you want specific issues of 73 they are available at the low low (high) price of $1 each. Unless we don't have them, in which case the price is higher. —How about sending a bundle to a DX friend? Back issues of 73 are worth their weight in unicorn dung in most countries. —Money received without a shipping address will be used for beer.

TOWER COMMUNICATIONS
1220-22 Villa St:, Racine, WI 53403

This is to say that the Government is not an individual who can select his or her own friends.

The selection of one's own friends results from common interests or common desires. Electronic theory is not easy to learn and is never fully learned. Those who know electronics are those who know this to be true. Those who do not know electronics find that for them it is not that which interests them. This can be said of any profession. The practice of medicine is an example of this.

It can be seen that the interest in electronics is that which has given and will continue to give more technological advancements which are in the public interest. It can be seen that the amateur bands have provided the radio amateur with the means by which he does develop a technical skill which industry needs and which industry does not provide. Industry wants a man already trained. It can be seen that were there to be no amateur bands there would be no developments in industry. It is the radio amateur who has been responsible for the technological advancements.

Industry requires men who are trained in all of those fields which are available to the radio amateur who is a technician. The only reward for a radio amateur is a greater knowledge which he has gained.

Mr. Lin Carol
Avenida Cometas 180-B
Colonia Contry
Monterrey N.L. Mexico

Dear Mr. Green,

I have been subscribing to "73" for several years, and I think it is getting better with each issue. I wish to add my thanks for the Advanced and Extra Study articles. They are much clearer than many other study guides, and contributed greatly to my getting the Advanced ticket. My code speed is improving gradually, and I will have the Extra one of these days.

I hope you will allow me to comment on some of the issues which you and others have raised in letters and articles which you print. First, I disagree with W1DIS's opinions (page 40, Nov. issue) on what can be discussed on the air. There is nothing in FCC regulations which says we cannot use the ham bands for an open forum. For those who have not read it or cannot find their copy, subpart E of FCC amateur regulations says ONLY that, "NO LICENSED RADIO OPERATOR OR OTHER PERSON SHALL TRANSMIT COMMUNICATIONS CONTAINING OBSCENE, INDECENT, OR PROFANE WORDS, LANGUAGE, OR MEANING." (Par. 97.119 FCC regulations). I have gone over these regulations time after time and nowhere can I find any other mention of what we can or cannot talk about. In other words, I believe the FCC gives us the benefit of the doubt that we will conduct ourselves on the air with common, ordinary decency, and if we do otherwise as stated in Par. 97.119, we can expect our tickets to be suspended. I will, therefore, discuss any subject with anyone in as gentlemenly a manner as I know how, but will break off or refrain from such a discussion if it becomes ungentlemenly!

I do not agree with those who are fussing about the difficulty of the license exams. The FCC uses only 98 words to describe the basis and purpose of Amateur Radio, (Part 97.1), and these words include the following; ". . .provide emergency communications; . . .advancement of the radio art;

. . .rules which provide for advancing skills, . . .trained operators, technicians, . . .". An old timer told me many times that anyone can learn the code and can increase his speed if he is willing to practice, so those who gripe about it are just plain lazy. The FCC provides the Citizens Band Radio Service for those who do not care about advancing their skills or improving themselves as a trained operator.

For those who do not like the present incentive licensing program, I suggest they write the ARRL and also write the FCC even if it takes 14 copies. Here are my suggestions for a better incentive licensing program, and I have written my ARRL director, and intend to write FCC also:

1. Drop Advanced Class license.

2. Restore to Generals the frequencies allowed prior to Nov 22, 1968, in the interest of public service.

3. Allow Extras to use phone in what is now known as the "Foreign" phone segments.

4. All licenses except EXTRA class, should be non-renewable. Conditional should be for only one 5 year period except for disabled with doctor's certificate stating inability to travel. Anyone else should be able to find his way to an FCC office or field examiner sometime in 5 years.

I can hear the moans and groans about having to take a new exam every 5 years, but how else can we fulfill the basis and purpose of Amateur Radio if we don't upgrade ourselves? I hope you will print this letter to get some reactions, and also maybe it will stimulate some more thinking on how to improve the situation.

J. W. Harrison, Jr. WB4TBX
1234 Little Bay Avenue
Norfolk VA 23503

Dear Editor:

I am writing to commend author R.J. Zach and the editors of 73 Magazine for the series of articles on FM. We are in favor of any means of furthering the cause and have noted that several articles on the subject have been recently published.

I have noticed, however, that only one of the many articles published (Bill Orr's in Ham Radio) even mentioned the existence and availability of any new equipment made for the amateur market. I think it only fair that some mention of this new equipment should be made–not only of the Varitronics-Inoue line, but also of several other manufacturer's equipment–so that your readers will know that used gear is not the only thing available.

I am enclosing specification sheets on our current models for your information. Again, thanks to you and the editors for furthering the FM cause.

Sharon LaTraille
Vice President
Varitronics, Inc.

See editorial "VHF FM: A New Involvement" and "Low-Cost Electronics: Japan's FM Invasion," this issue. . .ed.

Wayne Green:

I have subscribed to 73 for four years, now, and it IS the best that I have read. I also subscribe to Ham Radio, QST and CQ, so I think that I have all the numbers covered. 73 Magazine, in my opinion, gives me the greatest pleasure of them all and I shall stay a very satisfied one–till death due us part, or something. I passed the Advanced without

MIN ORDER $5.00 FOB Binghamton

your help—no sarcasm intended, and would pass the Extra—if you could get the FCC to lower the CW to 15 wpm. What is this—proficiency in CW or theory? Of course, as you have surmised, I am excellent on theory and lousy on CW, but I am honest. I am writing like mad to QST and directors, to forget the second half of this incentive thing, which, I am Afraid, will kill or set back Am. Rad. Anyway, good luck to you.

Jack Golden WA2YPW
Portville NY 14770

Dear Wayne:

There are occasions upon which I wish you would base your writings upon fact.

On page 127, November 73, you state that I publish two magazines on a commercial basis complete with ads and subscriptions. I do not *publish* any magazines whatever. I do *print* three. The Auto-Call is published by the Foundation for Amateur Radio, of Washington, D.C., a fact which can be determined from the address side of any issue. The DARA Bulletin is published by the Detroit Amateur Radio Association. The ARNS Bulletin (surely you're not accusing this one of being commercial?) is published by the Amateur Radio News Service. Each of these is printed in my basement on the basis of materials cost only without any charge or retainer whatsoever for labor or machine depreciation. Each publisher receives, directly, all money for subscriptions, advertisements or dues and any profit (or loss) accrues directly to them, not me.

I am gratified that you are concerned about the time I spend in printing these publications, but I can assure you that only a small portion of my time is involved in the printing.

Since you are now set up for printing (page 129) I would be most happy to turn the entire affair over to you, providing you will do the work at the same price.

For your information complete financial details of my entire operation were furnished the members of the Executive Committee of the ARRL who passed on my eligibility for Vice-Director, and who adhered strictly to the provisions of Article 12.

I insist that you print this letter in its entirety as a correction to your statements.

Ralph V. Anderson KØNL
Vice-Director
Mid-West Division, ARRL

My Oxford Universal Dictionary defines a publisher as, "One whose business is the issuing of books, periodicals, music, etc., as the agent of the author or owner; one who produces copies of such works, and distributes them to the booksellers and other dealers, or to the public." The dictionary says nothing about profit. You admit in your letter that you are issuing periodicals and distributing them to the public and this makes you a publisher, whether you or the Executive Committee like to call it that or not. Article 12 has been violated, obviously. . .Wayne.

Dear Mr. Green,

Mr. Hartley's recent article ' Religion, Politics or Sex' has raised two basic ideas:

1. Why can't amateur radio be a forum for exchange of ideas? There is nothing wrong with calmly discussing politics, where a real dialogue exists and ideas and ideals are exchanged and expressed. People who object to one's ideas must

either learn to accept other's ideas or change frequency.

2. To preserve our society, we all must learn to accept each other's ideas, and accept his right to say his ideas any time and anywhere he wishes. (If he breaks the rules, he must be punished, however.)

It is ironic that we have the fantastic communication capability, but we have nothing of any value to say to each other.

James Altman WA0UWL
1921 Pinehurst
St. Paul MN 55116

ADDENDA & ERRATA

APOLLO TV & RADIO (Nov. 73) Addenda: An adjustment should be made for Westinghouse Electric Corporation and Radio Corporation of America as follows. The monochrome TV camera used on the Apollo 7 and 8 space missions was made by RCA, as stated. However, the monochrome TV camera used on Apollo 11, which was left on the lunar surface, and the monochrome TV camera used on Apollo 9 was made by Westinghouse as well as the color TV cameras for Apollo 10 and 11. The statement to the effect that the RCA camera was utilized in Apollo 11 and 9 was based on incorrect information. I am thankful for being corrected.

Thomas Laffin W1FJE
Hillsboro NH 03244

Dear Wayne:

The error on page 76 of the November issue of 73 should read: "This is possible if we assume that the dc current gain hFE is much greater than one, and that the collector current is very nearly equal to the emitter current." This is because the high hFE makes the base current much much smaller than the collector current. Recall that the emitter current precisely equals the collector current plus the base current.

I have received letters, but I was surprised to receive a couple of long distance phone calls. Letters are fine because it gives me time to sit down with the magazine and work out an intelligent answer, but a phone call catches me suddenly without a chance to think, and I usually can't give an answer right off.

Cliff Klinert WB6BIH

Ham Tips: More Uses for Bx Armor

When running antenna leads from the roof to the house, it is almost impossible to avoid subjecting the cable to abrasion from either the building or the roof edge. In time, this abrasive action will cause the wire to fray, and then break.

A section of Bx armor, placed at the point of stress, and securely taped in place will guard against the effects of abrasion and insure that the antenna cables you put up in June will still work well in December.

The Combo

Most amateurs cannot send good CW unless they monitor what they send, and few have come up with a monitor which satisfies them. Here is one that won't win any ribbons, but it will do a good job and with perfect reproduction. It doesn't think for itself, so you must control it as it will key the transmitter exactly as you send.

The circuit is very simple; a single PNP audio transistor in a common base configuration. All parts except the relay and choke came from a discarded transistor radio. It will work well with any general purpose audio transistor and an NPN may be used by reversing the battery polarity. The key acts as the oscillator switch, and switch SW controls the keyer.

Be sure that the choke is placed directly at the relay points and short the contacts with a small by-pass condenser at the point marked X, keeping the leads as short as possible. This will eliminate chirp and key clicks.

The relay can be any very small make and break type that will operate at the battery voltages and must draw very little current or the battery will not last long. Make sure the relay will work at the speeds you operate, and that it does not chatter.

The entire unit can be housed in a small black plastic meter case (3½x6x2 inches) available from Lafayette for about 75 cents. It has enough spare room to house a small power supply should you desire to include one.

The keyer will key any type transmitter as long as the relay contacts will stand the current and it will need no reverse blocking diodes.

The ten K pot is a tone control and resistance is not critical and may be changed to suit taste.

The keyer requires no practice to learn to use and can be built for a few dollars at most. It is just the thing to tuck in your pocket for Code Practice at Scout or club meetings.

Ham Hospitality

Dear Wayne, OM

We have just received our June issue of 73 Magazine. Big deal, but this was relatively fast, as many issues arrive 3 to 4 months late, due to the mail service here.

I note that on page 119 your article about hospitality for hams. Since we have been here in Brazil for over five years, and speak the language fluently, perhaps we can assist any hams who may wish to visit Brazil. We would be delighted to have a "casal," couple stay with us in our home, and I (the XYL) would be glad to take any XYL shopping, while the OM made visits to other localities, such as our kinescope factory, record factory and if they wish to buy precious stones in the state of Minas Gerais (where we have our receiving tube factory), I can assist them there also. We lived in that state for over three years, and I have learned quite a lot about stones.

Just remember that this country is large, and Recife (where some people visit) is about 1000 miles away, HI! Any one coming to Sao Paulo is more than welcomed. Our home phone number is 62-4530.

Continue to work hard, but at the same time enjoy your work! As yet Brazil does not have reciprocal licensing so we are not on the air, but we know many hams here who are always anxious to meet American hams.

Let us hear from you!

Frances L. Gunther-Mohr

EDITORIAL BY WAYNE GREEN

Crowded Bands

If you, too, have been involved with amateur radio for some thirty years, I think you'll have to agree with me that one of the big all-time complaints has been QRM. Even those with sixty years of hamming under their belts will tell you that from the first day of their operating, QRM was murder.

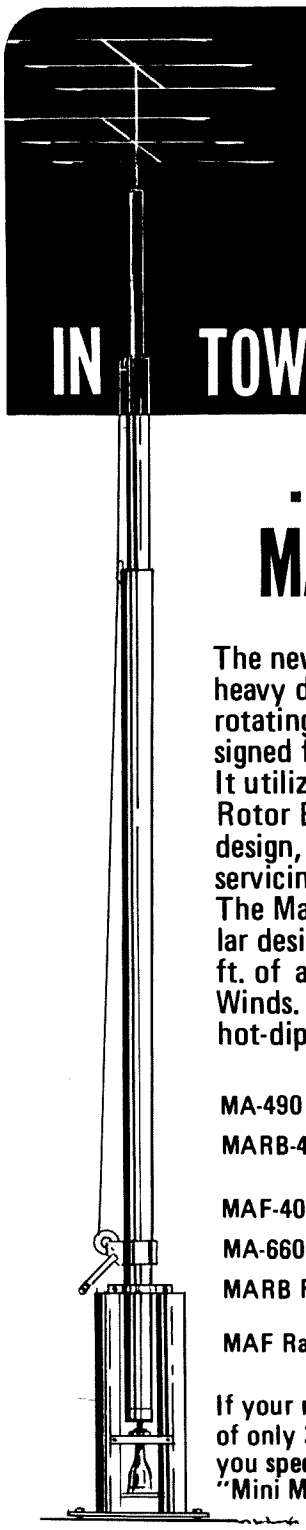
Since, in practical application, QRM can be largely avoided, I suspect that most of the true sufferers from the condition are masochists, unduly stubborn, or perhaps just not too swift. At one time in our history amateur radio was rather well known to the general public, though the image they had was one of young boys staying up all night in attics. I'm not sure that even that image is better than not having one at all, which is about the shape we're in these days.

Green's Law

If you insist on forcing amateur radio to fit your convenience, you may be a sufferer from QRM. The evening hours and weekends are the most convenient, so that obviously is when there are the most stations on the air . . . and the most QRM. These are prime times for developing a mental hernia trying to get a short ragchew on 20-40-80. Meanwhile, up on 2 and 6 meters, this heady peak of activity will, in many parts of the country, give you a choice of two stations to contact instead of one. Green's QRM Law No. 1 (an extension of the Finagle Principle) tells us that if there are just two contacts on a band, they will probably be just about on the same frequency and will be QRM'ing each other.

The RTTY gang can be heard typing up a storm with little interference, and, lonely of the lonely, the Extra Class CW ops can be heard during peak operating hours all huddled near one frequency down in their exclusive bands.

If you are too stubborn to head for the wide open spaces of 2 or 6 meters, don't dig typing out your contacts, and don't cotton to the untrammeled higher frequencies on 10 meters, then perhaps you could bend to the extent of changing your operating hours a bit? I may be ruining a perfectly good thing for myself by telling you about this, but the bands are almost empty in the early mornings. That's when you'll hear *me* operating.



Generally I'm in bed by 10 p.m., which means that along about 4 a.m. or so my eyes open up and I either lie there staring at the ceiling or else get up, get dressed, and head for the office, a twisty 10-mile drive through the New Hampshire hills. After fixing a quick breakfast I head for the rig and see what is doing. The signals are few, but the band is most certainly open and the contacts are generally free of QRM. In winter I can usually work just about anyone who happens to be on the air in Asia, the Pacific, South America, Antarctica, and even Europe.

Don't Follow the Pack

A little trick I learned the hard way nets me a lot more DX than the average operator. Now and then you will hear me in a pileup, but most of the time you'll hear me *starting* pileups, not continuing them.

After listening to the gangs of operators trying to get through to rare spots, you may get the erroneous idea that the op in the rare spot has it easy—any time he gets on he is loaded with fellows trying to contact him. It doesn't work that way. This fellow has a good deal of frustration because he is in an out-of-the-way spot.

The problem is that when Europe is coming through to the States, almost every beam is pointed at Europe. The fellow down on a small Caribbean island can call his fool head off and no one will hear him. I remember one particularly frustrating time. I had just received my license to operate as VR2FD in the Fiji Islands and I fired up on 20 sideband. The band was hopping . . . this was going to be fun. I heard Dorothy K2MGE in a roundtable with some other friends and I called in. Nothing. I tried breaking. Nothing. After a half hour of trying to break between every leg of the roundtable, I heard Dorothy say she thought she heard someone trying to break the QSO. My relief was short-lived. The next station came on and dismissed me with the remark that whoever was trying to break in was not cutting the mustard. They never did stand by for me. I tried up and down the band for another hour, calling CQ, answering CQs and trying to break in on friends. The VRs that were in the shack with me explained that it is always like that. Everyone has his beam pointed toward Europe and there is little chance of getting through.

A SPACE AGE CONCEPT IN TOWER DESIGN

...TRISTAO'S MAGNA MAST

The new Magna Mast is a heavy duty self supporting, rotating crank-up mast designed for ease of installation. It utilizes the new Tristao Rotor Base with swing over design, permitting antenna servicing at ground level. The Magna Mast's clean tubular design will support 12 sq. ft. of antenna in 60 MPH Winds. Its finish is entirely hot-dipped galvanized.

MA-490 49' Magna Mast	$389.95
MARB-40 Rotor base (rotor not included)	$109.95
MAF-40 Raising fixture	$59.95
MA-660 66' Magna Mast	$799.95
MARB Rotor base (rotor not included)	$199.95
MAF Raising fixture	$119.95

If your requirement is for a tower of only 30 or 35 feet let us send you specs and prices on Tristao's "Mini Mast". It's a little beauty.

Henry Radio

11240 W. Olympic Blvd., Los Angeles, Calif. 90064 213/477-6701
931 N. Euclid, Anaheim, Calif. 92801 714/722-9200
Butler, Missouri 64730 816/679-3127

Eventually I snagged a KH6 and a couple of the more alert W6s heard the contact. Suddenly there was a pileup and I was busy handing out contacts as fast as I could. You could almost hear the rumble of a thousand beams turning all over the U.S.

Now, when I get on the air from home, I seldom point my beam along with the crowd. If they are working Europe I swing my beam around and call a CQ toward Asia or the Pacific. If they are working the Pacific, then I call for the Indian Ocean or the Mid-East. These directional CQs work for me. Just yesterday I contacted VK6GK mobile (VK6 is the antipodes from up here), 9V1OH, and VU2GE. The VU was running 15W of SSB, by the way. More often than not, a directional CQ like that will bring in something rare, giving you a contact that you otherwise might have to spend hours working for, fighting the pileups.

. . . Wayne

Gentlemen:

With regard to your Christmas photo in the December issue:

We've looked at the picture–examined the scene,
Which is quite reminiscent of Mad magazine.

We've paid close attention and Lin Green looks nice,
And so does Dot Gibson–ditto Phil Price.

Walt Manek looks sad through a grin that's excessive.
Is that what you call a Manek depressive?

Horray for Diane who in mini looks racy
And hello there to Roger and Don and Jane Tracey.

Hi, to Joe, Jeanne and Wayne–the rest of the cast–
And now for the best which we've saved for the last.

Your gang sure appears like a fun-loving group
And we quite hate to throw an old fly in the soup

But all through the years, in hamming, in life,
In all of the good times, and all of the strife

Past all tribulations–past winnings and losings
Past days being sober, and days filled with boozings,

You can torture us, mangle us, freeze us or fry us–
There *can't* be a girl named Whitney Tobias!!

Jules E. Blitz
7934 Winterset Ave
Pikesville MD 21208

Dear Reader Jules: much thanks for your poem.
It has spiced up the air at our magazine's home.
As to your comments about Lin and Dot,
We agree with you fully–they said "Thanks a lot."
Phil Price thought it funny–he shed a small tear,
And our Manek depressive is no longer here.

As for Diane, well she accepts, with a wink,
And Roger and Jane say "Hi, Jules," I think.
Our Joe and our Jeanne send 73's,
And Wayne, our big chief, completely agrees.

Yes, we are a fine bunch, and we do have much fun,
But your fly in the soup is such a bad pun.
For in truth and in friendship (I'm not being pious),
There is truly *a girl named Whitney Tobias.*

. . .Diane Shaw

AN
EDITORIAL
BY K6MVH
KEN SESSIONS, JR.

Why This Issue of 73 is Dedicated to WA8UTB

This is an obituary.

An entity that lived fast and hard and well has passed. This living thing was FM Magazine. For me it was a promise unfulfilled. For Mike Van Den Branden it was a dream turned nightmare. For a world of new people–the repeater men, the two-way hams, the FM pioneers–the death of FM Magazine was the loss of something that was uniquely their own.

Mike Van Den Branden WA8UTB was the originator of the magazine, back in February 1967. He put out a sheaf of duplicated papers and called it FM Bulletin. Everything seemed right. There was a general turning to FM on our VHF amateur bands that was to grow beyond everyone's belief. And the Bulletin was to become the widely approved and unanimously accepted voice of this new and expanding group.

Matching the contagious popularity of the mode, the publication expanded too . . . until it seemed the bulletin-turned-magazine would bust apart. It went from duplication to lithography. And within months it was a well dressed slick with four-color cover and professionally prepared interior that could stand abreast with the best of the well established old-time pros.

I was editor of this magazine, and shared the ownership with Mike until it nearly broke my back. When I gave up, he carried on, assuming responsibility for a financial burden that would make Rockefeller cough.

Oddly, Mike Van Den Branden was not in the publication business for the money. He was one of those rare, one-in-a-lifetime types who follow a dream because of the dream. Mike believed in FM as a communications mode. And he believed his magazine filled a definite need. This is not to say that Mike would not have been pleased to see his "baby" turn a profit; but he was not once discouraged by the fact that it never did.

And Mike was always willing to bear the financial brunt of new ways by which his baby could be improved. If you happen to be one of the very very few fortunates who have a complete library of FM, you know the metamorphoses that characterized the 3-year lifespan of FM Magazine.

This is the end of the obituary of FM Magazine. But it by no means marks the end of the Mike Van Den Brandens. So maybe a toast is in order:

Here's to the dreamers.

Buffalo Hams Influence Rulemaking in Canada

The members of the Buffalo Amateur Repeater Association are to be congratulated; for these individuals, who spent many long and arduous hours drafting a detailed and comprehensive petition to the FCC concerning the operation of repeaters in the VHF amateur bands, have achieved at least a degree of success. The efforts of Gil Boelke W2EUP, Francis Stengel WB2GUG, and a handful of others of the BARA organization have not gone unnoticed. Some time ago, Canada's regulatory agency, the Department of Communications, sought guidance in laying out a plan of rules for prospective Canadian repeater licensees. Using the Buffalo petition as a foundation from which a set of realistic regulations could evolve, the DOC recently published a tentative mandate that will

serve as "interim regulations" until such time as permanent rules for amateur repeaters are passed into law.

Of the mandate's seven points, at least four had been put forth in the famed Buffalo petition, and several of the others were unofficially advocated by BARA representatives in letters drafted after the petition was originally filed.

The points of significance to repeater owners are:

- Licensee will be responsible for TECHNICAL operation of the repeater, including ultimate control over any amateur's access (or the access of a restricted group).
- Licensee will maintain a TECHNICAL log showing malfunctions, servicing data, on-the-air tests, etc. (This precludes the necessity for running a continuous tape log of operation, presumably, and is the essence of the Buffalo petition.)
- Repeaters will identify at one-minute intervals by transmission of the repeater call sign at reduced amplitude.
- Links are to be in the frequency range above 220 MHz, but they are exempt from the aforementioned identification requirement.
- The licensee is required to put a three-minute automatic shutdown transmitter on each of his remotely controlled transmitters. And it must be rigged in such a way that only the licensee can turn the transmitters on again once they are shut down.

These rules are a step in the right direction, and they serve to show that the Canadian government is on its toes with respect to what's happening in the amateur world there. But there is one aspect of the rules that has frightful implications. I can only hope it is a mistake in wording, because it can serve no useful function of itself and can only result in making repeaters in Canada less utilitarian for the many users.

The rule I am referring to, of course, is the last one cited above. The mandate specifically states that when a repeater is timed out at the end of a three-minute period, it must be reenergized by the licensee only. In practice, virtually all repeaters–both in the U.S. and in Canada–are already equipped with such timers; when an incoming transmission exceeds a duration of three minutes, the repeater (and usually the links) shuts down. But reactivation is typically automatic; that is, when the longwinded individual drops his carrier, the repeater can be energized again by the next incoming signal.

Ostensibly, the Canadian ruling was put forth to assure technical control under all conditions. But the DOC should be made aware that such control could be assured in a variety of other ways, nearly any of which would result in a more useful, reliable system. For example, the licensee could transmit a control signal that would positively (rather than passively) shut down the transmitter when such shutdown is warranted. Or he–or anyone else using the repeater–could keep the system shut down by transmitting a continuous low-power carrier on the input frequency until positive control was effected.

There are a variety of means for achieving the same end. But the finality of automatic timeout suggested by the mandate does not seem to be in the best interest of the amateurs who will depend on the reliability and dependability of a repeater that will frequently be shut down by individuals who can't seem to turn themselves off after 2.999999 minutes of talking.

An interesting sidenote: QST published a short note about the Canadian doings in the December issue. Several ARRL directors were credited, but there was no mention of the effort expended by the Buffalo group. I consider this a bit odd, considering the fact that the ARRL has had a copy of the Buffalo petition since the time it was filed, back in 1967.

Repeater Petition to Get Docket Number

A repeater rulemaking petition was submitted to the FCC on December 3, 1969, and is currently undergoing processing so that a docket number can be assigned. The petition is too lengthy for reprinting here, but here is the essence of it:

1. An amateur repeater is officially recognized and defined.
2. Repeaters to be made legal on all frequencies where AØ is authorized.
3. Timed shutdown is required after long non-use periods.
4. Repeaters can be turned on from the frequency of operation provided that UHF control is capable of overriding such turn-on, when necessary.
5. Repeaters can be "unattended," since shutdown is automatic when repeater is not used. It can thus be assumed that the repeater is being monitored (from the frequency of actual use) when it is on. The petition seeks to dispense with "UHF control" monitoring in favor of the "on-when-used, off-when-not-used" approach, which is essentially "unattended" operation, but with a realistic and workable twist.
6. Repeaters should not be logged in the conventional sense. A log would consist of a few basic particulars and would be filled in only when the remote repeater is visited, serviced, or modified.
7. Repeaters should be identified at 3-minute intervals, and the ID can be nothing more than the repeater call letters, in Morse code or voice.

(continued on next page)

There are more than 300 FM REPEATERS in the U.S...

...WANT TO GET IN ON THE ACTION?

STELLAR HAS THE NEW GALAXY

$199.95

It's a 3-channel mobile unit with a full 5 watts of transistor power to assure you of "making it" even through the repeater's "dead spots." . . .The perfect driver for that final on the hill!

The SAROC Funfest

In case it's slipped your mind, time is running out for those of you who haven't made advance reservations for SAROC, the Stardust Amateur Radio Operators' Convention, to be held on February 4 - 8 at the Stardust Hotel in Las Vegas. The SAROC funfest has been getting bigger by the year, and indications to date are that this year will top all previous records.

For the nonteetotaling among you, SAROC will offer a number of advantages for you to mooch free booze; cocktail parties are being hosted by the magnanimous managements of Swan, Galaxy, and Ham Radio.

National FM Convention. Ham FM'ers should take particular note because SAROC serves as an operating base for the annual national FM convention. Tom Burford W7TDQ is the principal representative for the FM portion of the shindig; and if you drop him a card, he can give you the details on the FM programs slated for this year (which, incidentally, marks the third annual national FM convention to be held in conjunction with SAROC). Tom's address is 6328 Shawnee Ave., Las Vegas.

At this writing I have no idea as to what the agenda is, but I can guarantee that it will be interesting. Last year, a national repeater group was formed, and national repeater frequencies were adopted. There were a few disappointing problems associated with FM scheduling last year, but most of these were attributable to apathy on the part of the hotel management. Switching of SAROC from its previous base to the Stardust has solved these potential headaches, I hear.

If you have gripes about 73 or its policies, or if you have pet circuits you want to see printed, grab me at SAROC. I won't be hard to spot; just look for the guy who has the "special deal" on subscriptions.

Reservations. If you don't know how to get your reservations or how much money the affair will cost, send SASE to SAROC, Box 73, Boulder City, NV 89005. You'll get the details back fast.

. . . K6MVH ■

Hospitality Notes

Dear Friend,

I am very interested in your Ham Hospitality scheme and hereby offer my home for any visiting hams, especially Stateside DX.

My interests are ham radio, organ music, and politics (I am a City Counselor, Johannesburg). XYL is 45 years old. Her interests are cooking, garden, stamps and politics. We have two delightful dogs (our children are married and live elsewhere) and, apart from two full-time servants, we live alone.

This offer is made in all sincerity–no strings attached. Visitors and their children would be made very welcome. We love having guests and would be offended if any offer of payment is made. Reciprocity one day is all we expect. Are there any California hams who could house Corrie and self over December 1970? I would like to write to them.

Dan Mahony ZS6OS
PO Box 1729
Johannesburg, S. Africa

Study Courses

Dear Wayne:

I hold an Advance ticket, Wayne–thanks to your very fine recent series devoted to helping amateurs climb the ladder. The exam–which I took and passed last week–was a cinch, only because I *understood* every question and could answer all with equal comprehension. Any amateur who feels he can pass the Advance exam by memorizing the ARRL license manual is fooling himself. It just won't work. Incidently, your November editorial correctly observed that the emphasis is now on SSB and transistors. It should be. Needless to say, I have accumulated and digested your Extra lessons, and this exam, too, I expect to be a breeze (thanks to your very fine handling of the material). My only problem is my code speed, which I hope to bring up to 25 wpm.

Charles J. Vlahos WB2ICV
Managing Editor
Plant Operating Management
205 East 42nd St.

TVI Case

To the editor:

The other day I spent some time at a friend's house, and as I was leaving I borrowed five or six copies of 73. When I reached home I sat down to glance through this magazine and ended up devouring one issue. It was sheer pleasure to sit down and read interesting material, page after page. As you can tell, I am sold on 73.

I believe now is the time to express an opinion and ask a question. First the opinion.

In your February 69 issue of 73, on page 36, is an article "$1,000,000 TVI Suit Filed." I read this through twice and wondered if 73 was the only amateur magazine interested enough to speak out. I found five issues of QST, for the months of February, March, April, May, and June 1969. I could not find one word about this "amateur world" law suit.

Now for the question. Would you please inform me of the outcome of this case, and does Grid W4GJO have the backing of the amateur population? I hope that this will not pose too much of a problem, but I am interested, as all hams should be.

I wonder why, after two years of QST, I never wrote a letter; but after one weekend of 73 magazine, here I am.

Daniel G. Willis, SSgt, USAF
CT2AS/WA2BDA
Box 183, 1605 CAMS
APO New York 09406

As a result of the exposure accorded the case in 73, the defendant has received assistance from a number of sources: From the ARRL, he received (without strings attached) a mimeographed list of suits involving tower cases; and from fellow amateurs, he has received a great many cash donations, which have been used to assist him in paying for the burdensome legal fees. Grid Gridley W4GJO, the defendant, tells us he is extremely grateful for the publicity in 73 and the support from within our fraternity. He reports that the suit has been dropped under a mutual agreement.

Self-Appraisal

Dear Mr. Green:

Having just gotten my October issue of 73 and having just read the letters column I want to make my opinion heard. We want to encourage new blood in the hobby. Introducing new people to the phone bands is most certainly not the way to do it.

We want to show them our better side. But the question is, what is our better side? I have yet to find the better side of ham radio (better side in my eyes). The phone bands are made up of hams that couldn't copy 3 words a minute of code, discourteous people, old people that scorn the "new breed" of appliance ops, and young people, who scorn the oldtimer–a lot of good ops and fine personalities. The CW bands are made up of dead segments where you can call for hours without a contact, segments so crowded that no one can copy anyone, and you have essentially the same crowd thinking much the same way as phone men with either the man thinking about getting one of those higher grade licenses and trying to get up his code speed, or you have the group that think the phone men are all lids that can't copy a word of code and are only slightly better than CB'ers.

The lure for many newcomers is the old farce of communicating with amateurs in foreign countries. In two years I have had calls from 18 countries. But I haven't *communicated* with them. I've communicated with three countries (one was an American working in a foreign embassy). I started in ham radio to find out what it is *really* like in Iron Curtain countries. Oh, you can talk to these countries. You usually have a long QSO of maybe 30 seconds if someone isn't continually tuning up on you. Some people are lucky enough to be able to communicate with foreign stations. They are usually the ones with 2 kW linears, big multielement beams on tall towers, with expensive gear.

And we really expect to compete with CB and SWLing? W4PZS is certainly correct in saying "they have divided the amateurs." They pushed incentive licensing through, even though there was much opposition (and much more apathy).

I am having much trouble saying exactly what I mean. Just the same, I think amateur radio is awfully lucky to get any newcomers that keep at it and get their General (or any of the others). After all, what does amateur radio really have to offer a newcomer? Many of the statements that might have once been true about amateur radio don't seem to even apply to amateur radio now.

Jim Pruitt WA7DUY/AFB7DUY
111 Hirschbeck Heights
Aberdeen WA 98520

New FM'er

Dear Wayne,

I have decided to become a ham and I am studying for a Technician license. I plan to go on 2 meters FM, but I am having trouble locating an FM unit. I hope they are not expensive! I am not in an ideal antenna location and might have trouble mounting a large array. I hope I can get good distance with a less expensive antenna. I have heard of hand-operated rotors from the old days and if I could find such a system, it would be practical since my shack would be in the attic.

I hope there is enough activity on VHF FM so that I can get some good QSOs. I started interest in FM when I heard so many 80 meter AM hams talk about such 2 meter nets.

My main interest would probably be ragchewing and possibly DX (especially when the aurora kicks up, as it sometimes visibly does up here). I have most of the technical part of the exam wrapped up and the code speed is coming, slow but sure.

Rae Shortt

Lots of FM gear available. Check the Double Bonus subject index in the back of this 73.

More Backlash

Dear Wayne:

Your recent thorough treatment of the incentive licensing problem, relating it to the miscalculations emanating from Newington, were excellent. Keep up the good work.

I detect a groundswell of considerable magnitude on this matter, with everybody giving up on ARRL as the source to look to. In this state hams are writing directly to the FCC to lodge their protests.

I suspect that Newington will change its mind eventually . . .as soon as ARRL revenue drops off and salaries must be cut.

Still More Backlash

Dear Wayne:

It is not often I write letters, but after reading so many comments in your magazine and also in another magazine I thought I would also comment.

I did not think the ARRL's incentive license plan would be worth very much and it seems I was right. I don't know what the extra education necessary to get the Extra Class license is going to do for the greater number who get it. If they are going to follow a commercial radio future, it might be of value; otherwise, I think at least 99% go out and buy a shack full of equipment as soon as the license comes. The ARRL representatives at the Dayton Hamvention admitted the reason there was not too many homebrew projects in QST any more is there are no homebrewers any more.

Why should there be so many classes of licenses? I think after a Novice license any citizen with a capability of 5 or 6 wpm of CW and the knowledge necessary to operate properly should be able to get a license to operate anywhere on any band available to hams. When you go for a driver's license it would be the same to have the instructor tell you that with your limited mechanical knowledge, you could not drive a Cadillac; only a VW until you could upgrade your knowledge. The temporary permit to drive is the same as a Novice–and after you prove you can obey the driving laws, you get your license to drive on any highway in any auto you choose to buy. Why should not any ham, having obtained a regular "license," be able to go into a store and purchase any piece of "ham" gear, then take it home and put it on the air?

The sooner something is done to allow every citizen the rights he is entitled to in this country, the sooner we shall have peace.

Manitoba Centennial Award

Dear Sir,

A copy of the starting date, rules, etc. for our 1870-1970 Manitoba Centennial Award is enclosed. We would appreciate it very much if you would publish this:

The Amateur Radio League of Manitoba will present certificate awards to amateurs submitting proof of the requisite contacts with amateur radio stations in Manitoba. All contacts must be made after Dec. 31, 1969. Contestants must accumulate 100 points. W/K, XE, and VE stations receive two points per contact; all other stations receive five points per contact. (A contact consists of exchanging signal reports.) Contacts may be made on different modes on each band, but cross-mode contacts are not allowed.

Two different members of the Amateur Radio League of Manitoba will be designated "Bonus Hams" each month. Contacts with these stations will be worth double points.

Contestants should send a copy of their log and two IRCs to:

Mr. J. N. Knowles VE4JK
PO Box 365
Carman, Manitoba, Canada

Reciprocal Trade

Dear Mr. Wayne:

I am an Indian radio amateur with call VU2JEZ and a 3 yr subscriber to 73. I am a high school student and India's youngest radio amateur.

Well, it was a sort of impossible urge that made me write this letter to you, hoping that you will understand and sympathize with my problem:

In India out of the 500-odd amateurs, all depend on war surplus and homebrew equipment. The maximum amount an Indian ham spends on a rig is $50 - $75.

I have built my transmitter myself, and I tried to get a BC 348 working (which I had bought on the junk market). But all efforts failed. Well, now I have saved about $100 after two years. I got my ticket 6 months ago, and I'm still not on the air. What I want to propose is this: You ask some other amateur to send me a ham receiver (used will do) and I shall send him Indian goods (antique carvings, paintings, embroidered shawls, etc.). I make this proposal because import restrictions do not allow cash payment.

Thus, he can send me this receiver as a gift and I can send what he wants as a gift!

Or, if he prefers, I can give the money in Indian currency to any of his relatives in India or the USIS in Bombay.

I know I have said what I have to say rather clumsily but, I sincerely hope that you understand my situation and will help me out by dropping a hint to some of your vast multitude of U.S. amateurs.

I shall certainly remember you all my life long for having helped me to get started in amateur radio.

Gopal Kamat (VU2JEZ

Two Cents' Worth

Dear Wayne,

A couple of comments and opinions on articles in the December issue:

1. Topographic maps now cost 50¢ each. Inflation has hit the U.S. Geological Survey too. The Bureau of Land Management has some attractive maps of many areas of the West; available free (the price is right) from BLM offices located in state capitals. These have almost as much detail as the topographic maps.
2. The Swan TV2's instruction book contains a drawing of proper connections for a switch to avoid cable changing from the TV2 and its exciter. It even gives the Swan part number. I got one of these, plus two cables with the Jones plug already attached from them and threw together the switch–without resorting to coaxial relays (no pain, no strain). Only problem was changing one wire on the plug for the low voltage dc for the PC board. The unit would FM on 2m SSB; however, a new zener diode and more suitable crystal (factory-installed at no charge) took care of it. I even power a little 2m preamp from this line.

Boos and Hisses

Dear Wayne:

I take umbrage to W4NVK's article in the December 73. I have yet to align or service any piece of ham equipment that I could not get at least 50 dB suppression of the carrier. Second, there is no way, under any circumstance, that bias shift on finals can cause an increase of carrier content on the signal. For the edification of Mr. Dusina, the author, I service and repair amateur goodies in the Detroit area. My operating bench is loaded with about $4,000.00 worth of equipment. I paid for these items by repairing equipment for 11 meter operators with General class or higher licenses. Only last Sunday, a fellow brought his transmitter over because he could get only 40 dB of suppression and while I checked, he yakked about how many years he was operating and no sense doing this or that to his rig, etc. While he talked, I removed 22 more dB of carrier from his set and $35.00 from his wallet. Anyway, if Mr. Dusina will ship prepaid his bucket of bolts to me, I'll remove his residual carrier free of charge. Otherwise, let him properly center the audio in the bandpass (then a $2.00 mike won't sound so good) and put an rf probe on the antenna output jack–lo and behold, he will have 60 dB of suppression. Next, his remark that a 100W CW signal is 200W SSB is erroneous. *A transmitter cannot put out more power than it has been loaded for without doubling plate voltage.* If you don't believe that, load your transmitter fully on CW, and with a scope, note the height of the solid rf display. Switch to SSB and the peaks will not exceed the CW.

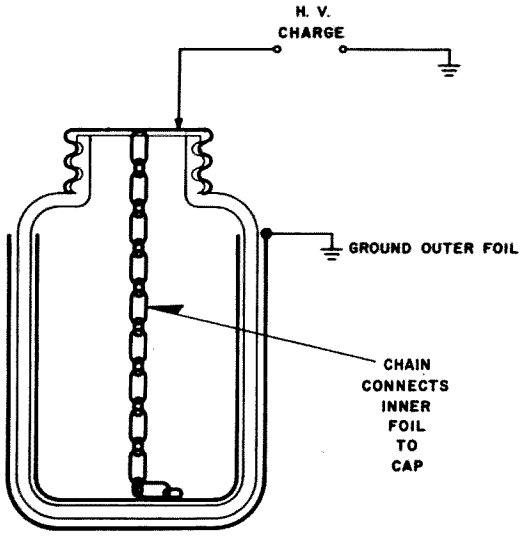
Part IV-The Terrible Jar At Leyden

The year was 1745, and scientific circles were all agog over that strange force called electricity. In England, several decades earlier, Francis Hawksbee had built an electric machine which produced unprecedented quantities of this mysterious power, and Stephen Gray had demonstrated that the power could actually flow from one substance to another. Two Frenchmen, Francois de Cisternay Dufay and Abbé Nollet had discovered two different kinds of electrical power, each capable of neutralizing the other.

Many theories had been offered as to the nature of electricity. The most popular was that it was some kind of an invisible fluid. (That's why we refer to it today as "juice.") All in all it certainly was an exciting time.

Leyden is a small town in Holland, about fifteen miles north of Rotterdam. It was there, during these exciting times, that a distinguished scientist, van Musschenbroek set out to find a way to collect this electric fluid. Could it possibly be collected in a bottle? With the aid of a pupil named Cuneus, van Musschenbroek connected his Hawksbee electric generator through an iron chain to a gun barrel. Another chain hung from the other end of the gun barrel. Van Musschenbroek had his student hold a jar so that the loose chain dangled into it. After the machine had run for a while, the jar was found to have an electric charge, but there was no fluid present. Van Musschenbroek then decided to put some water into the jar. He knew that electric fluid seemed to flow most easily through wet materials.



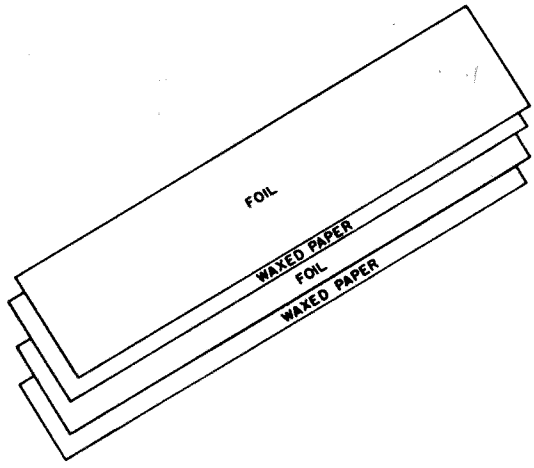
Soon they were set up and the machine was running again. Cuneus held the bottle at one end while the professor turned the generator. This time they carefully watched the level of the water, hoping to see evidence of more fluid. Time passed, and the liquid level in the jar was unchanged. The experimenters were discouraged. Van Musschenbroek stopped the machine, and Cuneus reached up to disconnect the chain.

Suddenly Cuneus dropped the jar and seemed almost to fly backward. The professor rushed over to his student. Cuneus was pale and scarcely breathing. He had received a shock such as no man had ever felt before. After his student recovered, Musschenbroek wrote of his "terrible" experiment to a colleague at the French Academy. He advised that no one else try it. Naturally, everyone else did.

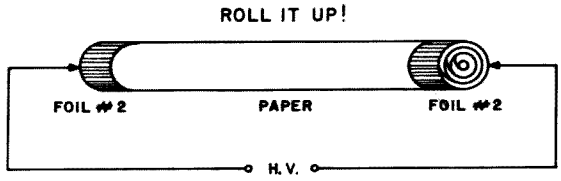
At the same time as van Musschenbroek performed this nearly fatal experiment, the Bishop of Pomerania, E. G. von Kleist did essentially the same thing with similar results. He failed to publish his findings through acceptable channels, that is, by writing of them to a university or other seat of learning, so the credit went to Musschenbroek. The device was named the "Leyden Jar."

The scientists didn't realize it at the time,

but they had actually made a capacitor. The water served as one conductor and the student's hand as the other. The glass was the dielectric. It was later to be improved by using foil conductors, but in the meantime the water was thought to be essential. The scientists believed that the cool water condensed the electric fluid, and the Leyden Jar was nicknamed a "condenser." That term is still used to this day.



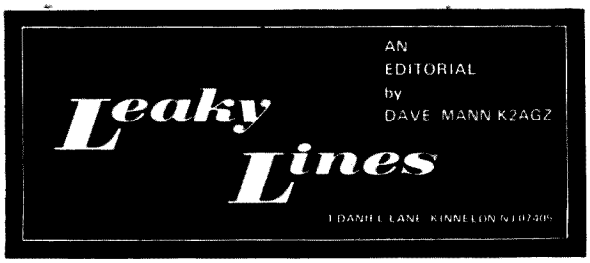
The home experimenter can make his own Leyden Jar quite easily. All that is needed is a peanut-butter jar, some aluminum foil, and a small length of chain. The inside and outside of the jar are lined with foil up to within ½-inch of the top. The chain is soldered to the center of the cover, and hangs down into the jar. It should be long enough that a couple of inches rests on the foil on the bottom.



To charge your Leyden Jar, the outside foil should be grounded. You can use a battery, high voltage supply, or you can charge it up by static electricity. Simply rub a glass rod with a piece of silk and touch the rod to the cover of the jar. If you do this enough times, the jar will accumulate quite a charge.

Now, since some clod might be stupid enough to try it, *don't* connect it to a lightning rod. The early scientists who tried that seldom lived long enough to publish their results.

I once made a capacitor to demonstrate the principle to a group of Boy Scouts, using a roll of waxed paper and a roll or two of aluminum foil. Begin by unrolling four or five yards of waxed paper onto the floor. Place a strip of aluminum foil on top of this so that the foil overlaps the paper by a few



inches on one side, and the paper sticks out an inch or so on the other side. Lay a strip of waxed paper on top of this, exactly covering the first. You now should have a sandwich with the foil in the middle, one edge sticking out. Lay another strip of foil over this whole thing, but protruding on the other edge. The ends of the waxed paper should stick out far enough that the pieces of foil do not touch. Roll the whole mess up

as tight as you can. If you do it right, you'll have a fairly good capacitor. It should take a charge up to 100 volts or so. Mine broke down at 150.

. . . W2FEZ ■

Ever since that time a few months ago, when I wrote, "the handle here is Ignatz. . .Idiot, Garbage, Nuts, Alimony, Termite, Zilch. . ." I have been swamped with unsolicited examples of this outrageous phonetic claptrap. It seems that everyone has a favorite set of phonetics which he wishes to bequeath to a breathlessly waiting world. . .you know the type of stuff. . ."Floyd; Funny Little Old Yellow Dog." And. . ."WA2IWS; We Are Two Indians With Scurvy," and all that sort of penny-dreadful nonsense. The more farfetched it is, the more unfunny it becomes.

Now, as a chap who makes his living by putting words together, I warrant that if I desired to be a party to these grotesqueries, I could doubtless be very successful at it. But I think the thing is starting to get out of hand. We ought, really, to start clamping down on it. Unless it is a brilliant work of sparkling genius, I regard it as just sounding brass and a tinkling cymbal; and besides, it's beginning to fray my nerves.

Can you envision the result if this preposterous tripe is allowed to continue flourishing? Webster's Third New International includes over 450,000 entries, each of which is fair grist for the phonetic fetishist's mill. The possibilities are menacingly infinite! And, bear in mind, please, that's only one side of the problem; our own English language. How about all the others? There's Afro-Asiatic, Altaic, Indo-European, Macro-Khoisan, Malayo Polynesian, Indic, Luorawetlan, Niger-Congo, Sino-Tibetan, Uralic, Azteco-Tanoan, Hokan-Siouan, Macro-Chibchan and Penutian. . . . .a series of main linguistic stocks, covering some 700 different tongues, not counting regional dialects. Add to this the languages totally unrelated to any others; Basque, Andamanese, Ligurian, Yenisei-Ostyak. . .each of the 96 Australian aboriginal tongues, and all 132 of the Papuan languages, and perhaps you'll get an inkling of the utter incongruity and hopelessness of it all.

A long time ago I decided that the use of funny phonetics is not so much a method by which to clarify spellings as it is a display of other things altogether; would-be cleverness. . .sarcasm. . .and most of all, ego! The wildest flights into this adventurism and exhibitionism arise out of a profoundly felt need to assert the ego. Scratch the surface of the guy who gives his call as Willie Broke Four Plate Glass Windows, and underneath you are likely to discover an insecure, uncertain, indecisive, vacillating jerk with a pronounced inferiority complex, who is attempting to bolster his inward weaknesses by earning a reputation for great wit and brilliance.

Now please, I beg you. . .no more phonetics in the mail. I just can't take any more. However, if you're interested in some real clever ones, I just happen to have a few dillies. Just five bucks apiece; two for eight ninety-five; first come, first served. But, please keep it under your hat. I wouldn't want anyone to get the mistaken idea that my ego needs bolstering. Not a bit of it!

* * *

There is a situation which has arisen, and I'd like to throw it out to see what you all think about it.

A friend of mine who was a member of ARRL for many years, but who dropped his membership just before acquiring his Extra Class ticket, was in contact with another chap in the same boat. Both these boys are members of the highly vaunted A-1 Operators Club, and both are well seasoned, having a combined total of over 65 years of hamming under their belts. They are not given to shoddy operating habits, nor have I ever found them to be anything but considerate and courteous. From any point of view they are decent people.

Because they are not members of the League, they seldom read QST, and they were unaware that W1AW had changed its operating frequencies. This, despite opinions to the contrary, is neither here nor there. Even the membership of the League is not wholly aware that the frequencies have been changed.

Well, anyway, these two guys were in contact one evening on about 38.20. In the midst of a transmission, and without the slightest advance warning, in came the Official Bulletin from Newington. It wiped out the QSO as effectively as if the band had gone dead.

Improve your CW sending!

NEW AMECO CW MONITOR & CODE PRACTICE OSCILLATOR

■ Monitors Transmitter's CW ■ Transistorized
■ Kit or Wired ■ Built-in Speaker ■ Low Cost

The Model OCM is a combination Code Practice Oscillator and CW Monitor. It monitors your CW sending with a simple (no modification) connection to the keying terminals transmitter. It may be used with any transmitter or transceiver employing negative bias keying. A tone control, as well as volume control, and head phone jack are included on the front panel. Built-in back-to-back diode switching makes it unnecessary to turn the unit on and off, even when switching from CW to Phone. Current drain only takes place when the key is actually depressed. The model OCM contains one transistor and two diodes. Size: 6" x 3" x 2"

Model OCMW (Wired & Tested) (less batteries)
Model OCMK (Kit form) (less batteries)

AMECO *Leader in Compact, Quality Ham Gear*

P.O. BOX 6527, RALEIGH, NORTH CAROLINA 27608

A Division of Aerotron, Inc.

Now, if WIAW is an amateur station, operating within the same restrictions as the rest of us, then why may they be excused when they commit a breach of courtesy toward other stations. We are all expected to observe the etiquette which the ARRL prescribes: to check the frequency before transmitting. Even if a net with a scheduled operating time discovers that its frequency is occupied, the SCM has the decency to request that the occupant QSY so that the net may operate on a clear channel. If the chap who is thus asked is a gentleman, and most of them are, he will most assuredly move. But, to come right on the frequency without even checking to see, seems to me to be the most arrogant and unwarranted type of rule-flouting in the book.

Since WIAW happens to be the League amateur station, I feel strongly that it should be operated in an exemplary fashion. There is no valid excuse for breaking this basic regulation. In fact, if some extenuating circumstance were to excuse an individual ham for doing this, WIAW should be operated so superlatively that the case would never have arisen. No station should break this rule. It is most distressing when the rule is circumvented by the Headquarters station.

When the bulletin was over, the operator signed the call and announced that the station was standing by for calls. My friend gave them a call and they came right back to him. He took issue with the operator, asking him why he had not checked the frequency before transmitting the text of the bulletin. The operator replied, "I can't comment about that. If you wish to complain, you may write to the League, and take it up with them."

Well, that's it. What do you feel about it? Do you think that WIAW, despite its undeniable help to amateurs, should have the right to ignore the good operating practices which we are all constantly enjoined to observe? I do not think so. But that's only my opinion. What's yours?

* * *

This isn't an original idea, of course. . . .I'm sure somebody must have proposed it. Why, if there's a thing called Operator of the Month, isn't it feasible to publish a list called Lid of the Month? Some of the characters on the ham bands really do deserve this sort of publicity, as you will undoubtedly agree. It's just too bad that the most iniquitous ones invariably operate anonymously, so that it's difficult to identify them.

One thing is certain. If you would like to discourage the intrusions of unwelcome carrier throwers, burpers, whistlers, razzers, and other intruders, never. . . .but never, never comment openly about them. That's exactly what they want in the first place. So don't give them the satisfaction of successfully provoking you into an altercation on the air. If you ignore them, chances are that they will move off your frequency and seek someone else who might just rise to the bait.

Apropos of my recent rhymed diatribe against TV commercials, I recall with delicious amusement an incident of about six years ago.

My father, who had a marvelous admixture of bored cynicism and a highly sophisticated sense of humor, loathed and abominated TV commercials. One of these in particular used to offend him very much. There was an animated character with a head formed of a seltzer tablet. He sang a childish little jingle which ended with an advertising slogan for the product. You simply could not avoid this thing . . .it was like the plague; repetitious and redundant.

Dad got hold of an old mezzo-tint of Socrates, drinking the cup of hemlock. In bold letters, and with a red marking pen, he inscribed it, and sent it to the advertising agency which handled the account. His inscription read, simply, "RELIEF IS JUST A SWALLOW AWAY."

* * *

I'd like to discuss an event which rankles in the breast of almost every amateur even now, several years afterward. I refer, of course, to the removal of 27 MHz from the amateur spectrum, and its reassignment and deterioration into the monstrosity and misbegotten mishmash it was inevitably to become.

Most of us have to take a position. We cannot blow hot and cold with the same breath. We cannot plant both feet firmly in mid-air. Yet, there are those who pretend to be the champions of both contending forces, both unalterably in opposition to each other. . . .both of whose interests lie clearly in diametrically opposite directions.

Can you imagine a man playing both sides of a chessboard? Can you conceive of one general acting as strategist for two warring armies? Can you picture one attorney representing both plaintiff and defendant in a lawsuit? And, if such a lawyer were to advise you to act in such and such a manner, would you be expected to follow his advocacy with implicit faith and confidence? I think not. You would be most imprudent, if you did.

A certain publishing company issues two magazines; one for hams; the other for CB'ers. Now this, in and of itself, is certainly no sin. It is perfectly possible to serve the interests of both, SO LONG AS THEY DO NOT ATTEMPT TO GAIN AN ADVANTAGE FOR ONE, AT THE EXPENSE OF THE OTHER. Through the years, however, in the pages of CQ Magazine, we have seen hints, outlines, draughts, suggestions, proposals, resolutions, and motions, all calling for the creation of additional frequencies for Citizens' Band. They have called for the implementation of a new class of amateur license which would open up the ham ranks to CB'ers, (as if the doors were closed to them now). There is a persistent subterfuge—a nice little fiction—that these people constitute a pool of potential amateur operators, the encouragement of whom all will ultimately supplement our growth, and make us strong and healthy. In other words. . . "Let's have this teentsy-weentsy slice of 10 meters, fellows. You're not using it anyway. Let's allow these nice, deserving folks to use it so that they can develop their skill and talent. They are really different than you think, way down deep inside. They are serious, earnest, purposeful and dedicated, and we owe them an opportunity to develop these splendid and sterling qualities so that they may take their rightful place beside us as full-fledged amateurs.

Now, really, I ask in all candor. . .is there a single ham who has the slightest inclination to take this stuff seriously? I certainly hope not! The only quarter in which it might meet with approval is among the CB manufacturers.

Picture this fantasy. The moment these fine, misunderstood fellows are given these additional frequencies, they will instantly begin to observe all the FCC regulations. By some strange and miraculous atavism, they will become first-class operators. The only thing, you see, that keeps them from doing this right this very minute, is because the poor dears are all squeezed and squished into those horrid, little 23 channels. That's why they call skip, use VFOs, run high power, use illegal antennas, don't give proper callsigns, interfere intentionally, persist in the use of profanity and obscenity, and break all the other rules. But never you mind; the moment they are granted this allocation, they will change. They will become fine, law-abiding members of the ham fraternity, and dedicate themselves to constructive purposes. They will be a credit to us all. Just do away with the nasty old code and theory requirements. . . please . . .pretty please . . .and you'll be surprised at how they'll change.

I'm not anxious to pillory CQ. I have some very good friends there—people for whom I have the utmost regard. But I can't help feeling that the front office allowed its "druthers" to be seen in public print, in spite of—not because of—these nice people. And I think that we hams ought to express our united opposition to all such plans, though they may sound ever so lofty and constructive. They can have but one result. . .the weakening of amateur radio. And there has never been a time in our history when we needed so badly to maintain all the strength we can muster.

* * *

A few weeks ago it was decided that I would lie "doggo" on the subject of the League for a while. Wayne felt, and I agreed with him, that there would be no point in continuing to take issue with certain aspects, since I had already expressed most of the reasons for my objections, and had given voice to many of the sentiments unexpressed by the common, garden-type variety of ham, which deserved to be articulated. I fully intended to concern myself with other matters which would be of interest to the readership. But I find that I cannot seem to get away from these issues, after all. The latest issue of QST includes a League proposal, which, if advanced to FCC as it is now proposed, can possibly be even more dangerous than any other ARRL-sponsored change within memory, including incentive licensing.

At this point, allow me to emphasize unequivocally that I have absolutely no prejudice against those who hold Technician grade licenses. If I do object to any of them, it is on the ground that *some* of them operate in violation of the spirit, if not the letter of the FCC regulations. Many of them, probably a majority, conduct themselves conscientiously, but it is simply impossible to ignore the infantile antics of the violators among them. This is not to say that there are no culprits among other classes of amateurs. But the reasons are not the same. In my judgment, one of the important reasons for the misbehavior of certain individuals among Techs, is that they obtained their licenses fraudulently to begin with. Many well-meaning operators, acting in the prescribed role of volunteer examiners, and probably in a spirit of overpermissiveness, have given an inordinate measure of assistance to applicants for the Tech ticket. In some cases the CW requirements were completely bypassed. In other cases the examiner rendered illegal aid on the written portions of the examinations. In this fashion a group of persons who were never really interested in conforming to the stated purpose of this particular grade of license, but who were merely desirous of pursuing the communications end of the hobby, were permitted to infiltrate the ranks of the Technicians. They became figuratively and literally marooned in that category, because there were but few avenues through which they might upgrade their skills in order to meet the standard requirements for the other grades. There have been Techs, of course, who buckled down to work, and developed their code speed. But, on the whole, they did not seem to care too much about becoming General class operators, being content, rather, with staying in their own special niche.

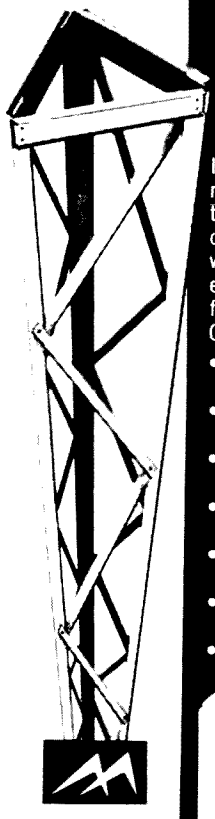
There is no point beating about the bush. You have heard, as I have, the expression "mail-order license" used over and over again. There is no doubt that a sizable segment of those who hold this ticket earned it as a result of less than fastidious observance of the rules by the volunteer examiners. And this practice, though it might appear to be negligible in actual numbers, has tended to lower standards for entire group.

Now ARRL has decided to propose that Techs be permitted phone and other privileges between 29.5 and 29.7 MHz. There is no mention of any qualifying examination for this additional privilege. And I believe that each and every ham who had to go and upgrade his ticket in order to continue to operate, not on newly granted frequencies, but on the same frequencies where he had previously been entitled to do so, should be raising his or her voice in protest. It may be perfectly true that this particular slice of the spectrum is not overused. It may be lying completely fallow. But this fact should not constitute justification for cheapening or vulgarizing it in this fashion.

I say, compel all Technicians who wish to avail themselves of this or any additional privilege to submit to a proper examination in the presence of an official FCC examiner. Those Techs who wish to get this additional slice of the spectrum should be, and undoubtedly will be, in my view, willing to buckle

down, as did the rest of us in similar circumstances. This privilege, if offered at all, should not be a free gift, but an incentive. If the League truly believes that incentives will really upgrade the quality of amateur operations, then it *must not* allow this concept to be torpedoed with an inconsistent approach toward one segment of the ham population! If the League is thinking that it will gain membership as a result of a huge and enthusiastic influx of grateful Techs, responding to this magnanimous gesture on the part of Newington, let them contemplate the wholesale hegira from the ranks by thousands of members, already disenchanged with the way things have been going. For every grateful Tech who joins ARRL, I believe there will be a score of members of long standing who will simply quit in disgust.

I am very unhappy with this proposal. I would be much more unhappy if I thought that my fellow amateurs would allow this proposal to go through without a mighty outcry of dissent. If we do not yammer to our directors and to the League executives about this injustice, we will not have the right to complain about it afterward! Nor would we deserve that right.



Here is a golden opportunity for us to test the League's willingness to be responsive to the desires and needs of its members. Typically, of course, in its time-hallowed attitude of paternalism, the League will tell us that it knows what is best for us. Is there anyone left who actually believes this? Is there any soul who has observed the debacle of the unused sub-bands, and the horrendous congestion in the unrestricted portions, who can be gullible enough to buy this ancient and worn-out canard?

I would be very much surprised if this atrocious proposal should meet with the approval of the majority of the amateurs. Since it would result in an advantage to some, gained through preferential bias for this one license grade, it spells a disadvantage, in effect, for all the rest of us.

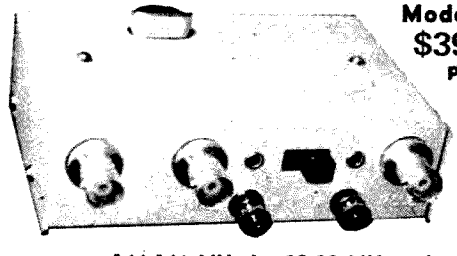
Let us all make certain that we express our feelings on the question. Let no amateur fail to communicate with ARRL and its leaders, so that we may avoid a perilous situation in future years. This proposal constitutes a dangerous precedent. It would enable some FCC, as yet unnamed, perhaps, to reassign portions of our bands to whomever it wishes, on the simple ground that it is right to exact standards of ability from some, while permitting others to ignore any standards whatsoever! It would also establish that frequencies which are not widely utilized may be preempted by groups which might make more use of them. On this basis it would be possible to witness a gradual attrition of the entire amateur spectrum, through their reassignment to anyone or any group with sufficient influence to convince or mislead the Commission.

Please, I entreat you with all earnestness and sincerity, do not let this proposal get to first base. This could be the most important decision you can make during your entire amateur life. Don't let it get through, especially by default. Write, wire, and call your director. Do it today!!!!

. . . Dave Mann K2AGZ■

AL SERIES ALUMINUM TOWERS for uhf - vhf

Ideal for mounting industrial, commercial, citizens band, amateur, or television receiving antennas. Exceptional strength in proportion to weight qualities. Easy access to equipment mounted on the Microflect top mast extension.
Other features are:



- 10 to 120 feet high in easy to erect 10 foot sections.
- Available factory assembled or in kit form.
- Lightweight all aluminum 10 foot sections weigh only 12½ lbs.
- Low maintenance, will never rust or require painting.
- Staggered ladder treads for easy climbing.
- Can be used for direct radiator at HF.
- Wide variety of mounting brackets and accessories available

THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.

144-146 MHz in. 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.

Emergency Net Changes Name, Frequency

MEDINET—Medical Information Network—is the new name of the Public Health Service Emergency Radio Network, the Secretary of Health, Education, and Welfare announced today. The network was organized a year ago by the Division of Emergency Health Services, Health Services and Mental Health Administration, to provide communication during health emergencies when downed telephone lines have closed normal communication channels.

MEDINET is made up of employees of the Department of Health, Education, and Welfare (HEW) who live outside the Washington, D.C. metropolitan area and who are licensed amateur radio operators, or "hams." MEDINET's most vital function is to provide rapid communication among health officials at the local, state and federal levels during disasters. When normal communications channels are closed, MEDINET steps in to insure the fastest possible response to the health needs of disaster areas. Participation in MEDINET is voluntary. It is undertaken as a public service by the HEW employees involved. When an emergency occurs, MEDINET members are excused from their normal duties so that they can participate in the network. Network control for MEDINET is provided by the National Institutes of Health Radio Amateur Club station, K3YGG, at Bethesda, Maryland, a Washington, D.C. suburb.

The change of name, from PHS Emergency Radio Network to MEDINET, will permit routine on-the-air meetings of the network's members without any Federal connotation. To promote the use of a single frequency by all medically oriented networks—such as the Medical Amateur Radio Council, Ltd., an organization of physician hams—MEDINET's frequencies were recently changed to 7260 kHz and 14280 kHz (with 21360 kHz as an alternate).

Presently, MEDINET is meeting on the air every Monday at 12:00 noon and every Wednesday at 5:00 p.m. Eastern Time. MEDINET Control, K3YGG, operates at 20 meters on 14280 kHz and 40 meters on 7260 kHz simultaneously at these times.

A few of the MEDINET members do not have transmitters powerful enough to communicate directly with Washington, D.C. MEDINET, however, is set up so that it can relay messages from station to station across the continent. This technique was used with dramatic success in the recent Hurricane Camille disaster on the Gulf coast.

Announcement

12th Annual Dinner

The East Coast VHF Society's 12th annual dinner will be held Saturday, March 21, 1970, at the Neptune Inn, Route 4, Paramus, N.J., starting at 7 p.m. Ted Mathewson W4FJ will talk on "VHF—Past, Present, and Future." Awards will be given by Ed Tilton W1HDQ, including awards for highest single and multioperator station in the September VHF contest. The menu will be prime ribs of beef and tickets will be sold for $7.50. Group reservations are available in blocks of 5 to 10. Ticket deadline is Wednesday, March 11. For tickets and reservations write the East Coast VHF Society (WA2WEB), PO Box 1263, Paterson NJ 07509.

Amateur Radio

AMATEUR RADIO IN INDIA

Marie Welsh W6JEP
Reprinted from LERC Bulletin

G. V. Sulu (VU2GV) was kind enough to send a copy of the Radio & Electronics Society of India (RESI) Book Series 1 Amateur Radio Regulations in India, compiled by M. V. Kini (VU2SZ). This 1968 First Edition is very interesting and our readers may appreciate the following highlights which I've extracted from the book:

1. No 160 or 6 meter privileges.
2. 10 kHz only on 80 meters; 3890-3900 kHz.
3. 100 kHz only on 40 meters; 7.0-7.1 MHz.
4. 20, 15, and 10 meters are the same as our bands.
5. 2 meter band is 144-146 MHz.
6. 420-450 MHz also used by radio altimeters.
7. 1215-1300 MHz shared with fixed and mobile services.
8. 2300-2450 MHz primarily assigned to fixed, mobile, and radio location services. 2450 MHz shared with Industry, Medicine, and Scientific groups.
9. 3300-3500 MHz shared with fixed and mobile services.
10. 5650-5850 MHz shared with fixed and mobile services; 5800 MHz is for industry, medical, and scientific purposes.
11. 10.000-10.500 GHz and 21-22 GHz are used as ham bands.
12. The top license is called Grade I. This ticket is available to those who are 16 or older. The code test is at 12 wpm and the theory test is about the same as our Novice exam.
13. The other license is called Grade II. This ticket is available to those 14 or older. The code test is at 5 wpm and the theory test is 25% easier than the Grade I exam.
14. The maximum input power for SSB operation has been increased from 100 to 400W PEP.
15. Mobile operation is now authorized on the VHF bands.
16. There are about 500 licensed hams in India, and the majority of them are quite new to the hobby.
17. Ham literature is very scarce in India and ordinary electronic components are just about nonexistent.
18. Amateur licensing exams are conducted (by appointment only) at 5 monitoring stations of the Department of Communications and Civil Aviation with requests addressed to the Wireless Adviser, Wireless Planning and Coordination, Ministry of Transport and Communication.
19. The Grade I exam fee is 10 rupees and the Grade II fee is 5 rupees.
20. Grade I station applications cost 15 rupees and Grade II ones cost 10 rupees.
21. Grade I licenses will soon be renewable for 3 years at 42 rupees.
22. Grade II licenses are not renewable after 3 years; the holder must upgrade to Grade I or lose his license.
23. Ham licenses can be granted to nationals of other countries.
24. Station particulars must be detailed on the

News Page

station application. If not commercial or surplus equipment, a diagram of the transmitter must be attached. Receiver details must be attached. A sketch of the antenna (showing dimensions and mechanical supports) must be included.

25. The powers at the (1) power supply, (2) final amplifier input, and antenna input must be stated on the station application.
26. The desired transmitting and receiving frequencies must be stated on the station application.
27. The equipment frequency range capability must be stated on the station application.
28. Two passport-size photographs are required with the operator application.
29. The applicant's physical description and personal data are required on the operator's application.

FCC Notes

CB Traffic Reporting Authorized

CB rules (Section 95.83(a) (14) have been amended to permit licensees to transmit information on highway conditions to persons or emergency organizations furnishing such information to the motoring public by way of radio broadcast facilities (Docket 18625; RM-1388). The amendment will provide for road information furnished by a CB radio station to be compiled and edited by the broadcaster and then announced over a broadcast facility.

40 Meter Segment Opens for Ham Band Marine Operation

Amendment of the amateur service rules Section 97.95(b) (2) concerning maritime mobile operation permits United States amateurs, when outside the jurisdiction of a foreign government, to operate in the 7.0-7.1 MHz band in areas of Europe, Africa, and Northern Asia (Region 1) and Southern Asia and Oceania (Region 3), effective December 31, 1969. The 40 meter frequencies from 7 to 7.1 MHz have been allocated for exclusive use of the amateur radio service on a worldwide basis.

Fort Sill Fest

The annual Fort Sill hamfest will take place in Lawton, Oklahoma on February 22. For details, write Lawton—Fort Sill ARC, Box 892, Lawton OK 73501.

Storm Warning

In the March 1969 issue of Popular Science there was an interesting article explaining the Newton Weller system of using your TV set as a tornado warning device. The mechanics are simple:

- Tune your TV set to channel 13
- Turn the brightness control until the screen is dark
- Tune to channel 2

If the screen is white, then there is a tornado nearby. White streaks on the screen are an indication of lightning activity. A dark screen shows there are no electrical storms in the area. If there is a local station on channel 2, you may see its picture instead of a blank screen.

Newton Weller found that tornados have an oscillating electrical field around the eye. The frequency of this oscillating field is very close to 55 MHz (that is, channel 2). One darkens the screen while tuned to channel 13 to give a reference as far from 55 MHz as possible. The high signal level produced by the tornado or electrical storm is enough to turn the screen white on channel 2.

. . . WA6YZD, as lifted from the Sacramento Club paper

Blossomland Annual Auction

The 3rd Annual Blossomland Amateur Radio Auction will be held March 15, 1970 at the Youth Memorial Building, Berrien County Fairgrounds, one mile north-west of Berrien Springs, Michigan.

Last year over 300 amateurs turned out for Southwestern Michigan's fastest growing ham event, and went home with carloads of fine gear (or money). The 1970 auction promises to be bigger and better.

Acres of free parking will be available for the trailerloads of bargains that will no doubt show up. Don't pack a lunch. . .hot food will be available. Prefer to do your own selling? Rent one of the swap tables. If that fails, a skilled auctioneer will put your gear on the block.

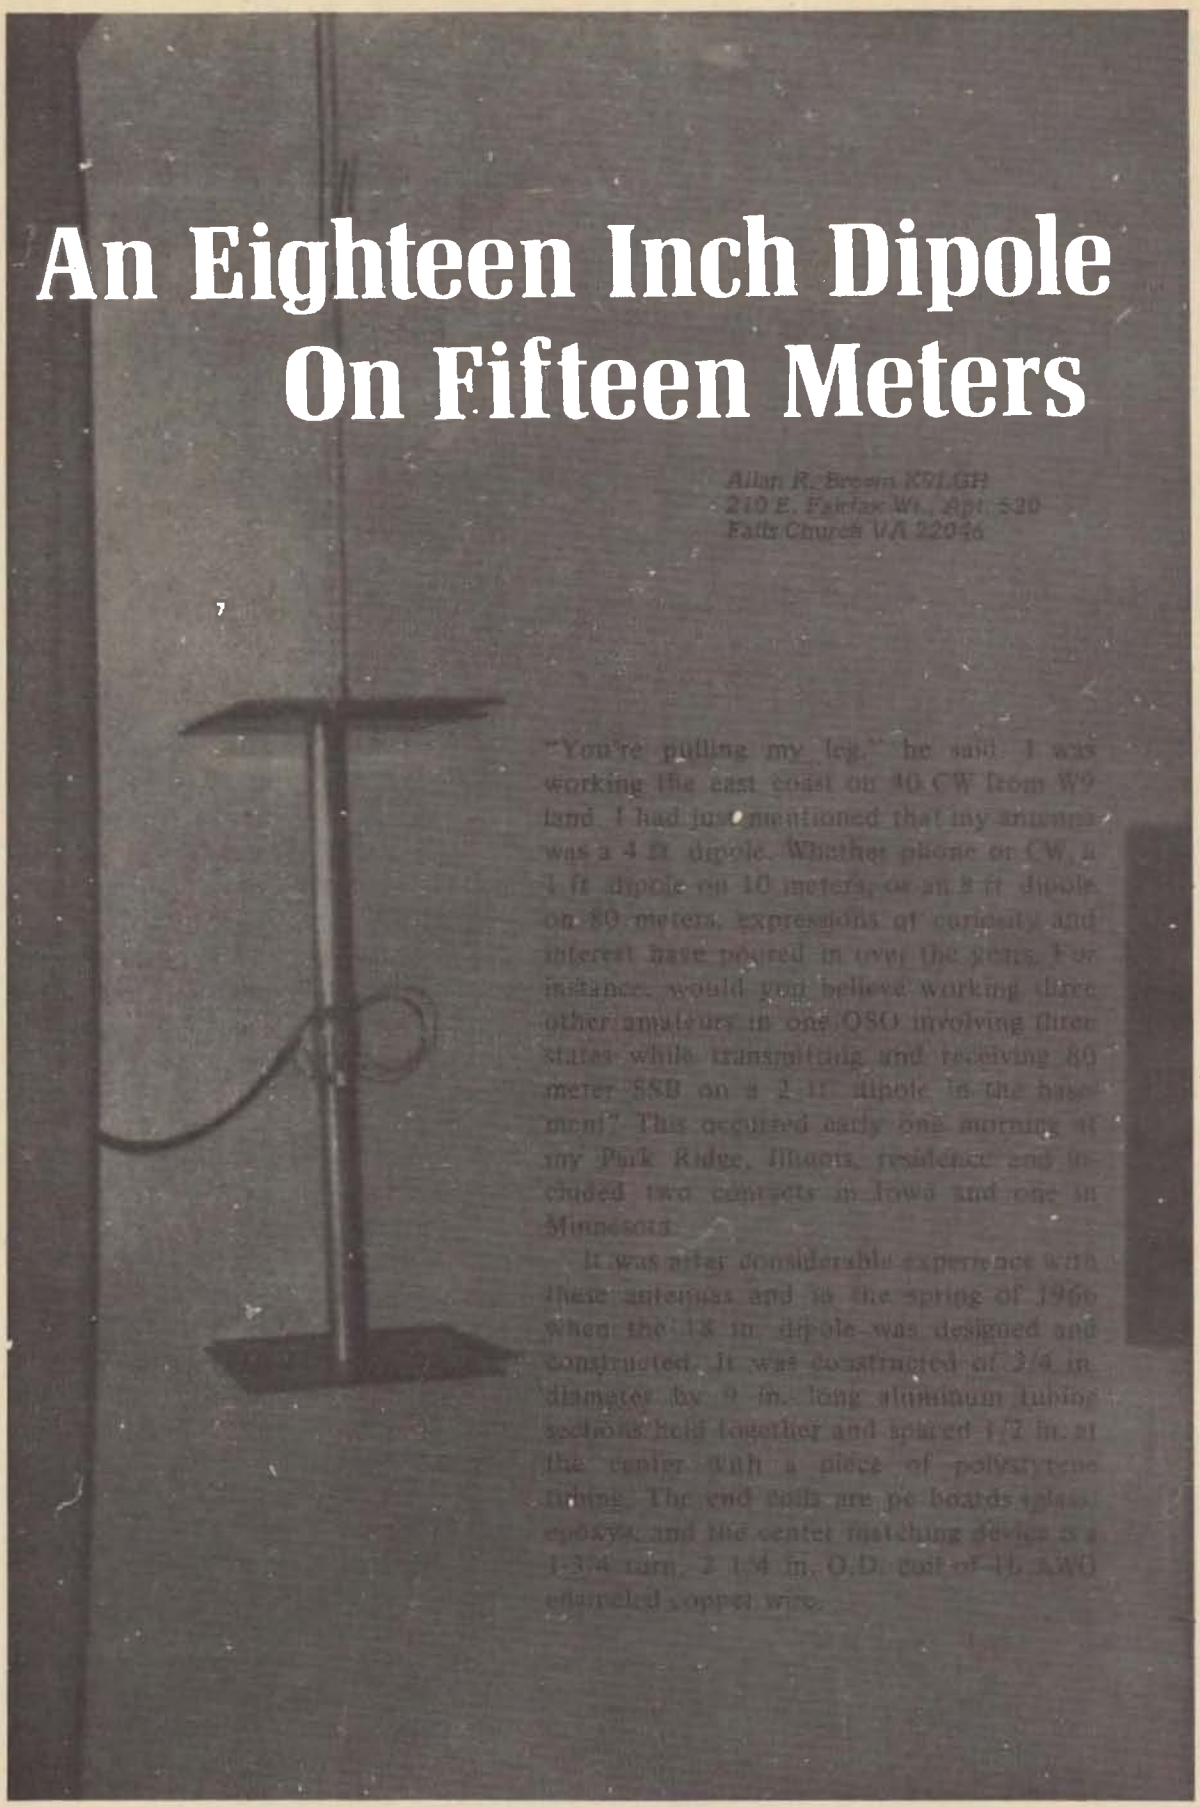
One happy ham went away with a Heathkit Hotwater 100—the grand prize last year. A lot of others won smaller items. What will this year's door prizes be? Be there March 15 and find out.

Coming from out of town? Just get on US 31-33 to the Fairgrounds north of Berrien Springs. Running mobile on 75 or 2? Direction service and call-in on 3925 or 146.94 FM.

Check your shack now. . .and be at the auction between 10 a.m. and 1 p.m. (starting time) to convert that old gear into something easier to carry. . .money.

OLD TIMERS

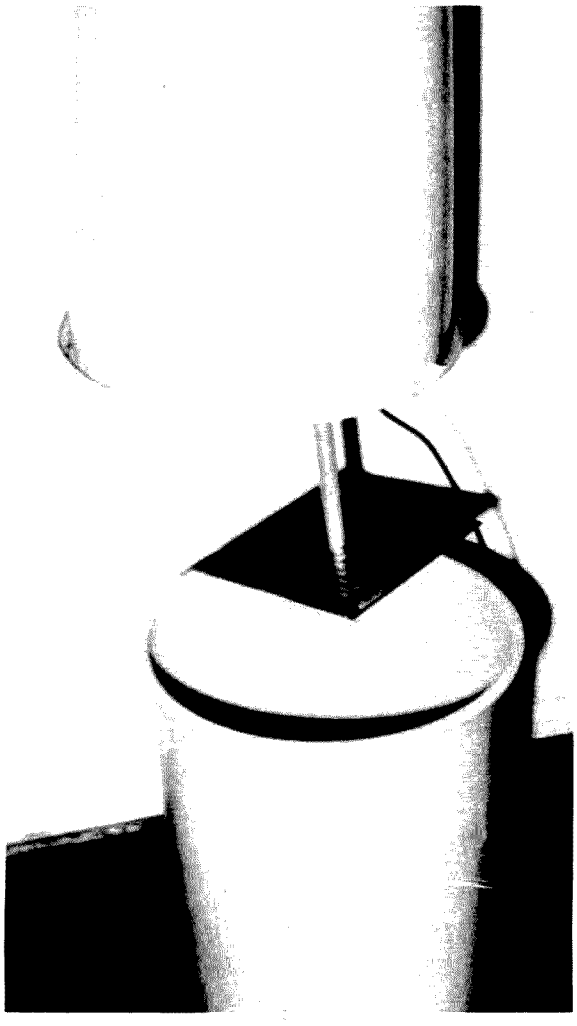
The "Old Timers Dinner" for the Southeast U.S. sponsored by the Birmingham Amateur Radio Club will be held at 7:30 p.m., February 14, at the Holiday Inn East (Highway 78 East). Leland Smith, W4AGI/W5KL, will be the featured speaker.



This appears to be an annual event, predicated on the tremendous crowd attending last year. A license issued before 1930 entitles a ham and his wife to a free dinner.

Antique equipment, magazines and "hams" will be on display.

For further information contact W4GET or W4AXL, Box 603, Birmingham AL.



An Eighteen Inch Dipole On Fifteen Meters

Allan R. Breem K9LGH
210 E. Fairfax Wt., Apt. 520
Falls Church VA 22046

"You're pulling my leg," he said. I was working the east coast on 40 CW from W9 land. I had just mentioned that my antenna was a 4 ft. dipole. Whether phone or CW, a 3 ft dipole on 10 meters, or an 8 ft dipole on 80 meters, expressions of curiosity and interest have poured in over the years. For instance, would you believe working three other amateurs in one QSO involving three states while transmitting and receiving 80 meter SSB on a 2 ft. dipole in the basement? This occurred early one morning at my Park Ridge, Illinois, residence and included two contacts in Iowa and one in Minnesota.

It was after considerable experience with these antennas and in the spring of 1966 when the 18 in. dipole was designed and constructed. It was constructed of 3/4 in. diameter by 9 in. long aluminum tubing sections held together and spaced 1/2 in. at the center with a piece of polystyrene tubing. The end coils are pc boards (glass epoxy) and the center matching device is a 1-3/4 turn, 2 1/4 in. O.D. coil of #16 AWG enameled copper wire.

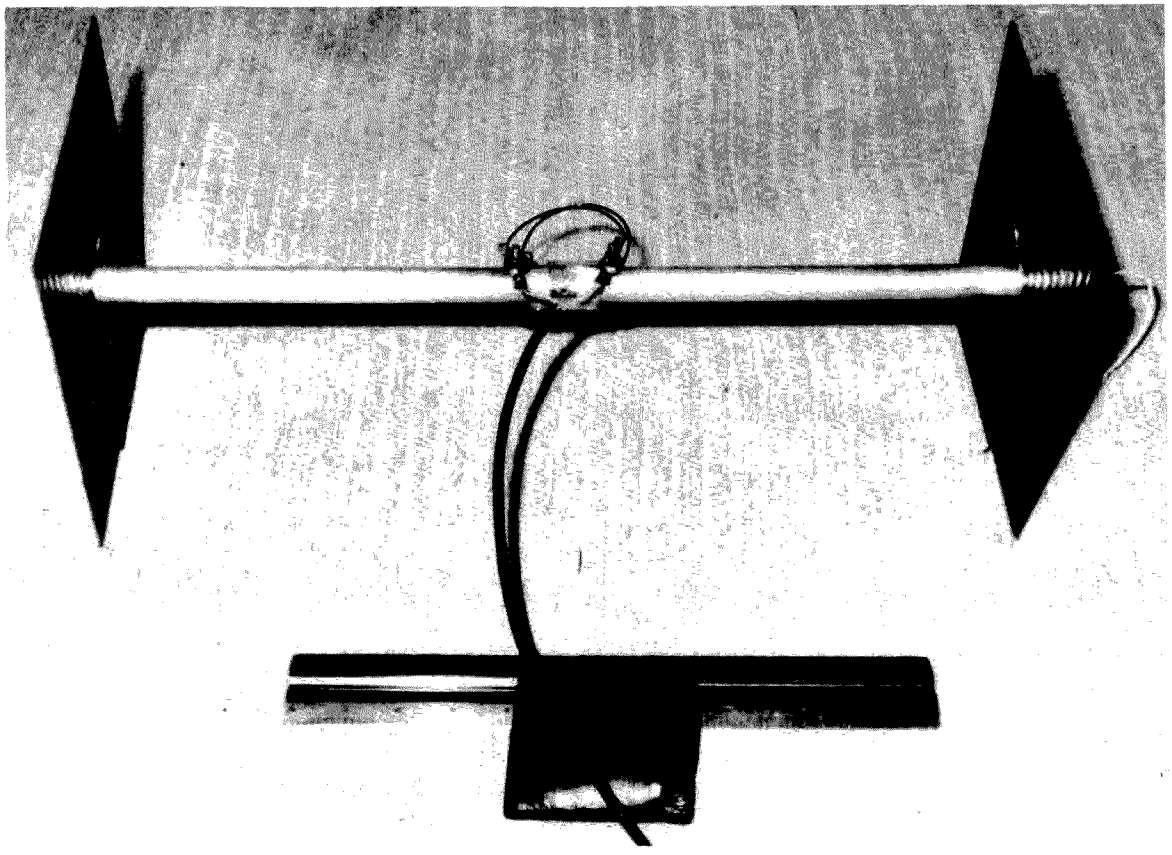
The circuit boards were hand painted with photoresist after first ruling the edges of the lines with a resist pen. Then the circuit boards were etched with ferric chloride. The ends of the straight dipole section were plugged, and the coils held in place with a single screw in each end. There is one left-hand and one right-hand coil, so that with the conducting sides of the coils turned toward each other, the currents in the coils oppose each other to reduce premature radiation.

The final touch is the tuning means, which consists of telescoping brass tubings (I obtained them from a local hobby shop). The inner tubing is 1/16 in. O.D. and the outer tubings are soldered to the ends of their respective coils.

This little antenna turned out to be my favorite, as it was inconspicuous and could be taken down and lost in a small piece of airplane luggage. Since it is matched to a 50 ohm coaxial cable (usually RG-58/U), all that is necessary is to connect it, tune it, and go on the air.

Good results were obtained from the outset with the antenna sitting on the nylon web of a lawn chair on the balcony. In the fall I hung it in two plastic wastebaskets, one inverted on top of the other; there it sat all winter long bringing in the contacts. The maximum power used was provided by four 1625 tubes in a homebrew grounded-grid linear. Estimated input is 300W PEP with additional feedthrough from the exciter. That power level is about the limit for the printed circuit coils.

These antennas have been a real fun thing, from the very first successful model—which was a 2 ft dipole on 40 meters. A prototype 4 ft antenna was made for 40 meters and a few were made and sold to test the market. There is presently no commercial product available, but a patent* has been granted on the antenna.



The antenna system comprises an end-loaded dipole with matching impedance in the center. The straight dipole has a high radiating efficiency, and there is undoubtedly a substantial contribution from the strong electrical dipole produced by the two end coils which are opposed magnetically. This accomplishes two things:

1. Radiation at right angles to the principal field of the straight dipole is reduced or nearly eliminated.

2. Radiation off the ends is also greatly reduced, thus avoiding or reducing losses which might otherwise occur through coupling with nearby lossy objects.

Although a highly efficient antenna should be possible in this configuration, the efforts have been concentrated on making small lightweight antennas, for economy, ease of handling, and with minimum space requirements. The actual efficiencies would be very difficult to calculate since the distribution of the current in the coils is a

*Patent No. 3,432,858 owned by the author. The author does not object to having amateurs build these antennas exclusively for their own experimental use.

The keycase and ruler are shown beside the 18 in. 15 meter dipole for size comparison. A string attached to a clamp under the screw on one end permits hanging the antenna from a convenient support. One word of caution: the coax must be kept several inches away from the coil edges to avoid a detuning effect.

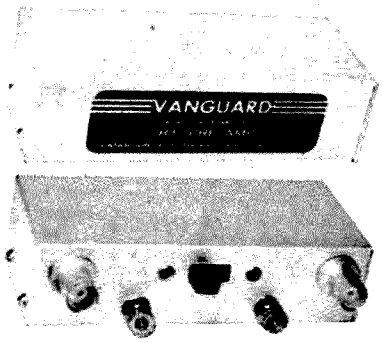
complex phenomenon. However, with antennas, performance is the prime criterion—and this has proved very gratifying; the antennas have been tested and used by several of the author's friends with consistently good results.

One of the greatest advantages of the antenna is its small size and weight which permit it to be placed more favorably at times than such antennas as the ground-based vertical or a half-wave dipole. Taking advantage of its size and independence from the ground, it can be placed at an optimum height for the desired angle of radiation. Or it can be used either horizontally or vertically to achieve optimum propagation over short or long hauls. For example, the 4 ft 40 meter dipole worked very well vertically for the long hauls, but better horizontally for distances of 60 to 100 miles.

The advantage of raising the antenna to an optimum height, which for longer skips may be one-half to one wavelength above the ground, may be seen from the graphs contained in an article by W. H. Anderson VE3AAZ (Antenna Behavior Over Real Earth, QST, June 1965, pages 61-64). The 9 ft 40 meter antenna weighed 3 1/2 pounds and thus could be placed on a light support anywhere on the house or other structure where a little free space was available. Thus in a vertical position at some height above the ground, it might perform as well, or better, than a quarter-wave ground-based vertical. As seen from the above, there is no reason why the antenna cannot be mounted horizontally and rotated. This, of course, has been done, and although the tests made were not extensive, it was found that the short dipole (4 ft on 40 and 8 ft on 80 meters have been tried this way) behaved directionally about like a half-wave dipole.

Very good results have been achieved with the 40 meter dipole in the vertical position at a height of 25 ft. Africa and Ireland were worked from the W9 location with this arrangement. However, one thing

was learned with the 40 meter antenna on the top of a telescoping steel pole. The base of the pole was on the ground, and when the ground was wet and the pole extended to a quarter-wavelength, the pole started resonating and changed the radiating resistance of the short dipole and, consequently, the vswr which is normally kept low (1:1 at the center-tuned frequency in the vertical position when optimum adjustment is achieved).



The experience with the radiating support, of course, is indicative of what can happen with any portable antenna. It is subject to variations in characteristics when brought near other objects with nearly the same frequency of resonance. When the lower end of the telescoping steel pole was insulated from the ground, it was possible to extend it to any height (within its 40 ft capacity) without changing the tuning of the antenna. Of course, this was with the antenna in the vertical position. With the short dipole in the horizontal position, it could be expected to change its characteristics as its height was changed due to imaging in the ground.

The possibilities of experimenting with antenna height vs propagation effects on the 40 and 80 meter bands with small lightweight antennas of this type are excellent since they require only lightweight supports and may be easily mounted in either the horizontal or vertical positions down to a very small fraction of a wavelength from the ground. The 40 meter dipole worked very well 6 ft above the ground and could undoubtedly be used even lower. This was in the vertical position which, with a half-wave dipole, would put the current node 40 ft off the ground (instead of 8 ft). In the horizontal mode, both the 4 ft antennas on 40 meters and the 8 ft antenna on 80 meters have been mounted directly to a steel mast with right-angle clamps with good results. The clamps were placed close to the center of the straight dipole section and on the same side to which the coax shield was connected.

One of the first questions asked is whether multiband operation is possible with these short dipole antennas. First, the antennas may be tuned to the odd harmonics of the fundamental frequency of the

DUAL GATE MOSFET

PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.
to 400 MHz. $29.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

to 300-450 MHz.
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

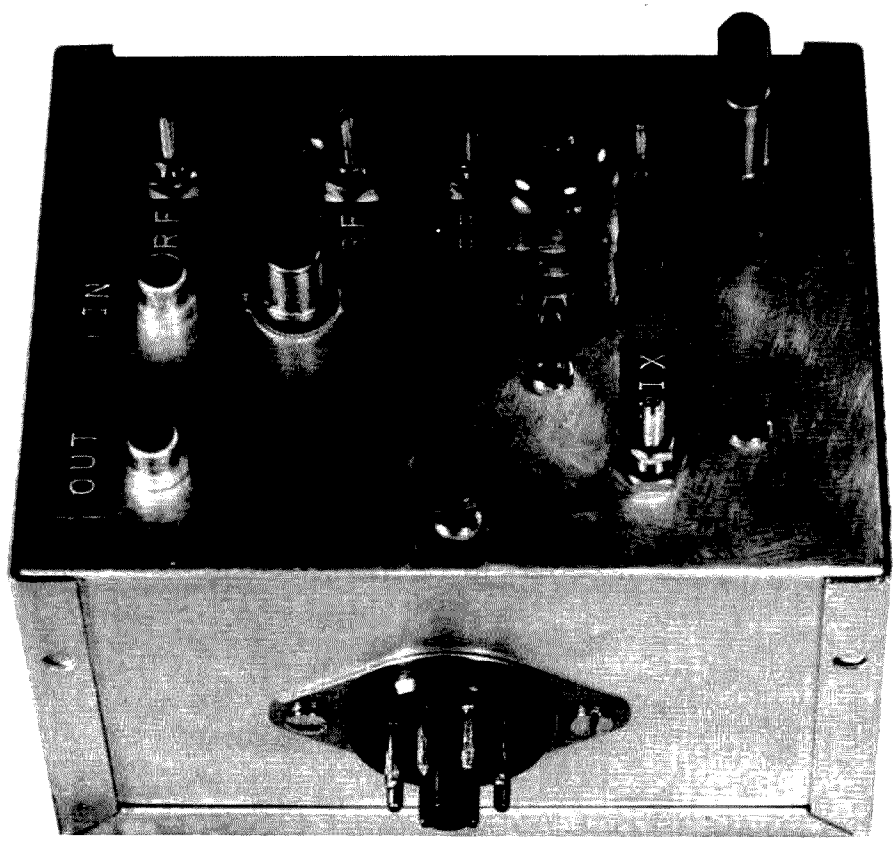
EPSILON RECORDS

206 East Front Street, Florence, Colorado

antenna. Thus, the 4 ft dipole for 40 meters worked very well on 15 meters. One 2 ft dipole for 15 meters and 20 meters tuned to a low vswr on 6 meters.

The 2 ft dipole for 15 and 20 meters contained a trap in each coil to permit operation on the two bands. Fine adjustment in both bands was accomplished by adjusting taps on the inside turns of the end loading coils. The coils tune sharply, much like mobile antennas, as the radiating resistance is low and the overall Q of the antenna is high. It was found that with the 18 in. dipole for 15 meters, the entire phone band could be tuned with my SBE Model 34 transceiver. However, the 4 ft dipole required adjustment to cover the entire phone band on 40 meters, as when tuned 1:1 at the center of the phone band, the vswr at 7.2 and 7.3 MHz was about 3:1. An experimental remote tuning device with a reversible motor was built and operated on 40 meters. This device permitted tuning right "on the button" on both 40 and 15 meters.

The coil dimensions for 15 meters are 7-3/8 by 7-3/4 in., and the turns are purposely made wider in the center where the current is higher. The inner conductor (first turn) is 1/4 in. wide, and the next two graduations in conductor width are supposed to be 3/16 and 1/8 in. respectively. On the left side may be seen the tuning stub, which is a 1/16 in. O.D. brass tube which slides in a larger tubing. The larger diameter tubing is soldered to the end of the printed circuit coil.



Three 4 ft dipoles were wide-spaced 6 ft above the ground to form a beam. As they were fixed and could not be rotated, the direction of the beam was changed by running out and quickly interchanging the director and reflector or front and back dipoles. The beam seemed to have a good front-to-back ratio, but the gain was not checked. It appears that two or three such dipoles on a boom might be great for 40 or 80 meters. They could be used as a rotatable beam either with horizontal or vertical polarization. This could be changed remotely by a motor drive, which should lead to some interesting experiments in propagation effects.

Tuning these antennas requires some type of instrumentation to determine optimum operating conditions. The minimum should include at least a vswr meter. The antennas should be tuned so that near zero or very low reflected power is in evidence. If the center matching impedance is proper, the only tuning required is to adjust the two coils until the antenna is resonant at the operating frequency. Then the vswr should be near 1:1. Initially, if the matching impedance is a little off, it may not be possible to bring the reflected power down near zero, but a low point will be found indicating resonance has been achieved. Increasing or decreasing the matching impedance should then permit achieving a low vswr. Retuning the coils may be necessary if a large change is made in the center matching impedance.

A grid dip meter or other instrument such as the Omega-t Systems antenna noise bridge can come in handy to find out the resonant frequency of the antenna before tuning. The antennas are generally made with slightly longer coils than necessary to permit adjustment to various conditions. The 18 in. dipole for 15 meters has a jumper from the center conductor to the first turn to bring the antenna into tuning range. The jumper is a piece of bare copper wire soldered at the ends.

For the amateur who likes to experiment, or the amateur with limited space for antennas, these antennas have many interesting possibilities. For the amateur who has everything, one for portable use, or maybe for use just for the fun of shocking someone by saying, "I'm using a 4 ft dipole antenna on 40 meters," may be the order of the day. . . . K9LGH■

HIGH PERFORMANCE CONVERTER FOR 6

Alan Wilson WA9HES
308 East Wood Street
Hillsboro IL

Been looking around frantically for one of the good old converter circuits? Here's one that uses a Nuvistor for high gain and low noise on 6 meters.

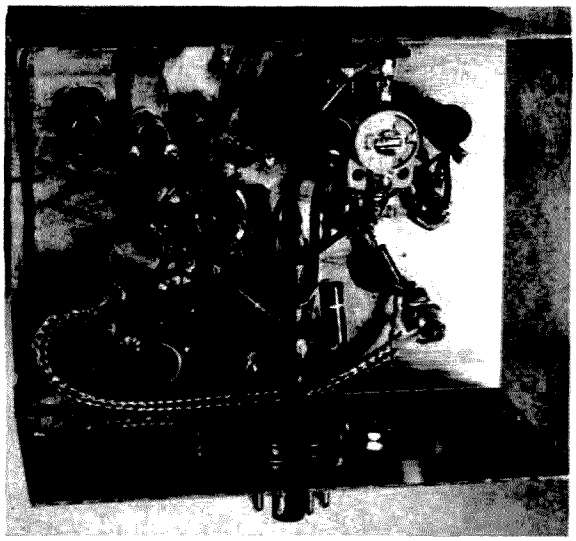
The first addition to my 6 meter station was the converter described below. The unit is designed with the idea of obtaining high performance with a minimum of circuitry. I will attempt to describe the unit in such a way that it can be easily duplicated.

Circuit

A 6CW4 Nuvistor serves as the rf amplifier. Oscillator and mixer functions are provided by a single 6U8A. The 6CW4 must be neutralized, but the low noise figure obtained by the use of this tube makes the extra effort worthwhile. The pentode section of the 6U8A is utilized as the mixer. This arrangement provides adequate output for any reasonably sensitive receiver.

The oscillator uses the triode section of the 6U8A. A third overtone crystal determines the frequency. In my unit a 43.2 MHz crystal gives coverage from 50.2 to 50.5 MHz using the 40 meter band as an i-f. Other crystal frequencies could be used to cover other segments of the band, or if a general

coverage receiver were employed, a 43.0 MHz crystal would cover the entire band with output between 7 and 11 MHz.



Construction

In order to obtain optimum results the converter should be built in accordance with good VHF practices. All components should be mounted rigidly, keeping the leads as short as possible. Prewound Miller coils are used throughout. Note that the mixer output coil is from the 21A000RBI series. A coil of the same inductance but from the smaller 20A000RBI series would not allow for winding the output link. I used silver mica capacitors for all tuned circuit and coupling purposes. Small tubular ceramics would serve as well. All bypassing is done with 1000 pF ceramic discs.

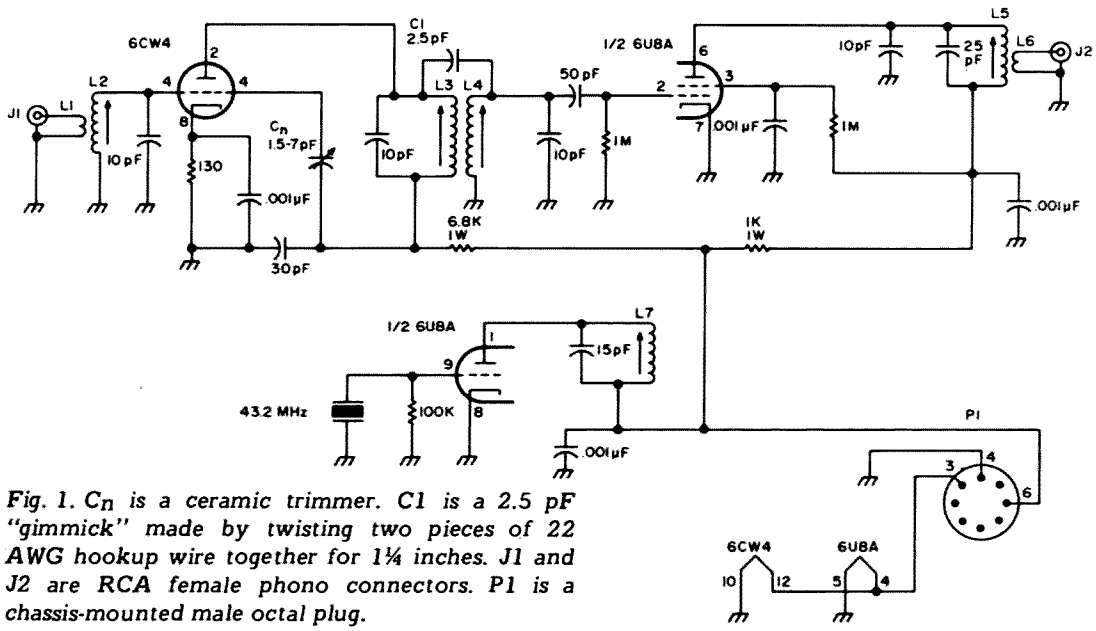
The only critical part of the converter is the neutralization circuit. The 1.5-7 pF neutralizing capacitor must be secured solidly. The body of the 6.8 kΩ resistor should be positioned as close to the lower end of L3 as possible. This is necessary because the resistor has a dual purpose. It functions not only as a series dropping resistor but also serves to keep the bottom of L3 above ground.

Tuneup Procedure

The first step after applying power is to adjust L7 for maximum rf output as indicated by a grid dip meter in the wavemeter

The rf stage with the associated neutralizing circuitry is at the upper left. Output from the mixer is coupled to J2 via a length of RG-58/U.

position. Next, connect a short length of wire to J1 and set the grid dip meter to generate a 6 meter signal. Now connect the converter to the receiver with a short piece of coax and adjust L5 for maximum signal as indicated on the receiver's S-meter. Next, set the neutralizing capacitor at midrange and tune L2, L3, and L4 for maximum signal strength. Now disconnect the 6.8 kΩ resistor from the high voltage source and adjust the neutralizing trimmer for *minimum* signal as noted on the S-meter. Finally, reconnect the resistor and repeak all five coils. The converter is now set for near optimum performance.



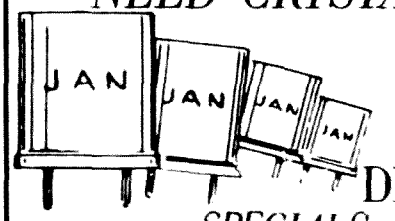


Fig. 1. C_n is a ceramic trimmer. C1 is a 2.5 pF "gimmick" made by twisting two pieces of 22 AWG hookup wire together for 1¼ inches. J1 and J2 are RCA female phono connectors. P1 is a chassis-mounted male octal plug.

Power Supply

The power source used should supply +150V and 6.3V with minimum current ratings of 50 mA and 750 mA, respectively. The high voltage should be regulated. In my application a single OD3 regulated supply serves both the 6 meter converter described here and a similar 2 meter converter. The high voltage is continuously on in both units at all times, and the filament voltage is applied to the converter in use.

Coil Data

L1	3½ turns No.22 insulated over L2
L2, L4	Miller 20A687RB1
L3, L7	Miller 20A827RB1
L5	Miller 21A155RB1
L6	5 turns No.22 insulated over L5

L3 and L4 spaced ¾ inch center to center

Results

After using the converter for several months, I am completely satisfied with its performance. At no time have I experienced problems with stability or the "birdies" commonly encountered in VHF converters. When the band is open the converter pulls in the weak ones, yet does not suffer from cross-modulation effects with the locals. If you build the converter as shown, I am sure that you will be thoroughly pleased. Be seeing you on 6.

How to get into one of today's hottest money-making fields—*servicing 2-way radios!*

More than 5 million two-way transmitters have skyrocketed the demand for service men and field, system, and R & D engineers. Topnotch licensed experts can earn $12,000 a year or more. You can be your own boss, build your own company. And you don't need a college education to break in.

HOW WOULD YOU LIKE to earn $5 to $7 an hour... $200 to $300 a week ... $10,000 to $15,000 a year? One of your best chances today, especially if you don't have a college education, is in the field of two-way radio.

Two-way radio is booming. Today there are more than *five million* two-way transmitters for police cars, fire trucks, taxis, planes, etc. and Citizen's Band uses—and the number is growing at the rate of 80,000 per month.

This wildfire boom presents a solid gold opportunity for trained two-way radio service experts. Most of them are earning between $5,000 and $10,000 a year *more* than the average radio-TV repair man.

Why You'll Earn Top Pay

The reason is that the U.S. doesn't permit anyone to service two-way radio systems unless he is *licensed* by the FCC (Federal Communications Commission). And there aren't enough licensed experts to go around.

This means that the available licensed expert can "write his own ticket" when it comes to earnings. Some work by the hour and usually charge at least $5.00 per hour, $7.50 on evenings and Sundays, plus travel expenses. Others charge each customer a monthly retainer fee, such as $20 a month for a base station and $7.50 for each mobile station. A survey showed that one man can easily maintain at least 15 base stations and 85 mobiles. This would add up to at least $12,000 a year.

How to Get Started

How do you break into the ranks of the big-money earners in two-way radio? This is probably the best way:

1. Without quitting your present job, learn enough about electronics fundamentals to pass the Government FCC License. Then get a job in a two-way radio service shop and "learn the ropes" of the business.

2. As soon as you've earned a reputation as an expert, there are several ways you can go. You can move out, and start signing up your own customers. You might become a franchised service representative of a big manufacturer and then start getting into two-way radio sales, where one sales contract might net you $5,000. Or you may be invited to move *up* into a high-prestige salaried job with one of the same manufacturers.

The first step—mastering the fundamentals of Electronics in your spare time and getting your FCC License—can be easier than you think.

Cleveland Institute of Electronics has been successfully teaching Electronics by mail for over thirty years. Right at home, in your spare time, you learn Electronics step by step. Our AUTO-PROGRAMMER® lessons and coaching by expert instructors make everything clear and easy, even for men who thought they were "poor learners."

Your FCC License... or Your Money Back!

By the time you've finished your CIE course, you'll be able to pass the FCC License Exam with ease. Better than nine out of ten CIE graduates are able to pass the FCC Exam, even though two out of three non-CIE men fail. This startling record of achievement makes possible our famous FCC License Warranty: you'll pass the FCC Exam upon completion of your course or your tuition will be refunded in full.

Find out more. Mail the bound-in post-paid card for two FREE books, "How To Succeed In Electronics" and "How To Get A Commercial FCC License." If card has been detached, use coupon below.

ENROLL UNDER NEW G.I. BILL

All CIE courses are available under the new G.I. Bill. If you served on active duty since January 31, 1955, or are in service now, check box on card for G.I. Bill information.

CIE Cleveland Institute of Electronics
1776 East 17th Street, Cleveland, Ohio 44114

Please send me without cost or obligation:

1. Your 44-page book "How To Succeed In Electronics" describing the job opportunities in Electronics today, and how your courses can prepare me for them.
2. Your book on "How To Get A Commercial FCC License."

He's flying high. *Before he got his CIE training and FCC License, Ed Dulaney's only professional skill was as a commercial pilot engaged in crop dusting. Today he has his own two-way radio company, with seven full-time employees. "I am much better off financially, and really enjoy my work," he says. "I found my electronics lessons thorough and easy to understand. The CIE course was the best investment I ever made."*

Business is booming. *August Gibbemeyer was in radio-TV repair work before studying with CIE. Now, he says, "we are in the marine and two-way radio business. Our trade has grown by leaps and bounds."*

from BREADBOARD *to* Printed Circuit *the easy way*

. . . . . a sneaky system that gives you "professional" boards fast !

How many times has a particular circuit caught your attention and interest only to be passed by because you didn't have the exact components and you felt that you didn't want to put all the work into constructing it if there was a chance that you might not be able to get it to function? Perhaps the thought of changing various parts and having extra holes in the finished product deterred you. Many people, myself included, like to construct an item once and have it work properly with minimum changes. The more complex the circuit or meticulous the work, the less I like to make changes.

Since the average junkbox seldom yields all the specified components for any project, how are we to avoid unnecessary effort in construction projects? After many miles of solder joints a method has evolved which I believe is the most direct route from circuit to finished product, be it chassis or printed circuit board.

Breadboarding

The first step was to evolve a minimum-effort method of breadboarding a circuit, particularly eliminating drilling, mounting, and hardware wherever possible. An arrangement was sought whereby minimum material was used and this material could be used over, time and time again for other circuits. Another requirement was that the method be consistent with good VHF wiring techniques.

What followed was an extremely simple system consisting of two basic components, a piece of copper-clad printed circuit board, and a quantity of inexpensive miniature terminal strips. The board can be purchased at almost any electronic supply house or from any number of mail order firms for about $2 a square foot. The miniature terminal strips are also inexpensive.

At first a selection of multilug strips were purchased as well as the single-lug strips; however, after many projects if was found that the multilug strips were seldom used as most circuits were constructed with the single-lug strips. The miniature terminal strips are a lot easier to work with than their normal sized predecessors, and enable you to get a higher component density for a given area of copper-clad board.

The method is simple to use; merely decide where on the board a connection is to be made between two conductors and simply solder down the foot of the terminal strip in that spot (see Fig. 1).

Conductors to be grounded are soldered directly to the board. In this manner the entire circuit is constructed and changes require only the resoldering of a terminal lug. I usually keep my component leads as long as the circuit considerations will allow; after completion of the breadboard phase, I can unsolder everything. The components are then used in the actual finished product and the terminal lugs can be used again. I am still using the same dozen lugs that I originally purchased five years ago!

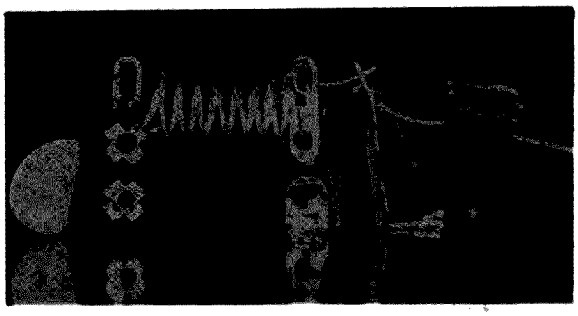

Fig. 1. Terminal strips simplify prototyping because of the ease with which they can be soldered to a copper-clad printed circuit board. (Photo by G. Gfrerer.)

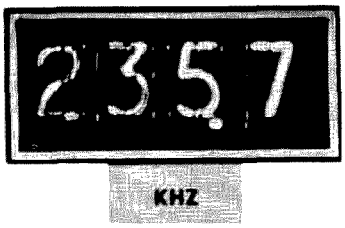
PC Construction

Once an operable circuit is realized, you will no doubt wish to put it in some finished form. The most common packaging technique is the printed circuit mounting arrangement. This appears to be a lot of work to the average person, and most of the "simple" methods described in articles on the subject tend to leave doubt in readers' minds.

After trying many methods I found a way which satisfied these basic requirements:



- Only one chemical required
- Minimum artwork
- Minimum time between circuit and printed board
- Capability of small quantity production if desired
- Ability to directly utilize PC layouts already in magazine articles

The key to the entire system is a flexible clear plastic sheet which has adhesive on one side. This is sold as an inexpensive method for plastic laminating of documents. One large envelope contains two 8 x 12 in. pieces for 99¢.*

If you would like to build an item from a magazine article and the author has printed the artwork for his board, you're home free. Cut the artwork out, and stick one or two layers of laminating plastic on each side of it. Take a razor blade and cut out all of the conductor areas and remove them. You now

SIGNAL/ONE'S CX7 GIVES YOU

Electronic counters belong in the laboratory . . . because they're big, expensive, precision instruments . . . right? So what's one doing in the CX7? Well, it gives you . . . . . .

- CALIBRATION ACCURACY OF 100 HZ at every point in every band
- READOUT DIRECT TO 100 HZ . . . without interpolation
- LIFETIME PRECISION . . . free of error due to aging or environment
- BIG, BRIGHT DISPLAY . . . virtually impossible to mis-read

SIGNAL/ONE engineers did it by putting state-of-the-art technology to work in a precision counter no larger than a small book. This remarkable unit actually counts each individual cycle of VFO output during a precise (crystal-controlled) 1/100 second time interval . . . and displays the last four digits of the total on an electronic readout. (For example, a VFO frequency of 3521.7 kHz (3,521,700 cycles/second) yields a 1/100 second count of 35,217 . . . and the display shows 521.7 kHz). The readout is as accurate as the 1/100 second timing. Timing is derived digitally from the 100 kHz reference standard. So, by simply zero-beating the 100 kHz oscilator to WWV (or a BC station) you automatically calibrate the VFO to 100 Hz accuracy . . everywhere.

"It Speaks for Itself"

signal/one

A Division of ECI (An NCR Subsidiary)

St. Petersburg, Fla. 33710

have a piece of plastic laminated paper with holes in it, which we will call a mask.

Cut a piece of copper-clad board to size and place the mask on the board. Use a couple of small alligator clips to keep the mask from moving position. Take a can of opaque spray lacquer (any color), and using minimum paint, spray the board and mask. The board and mask should be lying on a flat horizontal surface, and you should be spraying straight down.

Be sure to shake the paint thoroughly and hold it about 12 in. away from the board. Some practice may be necessary in spraying to keep the paint from running. The job may be done with a series of light sprayings with about 5 min. drying time between. Once you have finished spraying, lift the mask up vertically from the board to avoid smearing the paint.

After allowing the painted surface to dry 30 min. we can correct any feathered edges in the painted areas. These will sometimes occur to varying degrees because the mask will not usually lay perfectly flat on the board. This can be alleviated to some extent by using more layers of plastic on each side, but it then becomes more difficult to cut the mask. A sharpened ink eraser will easily rub away smears.

After the board is prepared to your satisfaction, immerse it in a plastic or glass tray of ferric chloride or iron perchloride. These solutions are now commonly sold in supply houses under the description of "etchant."

The etching time will vary with the strength of the etchant, its temperature, the thickness of the copper layer, the amount of agitation, etc.

Once the unpainted copper has been completely etched away, remove the board from the solution. But be especially careful to avoid getting any acid on you or your clothing! Carefully wash the board with lukewarm water and soap.

The lacquer may be removed by a variety of means. The easiest way is to brush on lacquer thinner, which removes it very quickly. Or it can be removed with steel wool or a kitchen scouring pad.

The remaining copper should be coated with solder to protect it from corrosion.

This also builds up the conductive cross section. Do this with 60/40 solder and a soldering iron. After depositing the solder, wash off excessive resin from the board with lacquer thinner.

The only remaining steps are to drill holes in the board at the appropriate spots for the component leads, and the actual mounting and soldering of the components themselves. The mask may be stored and used to make future copies of the circuit board, if needed.

What we have done so far is perhaps the easiest method, that of using an already existing conductor layout. Only a few additional steps are needed to design an original layout. Plan the conductor pattern on a sheet of quadrille graph paper (8 x 8 squares to the inch), drawing in the symbols for the components, actual size. Transfer the conductor pattern below the drawing on the same page and use this as your mask, saving the original as a guide to drilling holes and installing actual components in the board.

High-Density Packaging

Sometimes we may wish to get a large number of components in a small volume, or our circuit has many conductor crossing points and does not lend itself well to printed circuitry. Classic "chassis" construction can be ruled out because by using such things as transistor sockets you have most of the components under the chassis, and the socketed components, transistors or whatever, protrude from the top. This dimension from the top of the chassis can be eliminated and a saving in space realized.

Fig. 2. With a copper-clad board as a base plate, very high-density packaging can be achieved by mounting bulky components, such as miniature relays, i-f cans, and crystals, on their sides. This receiver section packs 90 components within the volume of a 3 x 5 in. board! (Photo by G. Gfrerer.)

HAM HOSPITALITY

How about Johannesburg?

Dan Mahony ZS605 offers his home for visiting U.S. hams. His address is 88 Milton Road, Lombardy East; telephone 608-1454. Area: 1 acre. (9½ miles southwest of Johannesburg Centre. Children welcome!

Accommodations: Guest room with private bath. Ham shack makes nice spare bedroom for junior ops.

Reciprocity: 1 day, particularly in California area.

Limited Ham Hospitality

David G. Flinn, Starlane Farms, Ridge Road, Ludlowville, New York 14862.*

English speaking DX and U.S. hams welcome. Plenty of advance notice requested. We have two boys (ages 6 and 8) and 330 acres. Overnight accommodations are 10-15 miles away, but we could put up 1 or 2 people in an emergency. Interests are flying, model railroading, music, and art. Wife's tastes: weaving, crafts, music, art. Particularly interested in meeting Rotarian hams.

*Ed. Note. Dave Flinn is owner of Stellar Industries (ham equipment dealer and 73 advertiser).

My home will be open to visiting DX Hams.
William G. (Jerry) Allnoch WA4TST
507 Pinecone Street
Waycross, Georgia
(912-283-0285)

Hospitality offered: meals, snacks, and possibly overnight accommodations, if they don't mind sleeping on a couch in the livingroom.

George Pataki YO2BO/2
34-24 76th Street
Jackson Heights, N. Y. 11372
(212-639-3195)

Visiting DX'ers: Tour CBS, visit radio clubs, meet other hams. I'll serve as your guide around town.

The technique is simple. Using a piece of copper-clad printed circuit board as a base plate, mount all sockets and major components such as i-f cans on their sides. An example of this is the i-f section of a receiver, such as that shown in the photo of Fig. 2. The transistor sockets are epoxied to the board and the i-f cans are soldered to it. The minor components are then soldered onto the terminals of the sockets and i-f cans as required. An inherent disadvantage to this type of system is that it is not as rugged and cannot take as much physical abuse as a printed circuit.

It is hoped that this discussion will give some ideas to experienced builders, and encourage the novice to delve deeper into this rewarding hobby.

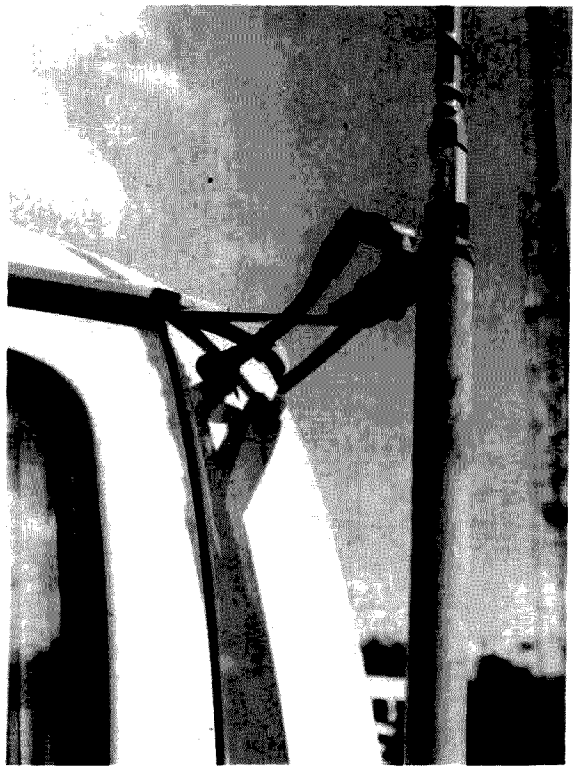
THE CAMPER: Mobile and Portable

More than just a mobile, the camper can become a base station on wheels.

One of the things I was anticipating with joy when I took an early retirement was the additional time that I could spend operating my rig. Unfortunately, I also enjoy traveling, so, during two years of retirement, my wife and I spent only seven months of this time at home. Some of our traveling was done overseas, but that which we did in the States was primarily done in our VW camper. With the advent of the many deluxe overnight trailer and camper parks throughout the country, traveling in a VW camper allows one to do a maximum amount of traveling at a minimum of cost, a must when living on a retirement income! So now our problem was how to enjoy traveling and ham radio at the same time. One of the things that spurred us on to find a solution was the fact that our son, in Thousand Oaks, California (W6GST) is also a ham and enjoys following us on our trips via ham radio. Here's how we worked it out.

The ambient noise level in a VW camper is relatively high, particularly when driving at high speeds. Also, the available space below the instrument panel is rather limited. We decided that we would limit our mobile operating to Citizens' Band and operate the amateur bands on a portable basis. The first problem to be solved was the antenna mount. The standard ones available didn't seem to have the desirable mechanical strength to allow us to mount a variety of antennas (including a full-length telescoping vertical for 40 meters. With the use of stainless steel (ordinary plated steel or brass could be used) and some plastic rod, I concocted the mount shown in Fig. 1. We normally drive using the Citizens' Band for on-the-road communications (Fig. 2). It is surprising how many of the long-haul truck drivers have CB units in their truck cabs. They are usually most anxious to carry on a conversation, particularly when they are driving the lonely open stretches out west. In addition to providing a delightful pastime while driving, CB communication can be rewarding. Some gas station chains on our major interstate highways constantly monitor Channel 9, which makes them available in case one runs out of gas, has a flat tire or other mechanical trouble, or—most important—in case of emergency. The Heathkit CB transceiver was mounted as shown in the photo without any interference with the driving controls. It was simple to trim the antenna to its proper length with the help of a vswr meter and the ground plane area provided by the large area of the VW camper roof gives about a 5 mile range for reliable mobile operation with enough volume to overcome the ambient engine noise.

For operating portable in the ham bands, I selected appropriate Heliwhip antennas, wound and tuned at the factory for my selected favorite frequencies; however, they are fairly broadbanded and allow operating over a spectrum either side of the specified frequency. I'm sure a Hustler or some other multiband antenna will be just as satisfactory, and it is just a matter of personal preference. At home, I use the Heathkit SB-301, SB-401, SB-200 combination, and we chose the SB-100 and the Kompact Kilowatt HA-14 for use in the camper. The



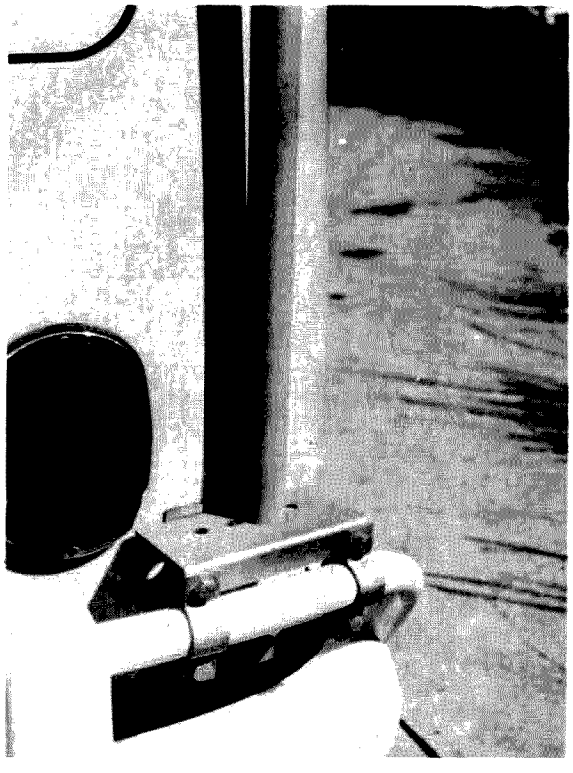


Fig. 1. Homebrew mount places antenna high above the street, yet is stable and electrically sound.

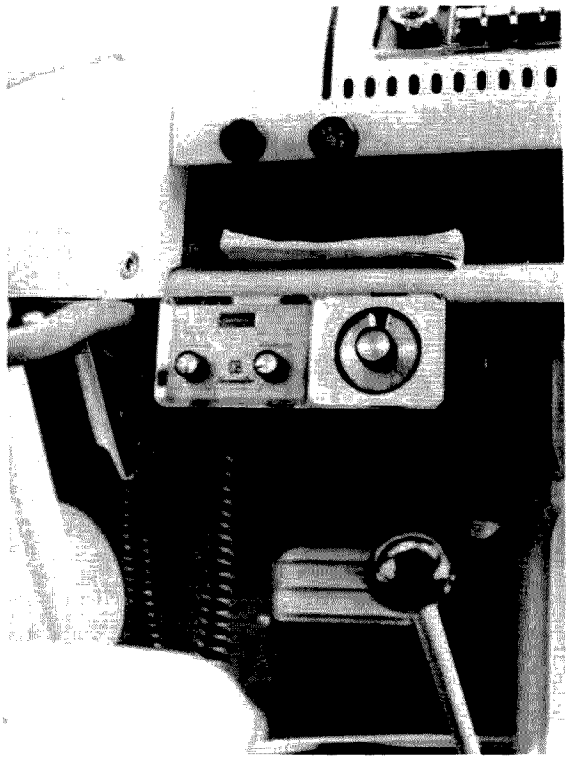

Fig. 2. On the open road, the Heathkit CB transceiver keeps us in touch with the world. It is comforting to know that one CB channel is monitored on a national scale by many of the gas station chains.

combination icebox and portable sink which is standard equipment in the camper was removed and replaced with a foam ice chest purchased for 88¢ and a plastic water jug costing less than one dollar. These are stowed in any convenient place in either the trailer and camper, and to us are actually more convenient and flexible than the original equipment. The space vacated by the icebox provided an excellent place to mount the radio equipment. To make the installation neat and stable we constructed a rack (Fig. 3) from some old plywood that many years ago had done duty as a Ping Pong table. As shown in the photo, adequate ventilation must be provided by drilling as many holes as possible without impairing the strength of the rack.

Wooden stops are positioned behind the two rear rubber feet of the Kompact Kilowatt, the transceiver, and the power supplies. This prevents them from sliding to the front (rear of the rack); large washers, with off-center holes drilled in them, screwed to the front of the rack, prevent movement in the opposite direction. The height of the shelves is such that if the equipment should bounce, it will still be held captive by the stops and screwed-on washers. The bottom of the rack holds a Honda 300W gasoline engine power supply. This unit is very quiet in operation and surprisingly light in weight, considering its output capability. This unit also delivers 12V dc for battery charging in case of emergency. I drilled a small hole to run the coax from the antenna inside the camper. The hole was then sealed with a plastic rubber sealer compound. This made a perfectly waterproof joint. Though most of the private trailer parks include free electricity, some of the state and national parks do not. When juice is available, of course we use it, and this allows us to use the full kilowatt. When the gasoline power supply is used, we operate barefoot. It is quite a sensation to be sitting on the side of the highway talking to someone several thousand miles away and get 20-over-9 reports.

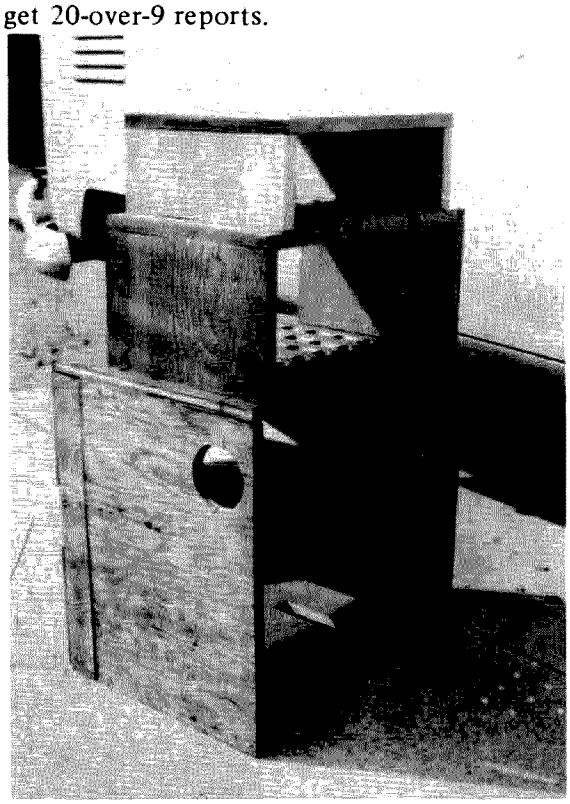

Fig. 3. Equipment rack replaces icebox of original camper. Lots of air holes help to dissipate the heat generated by the units.

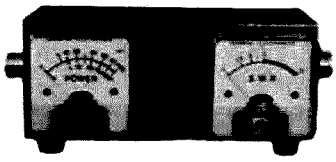

I'm sure my wife would rather leave the cooking equipment home than the radio equipment—especially when we have a schedule with our son.

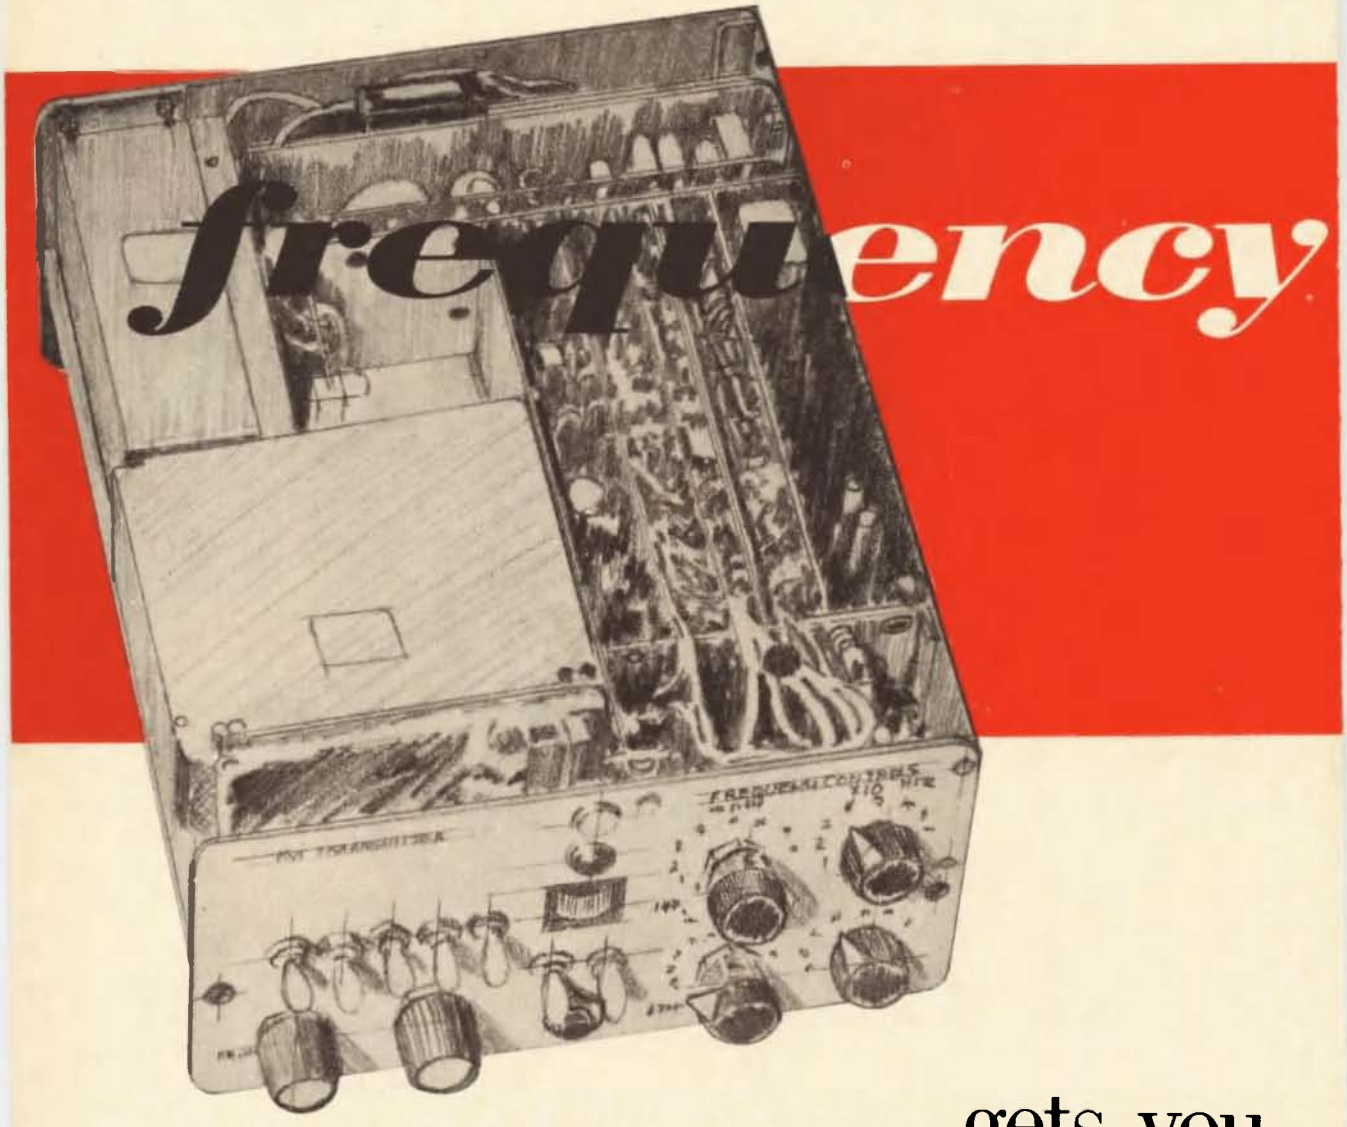
You Think You Have Troubles?

Take the case of Charlie Damico W3VXO. Charlie is one of our sightless hams. However, he has not allowed his handicap to get in his way. He is employed in electronics, repairs all his own gear, with few exceptions, can rig up an antenna without help, and seems to get along just fine.



A few months ago, he began getting TVI complaints from one of his neighbors. This fellow (who lives in the City of Brotherly Love, incidentally) really got hot under the collar and began circulating a petition around the neighborhood.

The FCC stepped into the picture and investigated the complaints. After finding that Charlie was putting out a clean signal and was not creating interference on a good TV set, a committee questioned the 20 signers of the petition to find that 14 of them thought they were signing a petition for someone running for Mayor of Philadelphia. Of the remaining six, four had had no interference, but were friends of the original complainant; the remaining one was willing to drop the subject upon installation of a highpass filter. So, Charlie was left with one irate neighbor.

One would think this would be the end of the story. Unfortunately, this was not the case. One night, Charlie came on the air and said, "You know, something seems to be wrong here. I'm not getting the right readings on the output of this rig, and I can't figure out what might be wrong." We all noted that his signal was not up to its usual strength, but he was still readable. After checking his swr, he came to the conclusion that something was wrong in the antenna. He left the air. The following night he told us the story. *Someone had cut his coax feedline to his 75 meter dipole.*

Charlie had gone up to the roof and strung a Marconi antenna to get back on the air.

with just one crystal!!

Gil Boelke shows how it's done...

synthesis

the modern way to control frequency

by Gilbert Boelke W2EUP

A complete and comprehensive article covering theory and techniques of indirect frequency synthesis, plus schematics and a description of a practical 400-channel synthesizer used in a two-meter FM transceiver with only one frequency-determining crystal.

I
THE PROCESS

Frequency synthesis is the term used to describe the process of synthesizing (or "putting together") many frequencies from a small number of starting frequencies. In theory, any number of channels may be so generated from only one master oscillator, using the electronic techniques of adding, subtracting, multiplying, and dividing frequencies. In practice, the larger the number of channels the more worthwhile it is to go the synthesizer route.

A *direct* synthesizer uses such conventional techniques directly, filtering the undesired output products at each step in the process. This technique has the disadvantage that many high quality filters are required to reduce the undesired (spurious) output frequencies to the desired extent.

An *indirect* synthesizer uses a voltage-controlled oscillator to generate the output signal, electronically "steers" it to the correct frequency and "locks" it there. Its main advantage is that the output needs no filtering; it comes from an on-frequency oscillator. All spurious products are kept within the confines of the synthesizer loop (with any luck) and do not appear in the output.

Figures 1 and 2 illustrate two ways a synthesizer can be used. In Fig. 1, the synthesizer covers the full range of transmitter and receiver frequencies for a General Electric TPL unit. An extra X8 multiplier must be added to the receiver so that both re-

* 505 Main Street West Seneca, New York 14224

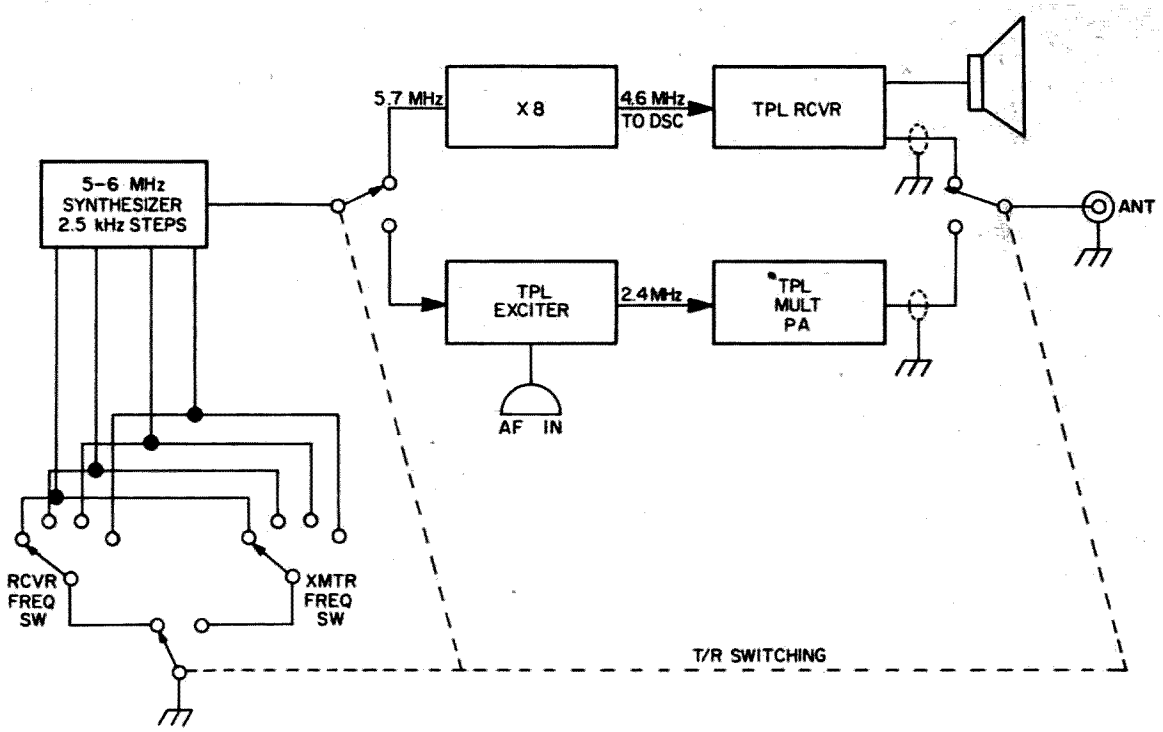

FIG. 1 How to use synthesizer for 60 kHz incremental switching in existing units

ceiver and transmitter multiply the synthesizer output by 24, to make channel spacing the same for both receiver and transmitter.

Although a synthesizer could be built as a crystal oscillator substitute for existing types of equipment, it can be more effectively exploited in a "start from scratch" design, as shown in Fig. 2. True FM can be produced by direct modulation of the synthesizer, eliminating the need for a phase modulator or frequency multiplication to build up the deviation level. Or, as a receiver local oscillator, a synthesizer can just as well be designed to deliver the oscillator injection frequency directly, eliminating the need for frequency multipliers.

Figures 3 and 4 show block diagrams representing the synthesizers used in Figs. 1 and 2. The synthesizer block diagram of Fig. 3 generates 2.5 kHz steps in the 6 MHz range. Used to drive existing transceivers, this arrangement produces 60 kHz steps in the two-meter band. If the range is extended to 5.7 MHz and the output multiplied by 24, the same synthesizer can be used for the receiver.

Addition of a mixer and a multiplier as in Fig. 4 makes it possible to generate 60 kHz steps directly in the two-meter band. A separate crystal oscillator is used to heterodyne the output signal down to a frequency suitable for division. By switching crystals — in this case to 141 MHz — the synthesizer output can be moved down 9 MHz to provide oscillator injection for a receiver having a 9 MHz i-f. These mixer injection frequencies could also be obtained by suitable means from the basic reference oscillator, rather than adding two more crystals.

How it Works

Consider the simplified synthesizer of Fig. 5. This example is for a 5 — 6 MHz output range in 10 kHz steps. A tunable VCO (voltage-controlled oscillator) is used to generate the output signal; in doing so, of course, it must tune electronically from 5 to 6 MHz by varying the dc input voltage. The stability of such an oscillator doesn't even begin to match that of a crystal oscillator, but it *does* have the flexibility of operating on any channel in the desired range. So the remainder of the circuitry is devoted to detecting the VCO frequency,

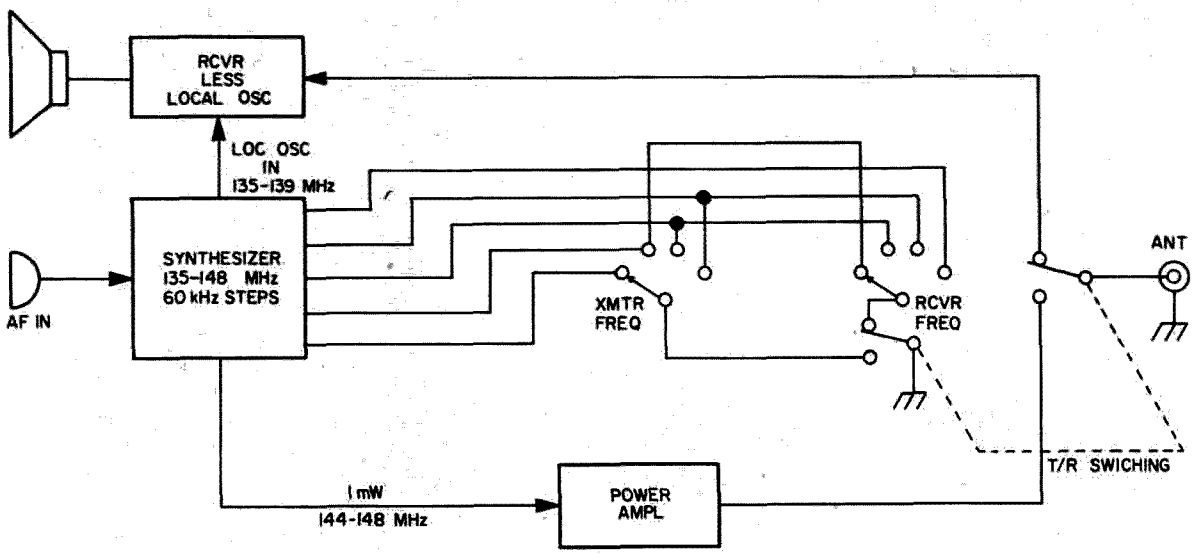

FIG. 2 Synthesis of local oscillator and transmitting frequencies eliminates frequency multipliers and greatly simplifies receiver design

relating it to the *desired* frequency, and adjusting the oscillator *electronically* to it.

Spacing of the output steps is determined by the reference frequency. In this case, a 10 kHz reference means that the circuit can lock to any harmonic of 10 kHz such as 5.000, 5.010, 5.020, 5.030 . . . etc. to 6.000 MHz. Direct multiplication could be used to get the same result, but it would be nearly impossible to eliminate undesired harmonics of the 1 kHz signal, even with the best of filters. So, instead of multiplying 10 kHz to, say, 5 MHz, start with the VCO at (or near) 5 MHz and divide it by 500 instead. This function is accomplished in the programed divider ($\div n$, or "divide-by-*n*"). Consisting of a chain of flip-flops, this circuit can be programed to divide by any ratio between 500 and 600. When it divides the 5 MHz output of the VCO by 500, the result is 10 kHz.

The phase detector circuit compares the $\div n$ output to the reference signal, delivering a dc output proportional to the phase difference between them. This dc level controls the VCO. When the VCO output drifts from exactly 5 MHz, the output of the $\div n$ will drift in exact proportion to it since it always is 1/500th of the output signal. The phase detector sees this as a phase change and shifts its dc output to the phase detector immediately to steer it back to 5.000 MHz exactly. Since it compares phase instead of frequency, the frequency at the $\div n$ output is never permitted to shift so much as one hertz either way, and the output of the VCO is held precisely to 5.00 MHz. *Frequency accuracy depends only upon the stability of the reference frequency oscillator.*

To change frequency to 5.760 MHz it is only necessary to change the *divide* ratio of the $\div n$ circuit by switching the programing inputs of the $\div n$. Since this is a larger divide ratio than 500, the $\div n$ output will at first be below 10 kHz. The phase detector senses this shift as a phase change in the very first cycle following the shift and immediately starts action to correct it. When the correction is complete, the $\div n$ output is again on 10 kHz, but the VCO is on 576 X 10 kHz, or 5.760 MHz.

The synthesizer of Fig. 3 is only a little more complicated than the basic unit of Fig. 5 . Since 2.5 kHz steps are desired, the reference frequency must be 2.5 kHz. Stable crystals of this frequency are not notably practical, so a 1 MHz master oscillator is used, divided down to 2.5 kHz by a series of flip-flops. A harmonic of the 1 MHz signal is conveniently adjusted to zero-beat with WWV, thus precisely aligning all channels to frequency. A higher divide ratio is necessary in the $\div n$ circuit due to the lower reference frequency, as shown.

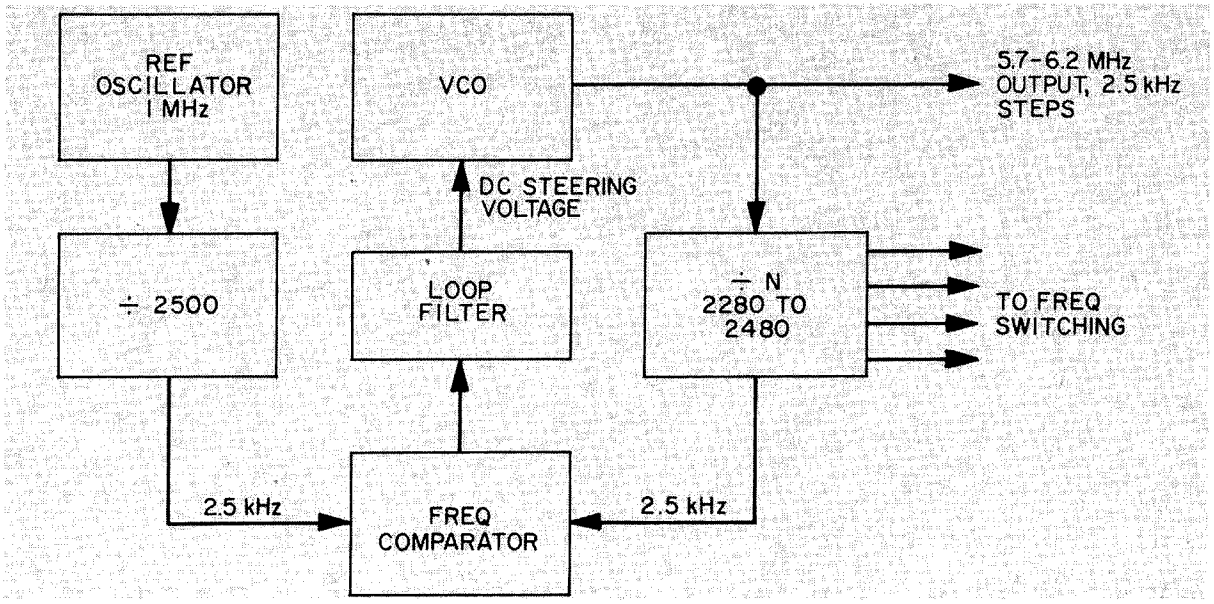

FIG. 3 Block diagram of synthesizer for use in existing transceivers (see also Fig. 1)

The loop filter, necessary in all cases, must remove all traces of the reference frequency at the output of the phase detector (in this case 2.5 kHz). A simple *RC* low-pass filter configuration is usually employed.

The next step in synthesizer development, shown in Fig 4, has a VCO operating in the 135 — 148 MHz range, heterodyned to the 2 — 6 MHz range. This mixing process is necessary because present-day low-cost flip-flops can only divide to about 8 — 10

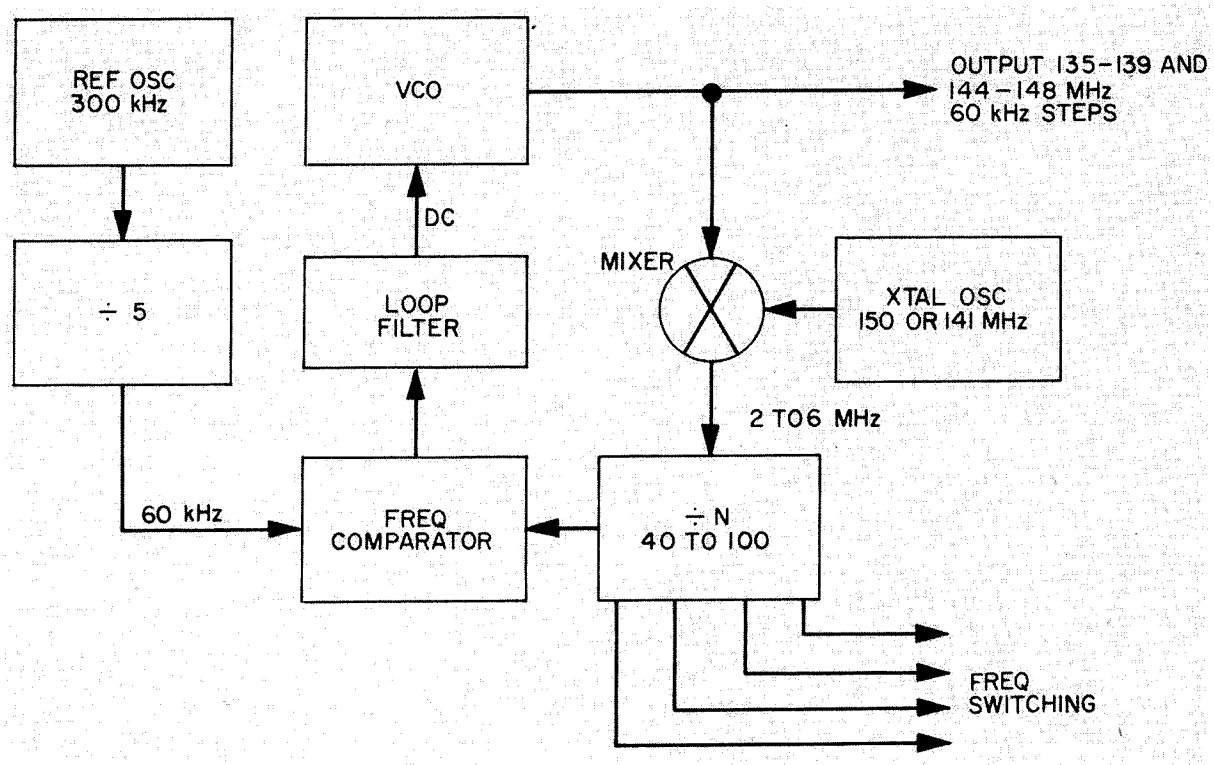

FIG. 4 Block diagram of synthesizer incorporating a mixer and multiplier for generating 60 kHz steps directly in two-meter band

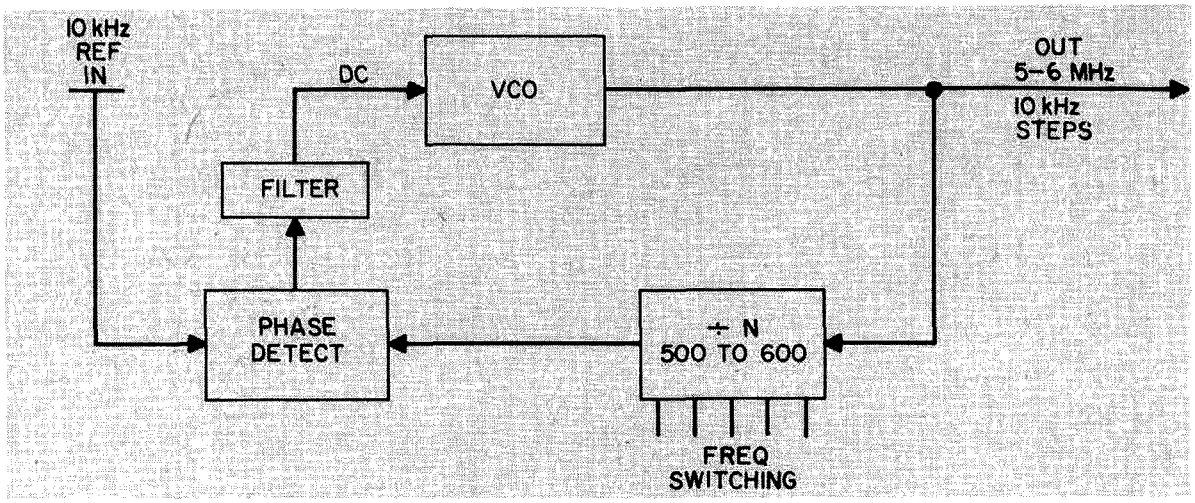

FIG. 5 Simplified synthesizer diagram

MHz in a programed divider circuit. A 60 kHz reference can be used to generate 60 kHz steps because the signal is not multiplied in the receiver and transmitter as in Fig. 3 , thus simplifying both dividers greatly. Frequency stability in Fig. 4 depends mainly upon the accuracy of the 150 and 141 MHz oscillators. Frequency adjustment is necessary in all three oscillators with this scheme. Judicious selection of the frequency spacing, reference oscillator frequency, receiver i-f, and the mixer injection frequencies can result in a design that uses a single crystal.

The Phase-Locked Loop

Indirect frequency synthesizers are basically feedback systems, where phase error is detected and fed back as a correction signal. Such a closed loop is called a phase-locked loop. As a consequence, certain rules must be followed to keep the system stable, as in any feedback system.

The phase-locked loop must have a loop filter at the output of the phase detector to prevent rf from leaking into the VCO control signal (which should be as clean a dc signal as possible). If any rf or ripple appears at this point, it will frequency-modulate the VCO. If the ripple is deliberately applied *as audio*, a desired FM signal can be produced. Undesired high frequency components such as the reference frequency will produce spurious sidebands. Thus, it is the function of the loop filter to remove these undesired products. A second function, however, is to determine the phase — gain characteristics of the loop, which determine its response time, stability, and "capture range."

Capture range is the term applied to the maximum frequency difference the loop will tolerate between the VCO output and the desired output frequency and still *lock up*. Capture range is directly proportional to loop bandwidth. The higher this bandwidth, the higher the adjacent spurious levels — the lower it is, the closer the VCO must be before it will lock up to the desired frequency. A low loop bandwidth also takes longer to lock up. So a compromise is necessary. Despite all of these design criteria, the loop filter is usually a very simple circuit when used in conjunction with a good phase detector.

Phase Detectors

Since the reference frequency of an indirect synthesizer is typically equal to the frequency spacing between channels, the phase detector also operates at this relatively low frequency. The best phase detector circuits are those which deliver the highest ratio of dc to inherent ac ripple. A flip-flop can be used as a digital phase detector, but its output is quite high in ripple content, and it requires a more sophisticated loop filter than other circuits. The

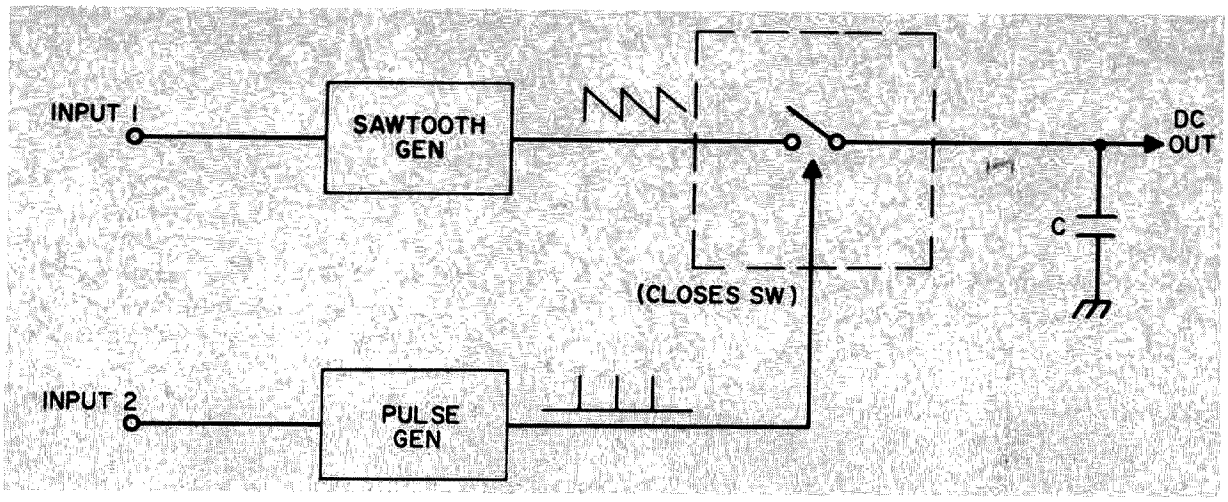

FIG. 6 Sample-and-hold phase detection

best phase detectors in current use work on a *sample and hold* principle. One of the two input signals is converted to a sawtooth, the other to a narrow pulse. The former is called the *ramp*, the latter a *sampling pulse*. As shown in Fig. 6, the sampling pulse operates a series switch for brief intervals so that the value of the ramp voltage at that instant is transferred to a "holding" capacitor. If at the next sampling time there was no change in relative phase between the two signals, the output will not change from the first sample. If there *is* a difference, the output capacitor voltage shifts abruptly up or down to the new value. It can be seen that as long as the two signals are in *phase lock* the output ripple is (ideally) zero. With practical implementation it isn't zero, but it can be made extremely low with careful design.

False Locks

When the phase-locked loop is initially turned on or the frequency is changed, the VCO may be out of the capture range of the loop. Under this condition the synthesizer output is that of the free-running VCO: unstable and at an unknown frequency. The VCO must therefore be tuned to the near vicinity of the desired frequency before the loop will lock up. With most phase detectors a number of *false lock* conditions can occur. A false lock is present when the $\div n$ and the reference frequencies are not equal, but the phase detector "thinks" they are and locks the VCO to the wrong place. A circuit which assures proper acquisitionof the desired frequency is called a "search." It acts as an AFC-type control of the VCO by detecting frequency differences between the $\div n$ output and the reference frequency, rather than phase differences. The search is normally turned off when the phase detector locks the loop. There are a number of ways in which a search can be implemented. Digital methods are compatible with the pulse-type signals available, and they offer simplicity of construction and freedom from adjustment. Best of all, they are nearly foolproof.

$\div n$ Circuits

Except for the advent of low-cost integrated circuits, this part of an indirect synthesizer would probably be impractical to build. It consists of a chain of flip-flops whose function is to divide the VCO signal down to the reference frequency. The number of flip-flops depends upon the maximum divide ratio. Since each flip-flop can divide by a maximum of 2, two can divide by 4, three by 8, etc.; and n flip-flops can divide by 2^n. If the maximum divide ratio is 100, as in Fig. 4, it takes 7 flip-flops, which can divide up to $2^7 = 128$. Six would not be enough because they can divide by only $2^6 = 64$. In Fig. 3, a divide ratio of 2240

is needed; $2^{11} = 2048$, too low; $2^{12} = 4096$. Therefore, 12 flip-flops are needed.

The next problem is to find some way to change the ratio of the $\div n$ by switching so that channels may be selected. Two common methods are used. To understand them, some of the properties of binary dividers must be known. First, the divider can be considered a counter since at each input pulse, or step, the flip-flops take on a unique combination of states. A useful analogy can be drawn to an automobile odometer (mileage indicator), which works in a similar way but counts in decades (powers of ten) instead of binary (powers of two). Including the *tenths* decade, a typical car odometer can count up to 999,999 tenths of miles, and the millionth step brings it back to all zeros. If a switch was provided to close only when all zeros are present, the switch would close once for every 1,000,000 input steps, thus dividing by one million.

One method of changing this ratio would be to reset the odometer to zero whenever it reached the desired count. For example, if a divide-by-567,000 count is desired, it could be accomplished by providing a resetting device which detects the 566,999 state, then resets all decades to zero on receipt of the 567,000th input. By programming the desired state when this occurs, the divide ratio can be any desired number.

Another way is to preset a number into the divider each time it recycles to zero. Achieving a $\div 567{,}000$ with this method requires that a 433,000 be inserted when the counter reaches a natural state of all zeros. The counter then counts from 433,000 to 1,000,000, where it is again preset. This count is 1,000,000 minus 433,000, or 567,000.

Presetting is the preferred method because it is usually easier to implement. Design of high-speed $\div n$ circuits is full of subtleties which make it deceptively easy to design on paper, but another matter to make workable.

Frequency Display

Up to about 12 channels, switching and display of the channel in use is a simple matter. For 30 or more channels it can become a problem, because even if a 30-position switch could be obtained, it would be considerably less convenient to

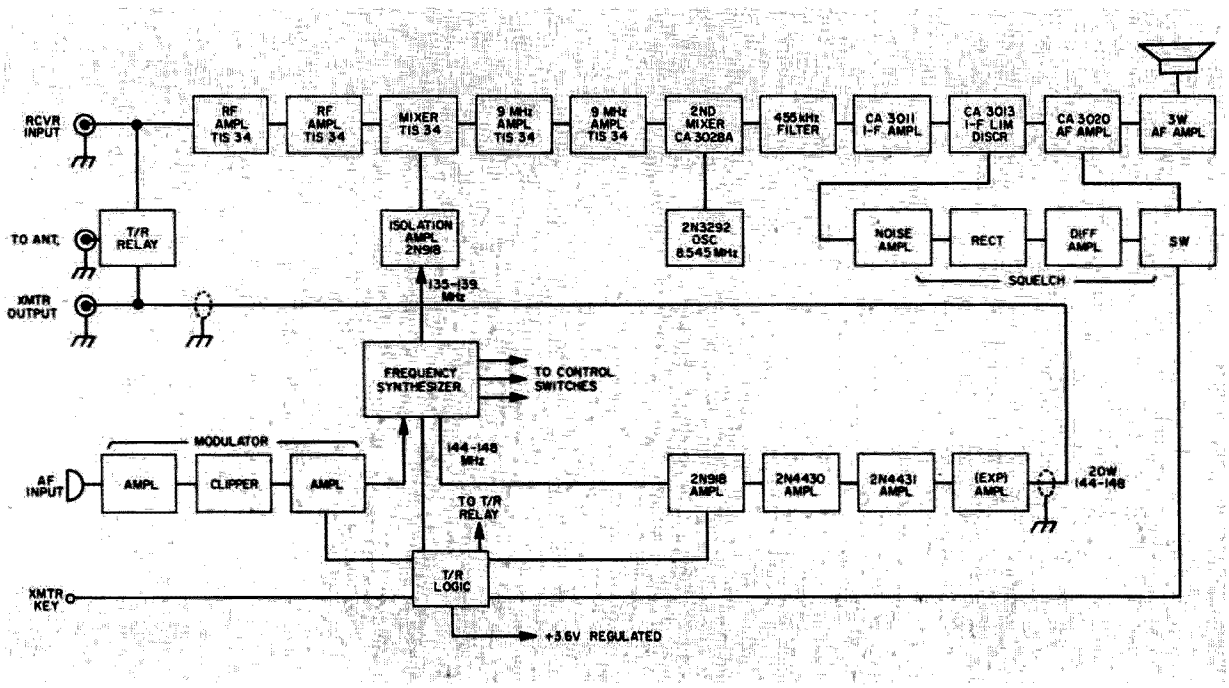

FIG. 7 Block diagram of an FM two-meter transceiver showing how frequency synthesis is incorporated

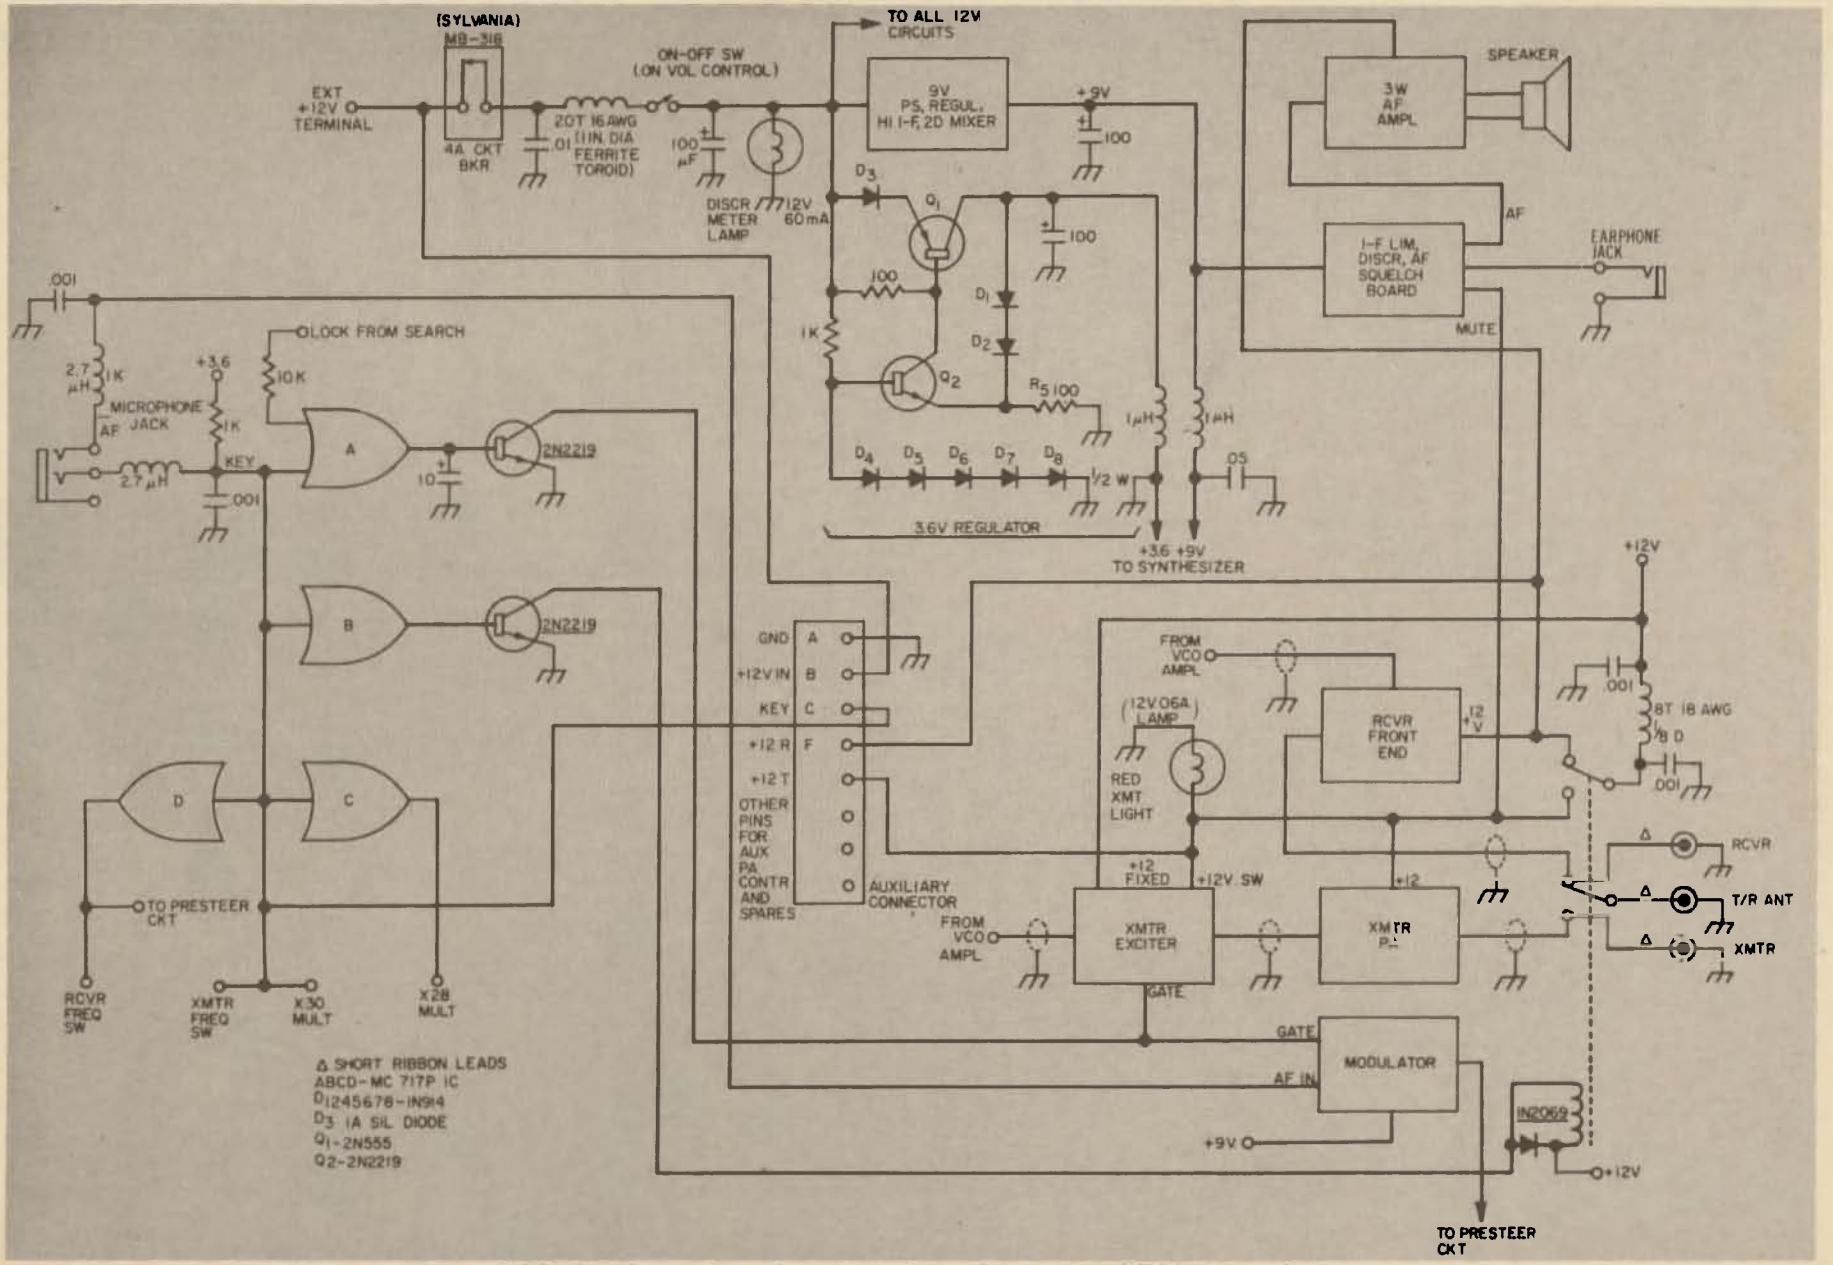

FIG. 8 Transmit and receive wiring for a typical FM transceiver

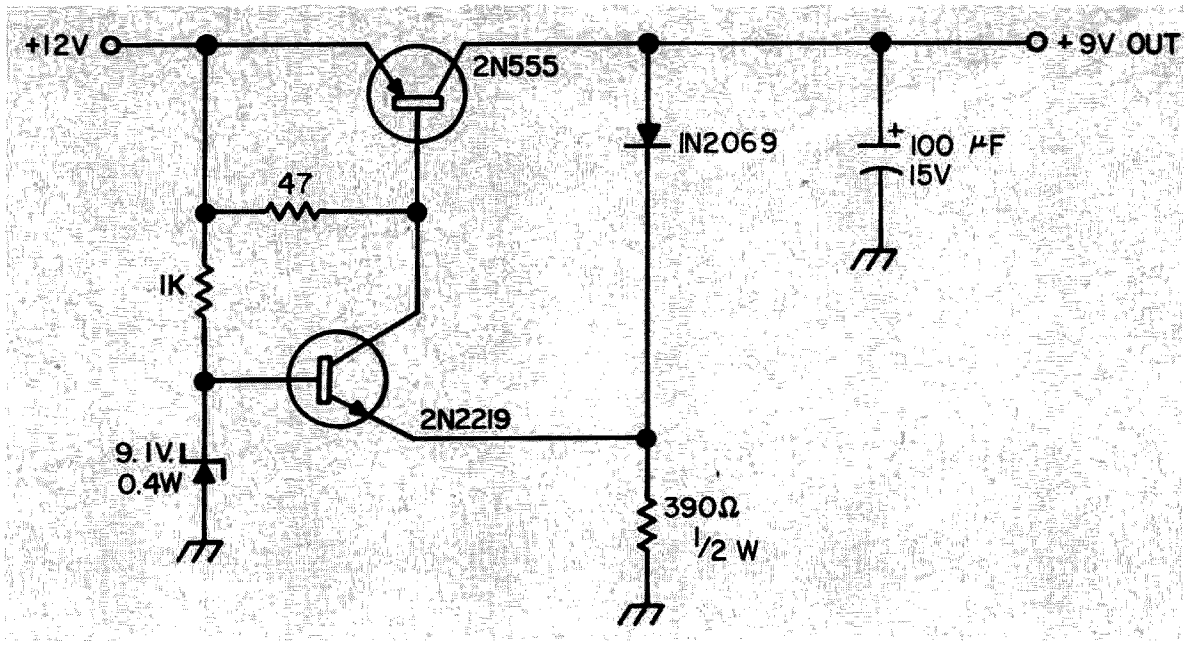

FIG. 9 +9V regulator

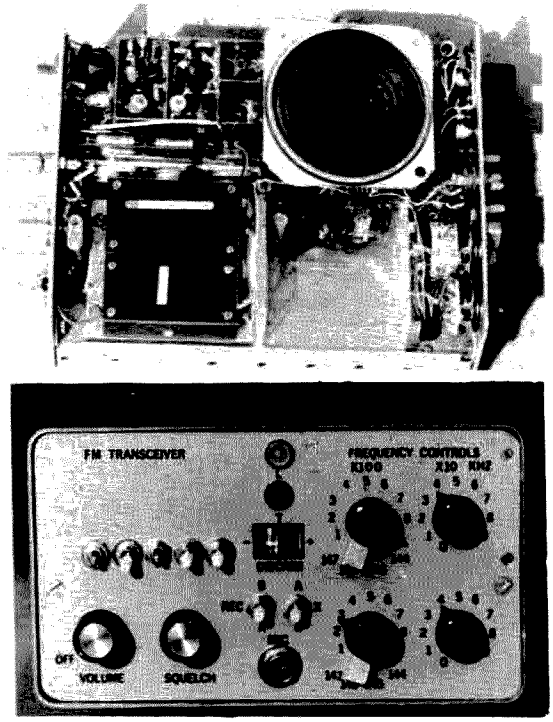
find the channel you want than with only 12 channels.



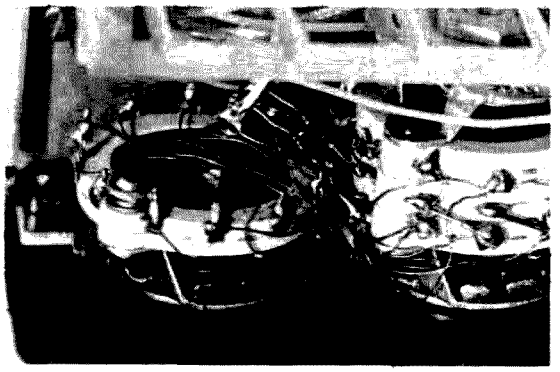
For this reason, switches are usually arranged in a power sequence, such as a *MHz, hundreds of kHz, and tens of kHz* arrangement, extended to as many places as desired. If the $\div n$ were left in its natural state, the switches would have to be set in a binary fashion, which could be awkward. However, the decade type of display is easily accomplished by designing the $\div n$ circuit to work in decades instead of straight binary. It takes 4 flip-flops to produce a $\div 10$ section; cascading three such decades results in a capability of up to 1000 channels. If the channel kilohertz spacing is 1, 10, 100, etc., the frequency display is in familiar decimal numbers. Other schemes can be worked out for different channel spacings, but the decimal method is the most convenient, since most of us think in terms of decimal numbers.

It should be kept in mind that the VCO output is the output of the synthesizer, and even though the loop keeps it exactly on frequency, it can't correct for audiofrequency variations (below the loop filter response). Even if it could, it would be necessary to slow it down for modulation purposes; otherwise the loop would attenuate the audio. Therefore, the VCO of a synthesizer is as sensitive to microphonics as a VFO is, and good VFO construction techniques should be used. VCO tuning range should just overlap each end of the desired output range, and its temperature drift should be kept low to maintain band coverage.

The following text describes the synthesizer used in a 10-kHz-step, 400-channel, 144 — 148 MHz transceiver utilizing a single 5 MHz crystal.

II
A PRACTICAL 10-kHz-STEP SYNTHESIZER FOR TWO METERS

Figure 7 shows the full transceiver block diagram. Output from the synthesizer is 1 mW in the frequency range of 144 — 148 MHz (transmitter), and 1 mW, 135 — 139 MHz, to the receiver first mixer. Modulation is applied directly to the synthesizer for the transmit function. The block labeled *T/R logic* is the circuit board that changes the synthesizer output range when the transmitter is keyed; it also serves to switch the receiver and transmitter and drive the antenna relay.



W2EUP'S homebrew two-meter FM transmitter/receiver looks unbelievably professional. The synthesizer controls are the four at the right of the panel. The top pair sets the receiver frequency, the bottom pair sets the transmitter. The basic frequencies of operation are selected by the integral four-position switches (under the X100 knobs). The frequencies of operation on the pictured unit are 146.34 MHz for the transmitter (national repeater input frequency), and 146.94 MHz for the receiver (national repeater output frequency).

Figure 8 shows the transceiver transmit — receive circuits and the system wiring. Two power supply regulators are used; one generates +9V at 250 mA and the other +3.6V at 1A. Nine volts is the B+ level used in the receiver circuits, the transmitter modulator, and the synthesizer. The schematic for the +9V regulator is shown in Fig. 9.

The +3.6V supply is used to provide power for the digital integrated circuits, which are rated for a temperature range of +15 — +55°C (guaranteed performance). Instead of a zener diode, a series string of silicon diodes is used as a voltage reference for this regulator. This technique produces a temperature-programed supply that delivers over 4V when cold and less than 3.5V when hot. The logic works reliably over a very wide range of temperatures when operated in this manner.

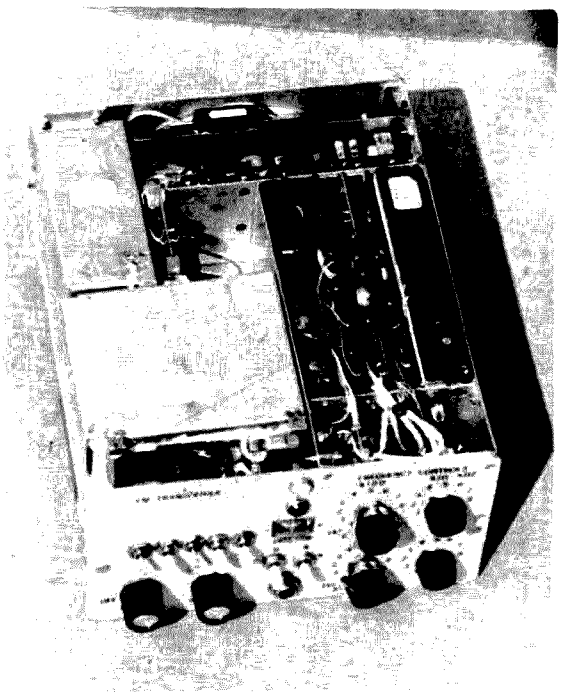
Figure 10 shows the synthesizer block diagram. The single 5 MHz crystal oscillator drives, through an amplifier, a ÷500 fixed divider to obtain the 10 kHz reference frequency, and a dual-frequency multiplier section. When in the receive mode, a multiplication factor of X28 is used, producing a 140 MHz signal. When transmitting, a X30 multiplier supplies a 150 MHz signal to the mixer. The multipliers are selected by the transmit — receive (T/R) logic. When receiving, the VCO output range is 135 — 139 MHz (9 MHz below the corresponding transmit frequency). When mixed with the 140 MHz signal, the mixer output ranges from 5 to 1 MHz (140 − 135 = 5; 140 − 139 = 1) and the ÷*n* divide ratio is preset to divide by any number between 500 and 100, to deliver the 10 kHz output. Since 10 kHz is the reference frequency, the channel spacing is 10 kHz. In the transmit mode the mixer produces from 6 to 2 MHz (150 − 144 = 6; 150 − 148 = 2), and the ÷*n* is preset to any ratio between 600 and 200.

The VCO and VCO amplifier are shown schematically in Fig. 11. The B+ to the VCO should be kept small to maintain maximum tuning range. As it turned out in the unit pictured, tuning range was no problem and had to be reduced by trimming the high end of the range with C6. The VCO is housed in a section of the oven assembly, which also contains the 5 MHz oscillator and an electronic temperature regulator. The VCO itself could have been mounted in a nonheated environment without stability problems because frequency drift with temperature turned out

Detail of frequency selection switches show how "MHz" section connections are skewed 1 MHz offset on receive mode. At right an extra detent (switch clicking and locking mechanism) is reversed and mounted behind. A 1/8-inch shaft is attached and brought to panel through drilled-out shaft of front detent. Rear deck is X100 (hundreds of kilohertz, front two are MHz selection decks. Solderable magnet wire was used for connections to keep the wiring manageable.

to be very low. However, in the author's transceiver, the oven insulation also acts as sound and vibration shielding (polyurethane foam), minimizing VCO microphonics.

Radiofrequency shielding is absolutely essential in the VCO. In the prototype unit, the VCO amplifier was mounted in a separate shielded box, but it was later combined with the VCO itself.



The *steer* input of the VCO comes from the frequency comparator (consisting of the phase detector and search) for electronic lock. An extra varactor (D4) is used to accomplish this by means of a voltage supplied from a presteer circuit (described later) and switched by the T/R circuits.

Three outputs are provided by the VCO amplifier: In addition to the receiver and transmitter outputs, there is a 0.1 mW signal fed to the synthesizer mixer for loop feedback. The resistor network provides some degree of isolation between the outputs. Again, shielding of the VCO amplifier is a must.

Figure 12 shows the frequency multiplier section, the synthesizer mixer and the amplifier used to square up the waveform to feed the $\div n$ circuit. The multipliers are conventional and their outputs are connected in series to feed the mixer. Only one multiplier operates at a time, selected by the T/R circuits. Grounding the X28 or X30 lines selects the desired one.

Mixer output is amplified by several resistance-coupled stages. Transistor Q8 squares the waveform and Q9 acts as an inverter to provide the two out-of-phase signals needed to drive the $\div n$ circuit.

The $\div n$ schematic is shown in Fig. 13. Note that the divider is sectioned into decades I and II and a $\div 8$ section. The terminals shown along the bottom are the

Top view of unit shows circuit board construction and "plug-in" accessibility concept of two-meter FM transmitter/receiver. The two rearmost cards are for receiver. Card next to i-f filter is i-f amplifier. The synthesizer section is shown at right. Left to right, the cards are: phase detect and divide-by-500; search; diode matrices; divide-by-n; mixer-multiplier. The heavy white leads from switches to matrix board are insulating sleeves; each sleeve contains 8 — 12 leads of 32 AWG magnet wire. Slots and holes in shields are similarly guarded with insulation to prevent the possibility of shorts by chafing.

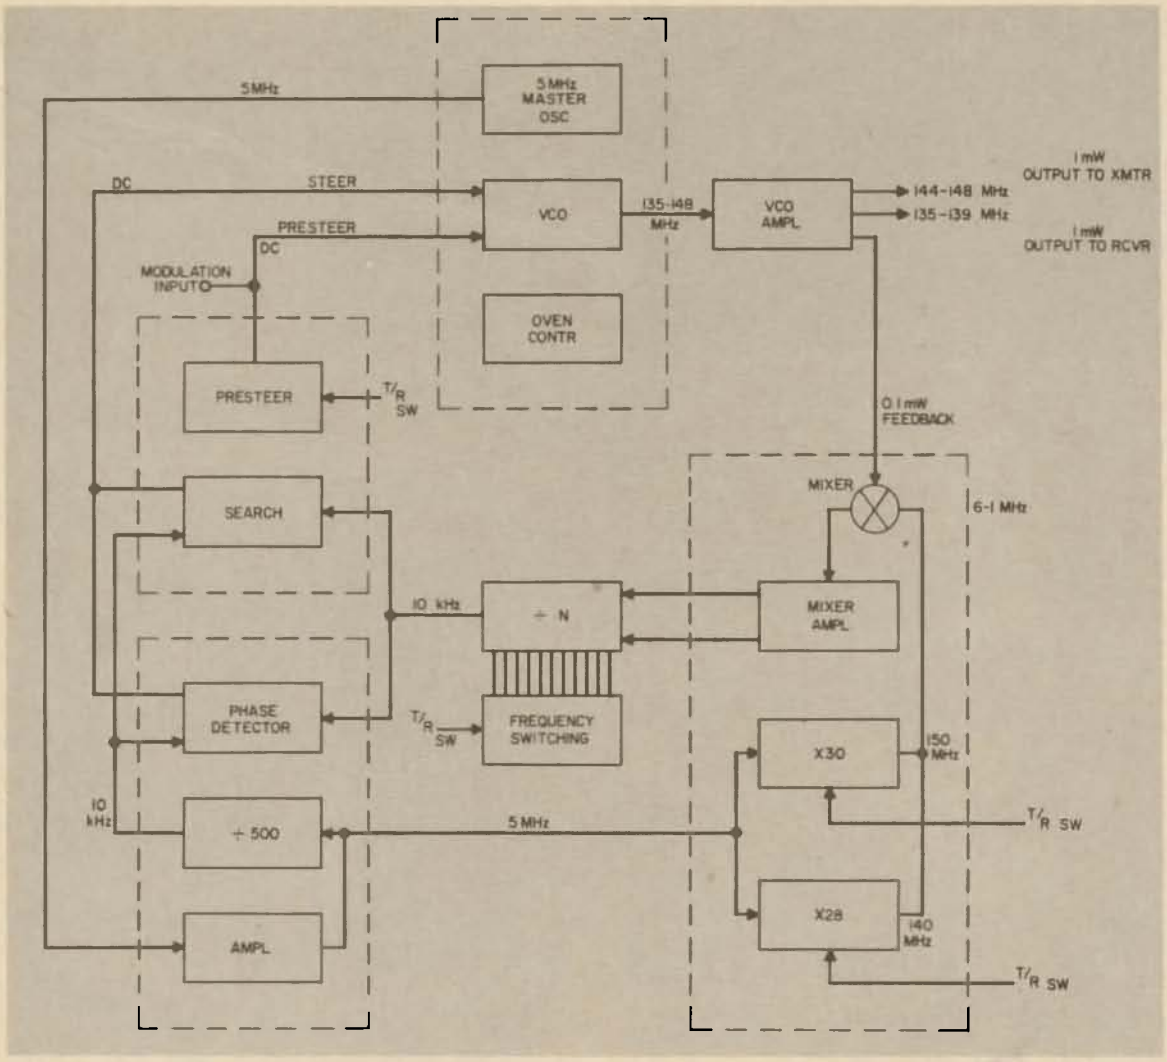


FIG. 10 Detail block diagram of frequency synthesizer

preset inputs. For maximum divide ratio (÷800) all of these terminals are biased to a positive 1 — 4 volts and thus no presets are inserted. Other divide ratios are chosen by selectively grounding (or opening) these terminals. For example, if A1 is grounded, it will divide by 799; if B1 is grounded, it divides by 798; C1 grounded yields ÷796, etc.

A table of presets is given in Table I, showing how the presets affect the divide ratio and the resulting frequencies of operation in this synthesizer. A zero indicates no preset; a "1" indicates a preset on terminals A1 through C3. Under the ÷*n* ratio heading is shown what happens to the normal ÷800 ratio as different combinations of presets are inserted. For example, a preset at A1 only (second line) shows a − 1; this means that the ratio is reduced by a 1 *from 800 to 799. If A_1 and A_2 were both preset*, the ÷*n* ratio is reduced by a 1 and a 10, or 11; therefore, n = 789. Preset lines A1 to D1 thus switch *tens of kilohertz*. lines A2 to D2 go to the *hundreds of kilohertz* switch, and lines A3, B3, and C3 go to the *megahertz* switch.

A 10 MHz shift is accomplished in this design by changing the injection frequency into the synthesizer mixer. Since the receiver oscillator injection requirement is in the 135 — 139 MHz range (to produce a 9 MHz i-f), a 10 MHz shift is necessary to get the output into this range. As previously described, this function is accomplished by the T/R logic selecting the appropriate fre-

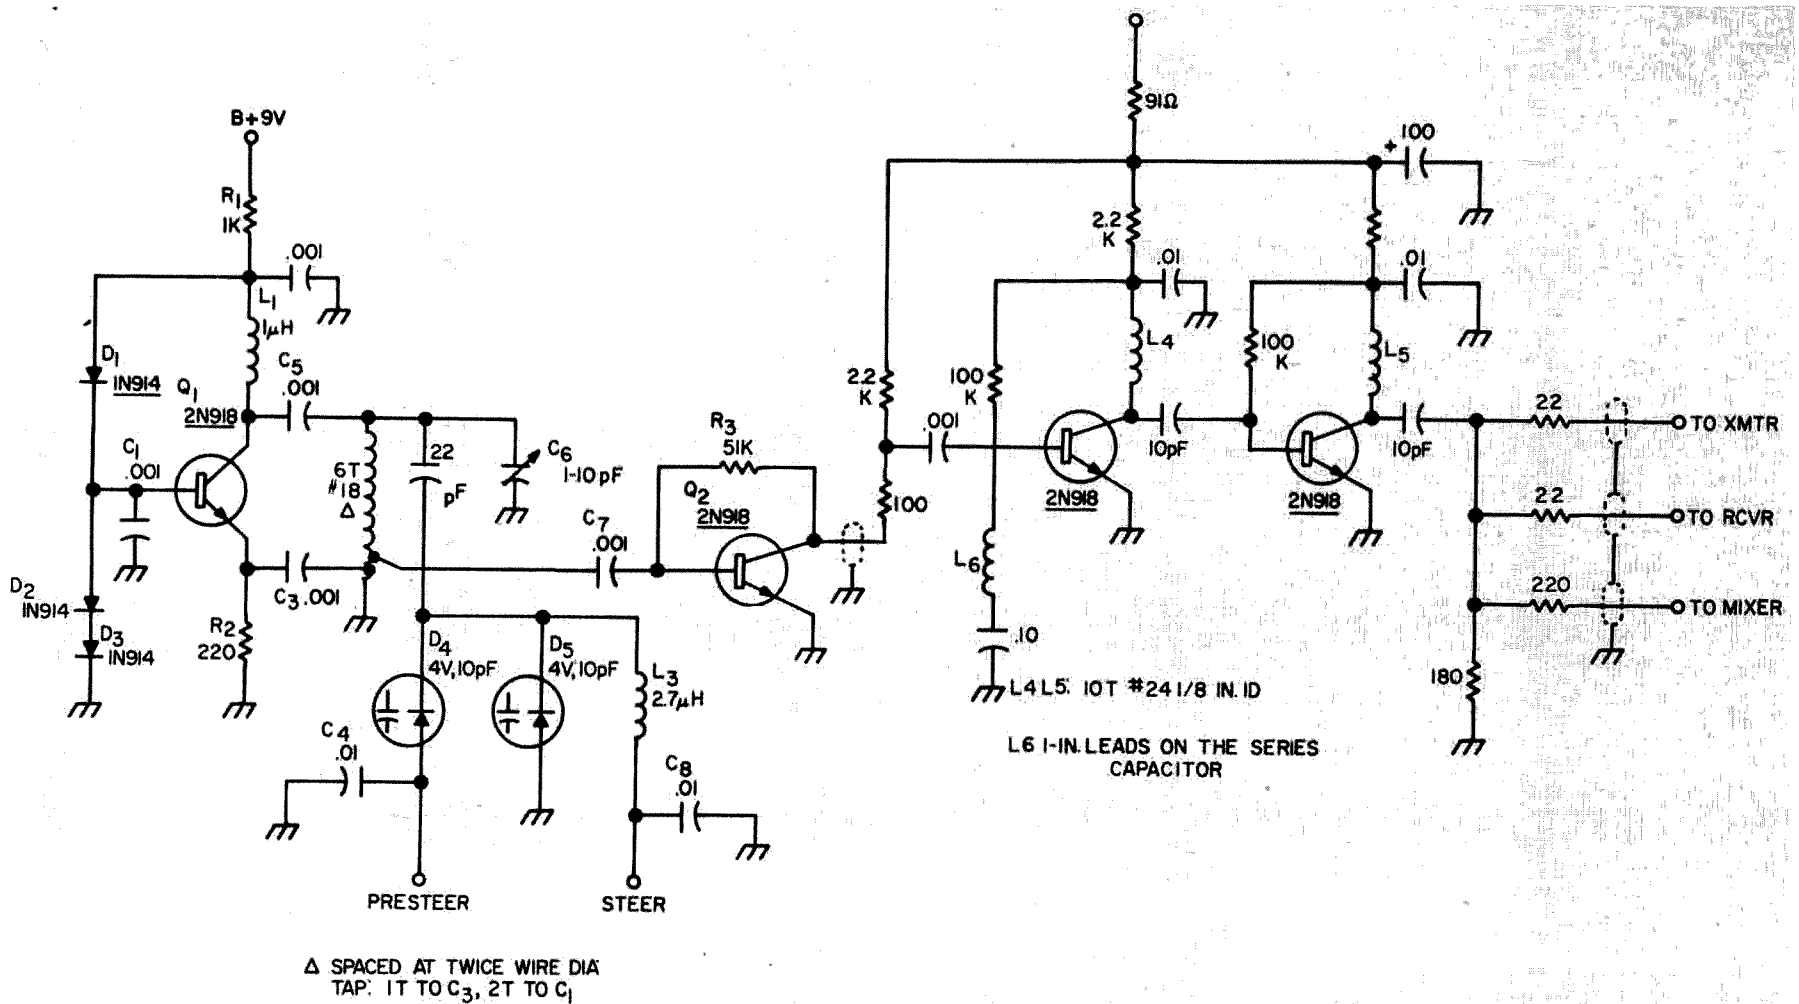

FIG. 11 Voltage-controlled oscillator and associated amplifier

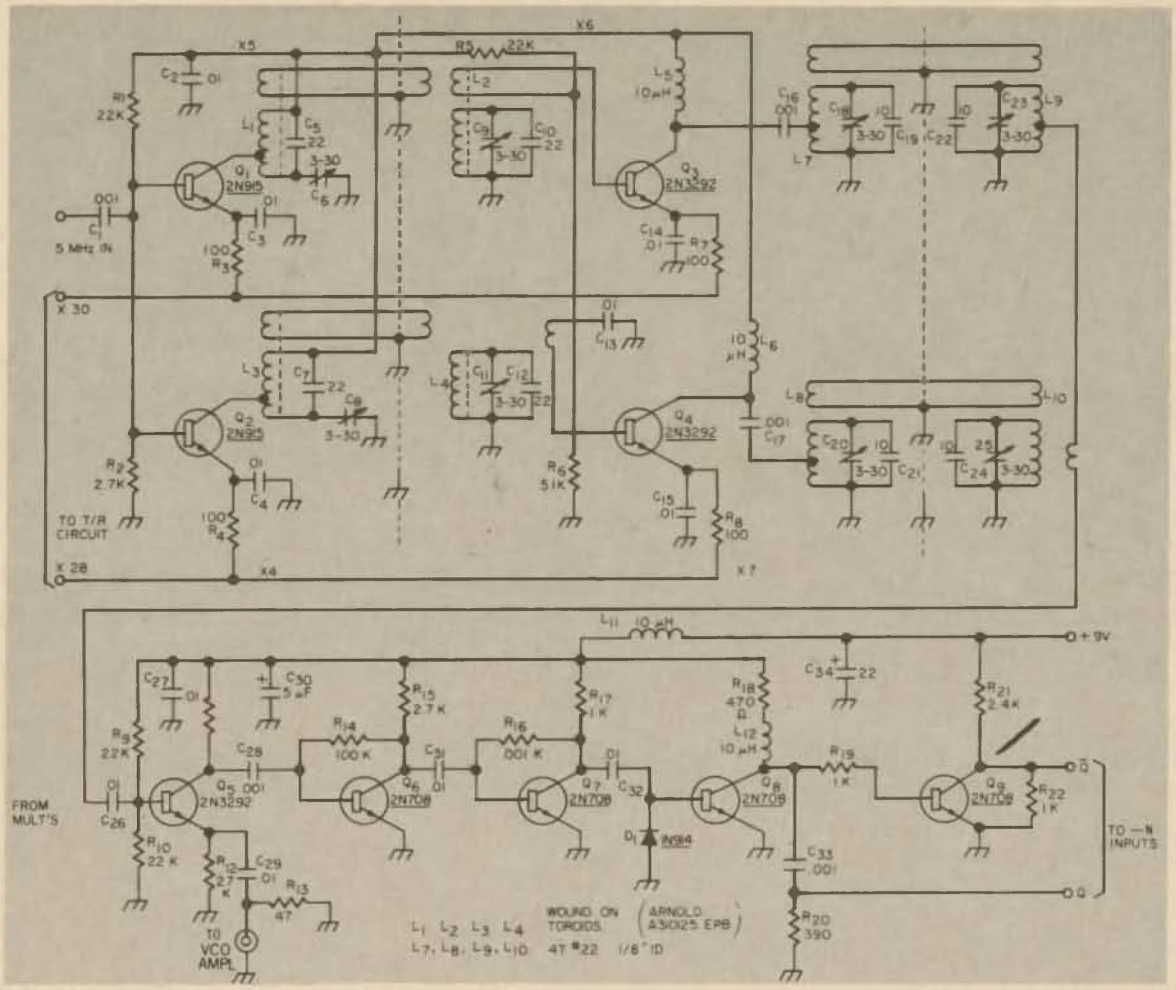

FIG. 12 Multiplier, mixer, squaring amplifier schematic diagram

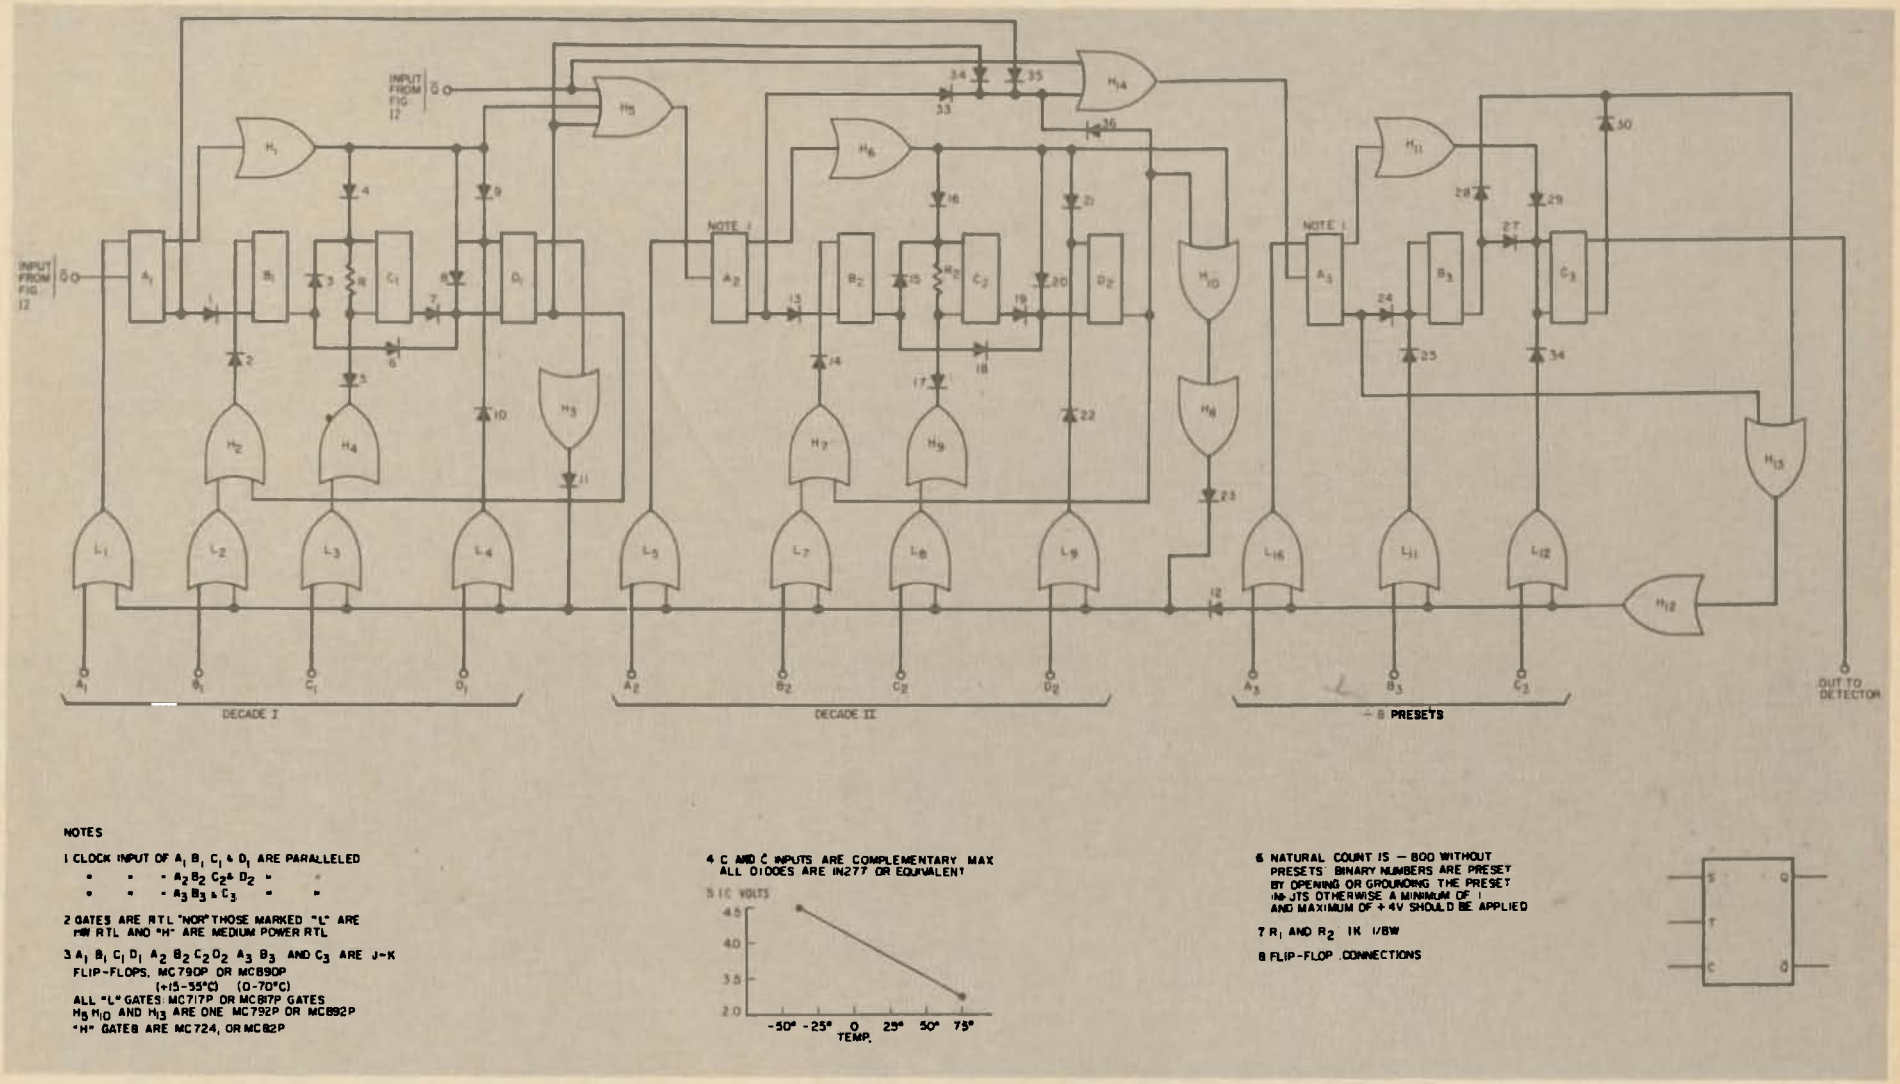
quency multiplier. However, the MHz preset must also be shifted by 1 MHz to receive the same frequency as the transmitter is on, since only a 9 MHz offset is desired. Thus, as seen in the table, the *receive* presets are offset one place in the MHz column.

The $\div n$ circuit shown is capable of operation to 10 MHz for all presets and represents the results of a hard brainstorming session. It should be reproducible and will work as it is shown, as long as the wiring is correct. Unless you understand its theory of operation *completely* it is recommended that you simply copy it *carefully!* Have someone else check *every connection* since troubleshooting is difficult. Space doesn't allow a complete explanation of its operation.

Frequency switching circuitry is shown in Fig. 14. Two complete sets of switches allow independent selection of receive and transmit frequencies. The diode matrices shown permit the use of standard 10-position rotary switches. Input voltage for the preset lines is provided through the 10K resistors. When one of the lines is grounded, a combination of presets is grounded through the diodes.

The arm of S1 is grounded in the transmit mode, and the arm of S2 is grounded in the receive mode. If S1 is in the *A* position, the transmit frequency is controlled by switch set *A*; if it is in the *B* position it transmits on the frequency on set *B*. The same is true for S2 on receive.



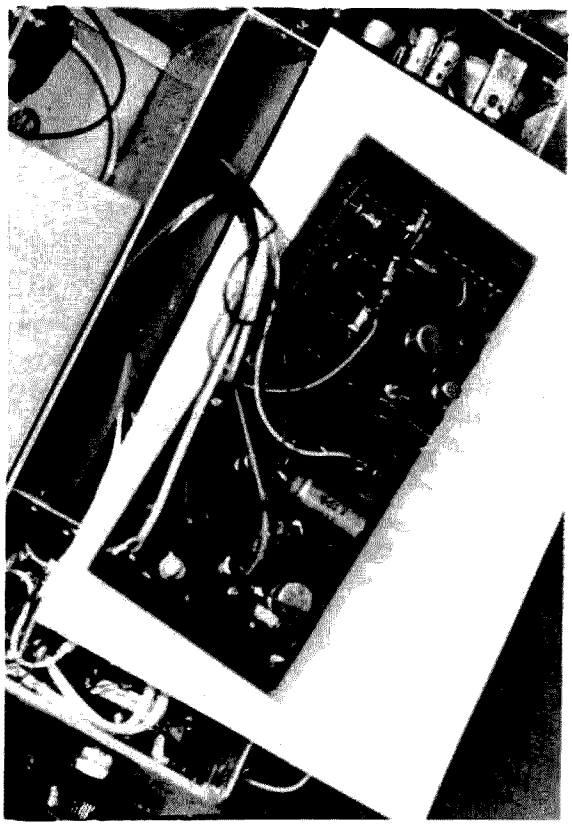


FIG. 13

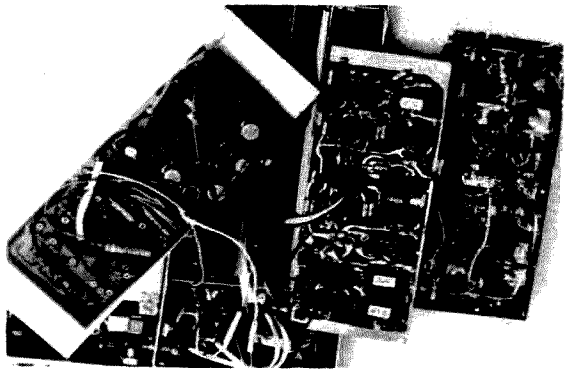
÷*n* CIRCUIT



Closeup photo shows that it is practicable to get all the components of the phase detect and divide-by-500 circuit onto a single small card.

These switches provide great flexibility. With both switches in the *A* position, you transceive on frequency *A*. Similarly, with both in the *B* position you transceive on frequency *B*. Receive A and transmit *B*, receive *B* and transmit *A* are other combinations. It may sound complicated, but this system is very easy to use and a beginner can master it in seconds.

Once understanding of the method of controlling the synthesizer is complete, you can dream up all kinds of ways to control it. For example, it is simple to instantly select a preset channel, such as 146.94 (the national FM repeater output frequency) by throwing a toggle switch. This addition can be completely independent of other switch positions. And remote switching is easy because all control lines to the $\div n$ circuit handle only dc and simply are grounded in different combinations.

Figure 15a shows the master oscillator. It uses a field-effect transistor and has an automatic gain control arrangement for high stability. It is completely shielded and oven-controlled (Fig. 15b.). Asterisked components are thermally mounted to the oven box; the thermistor senses the oven temperature, and the other asterisked components deliver heat to it. In the original unit, the temperature control pot is mounted outside of the oven.

Referring to Fig. 15c, the 5 MHz low-level signal from the master oscillator is amplified in Q1 and Q2. Output from Q2 goes to the multiplier section and to squaring amplifier Q3, which drives the $\div 500$ circuit. Two outputs are used from the last flip-flop (I) 180 degrees out of phase. One goes to the search circuit, the other to the phase detector, below. The 10 kHz square wave is converted to a *spike* by C6—R9, as seen in waveforms *a* and *b* in Table II. Each positive spike turns Q5 on momentarily, charging C7 to +9V. Between spikes (waveform *c*), C7 discharges through R15, producing a sawtooth. (A linear sawtooth could be used instead of the nonlinear one used here, but the nonlinear waveform is actually beneficial in this system and is easier to generate.

Closeup photo shows the search board at left, the divide-by-n card and, at right, the mixer — multiplier assembly. The wall shield between those boards still in place are made from a conducting material deposited onto the fibrous board material; the close spacing increases the possibility of card-to-wall shorting, so a Mylar insulation sheet was attached over the surface of each of the shield walls.

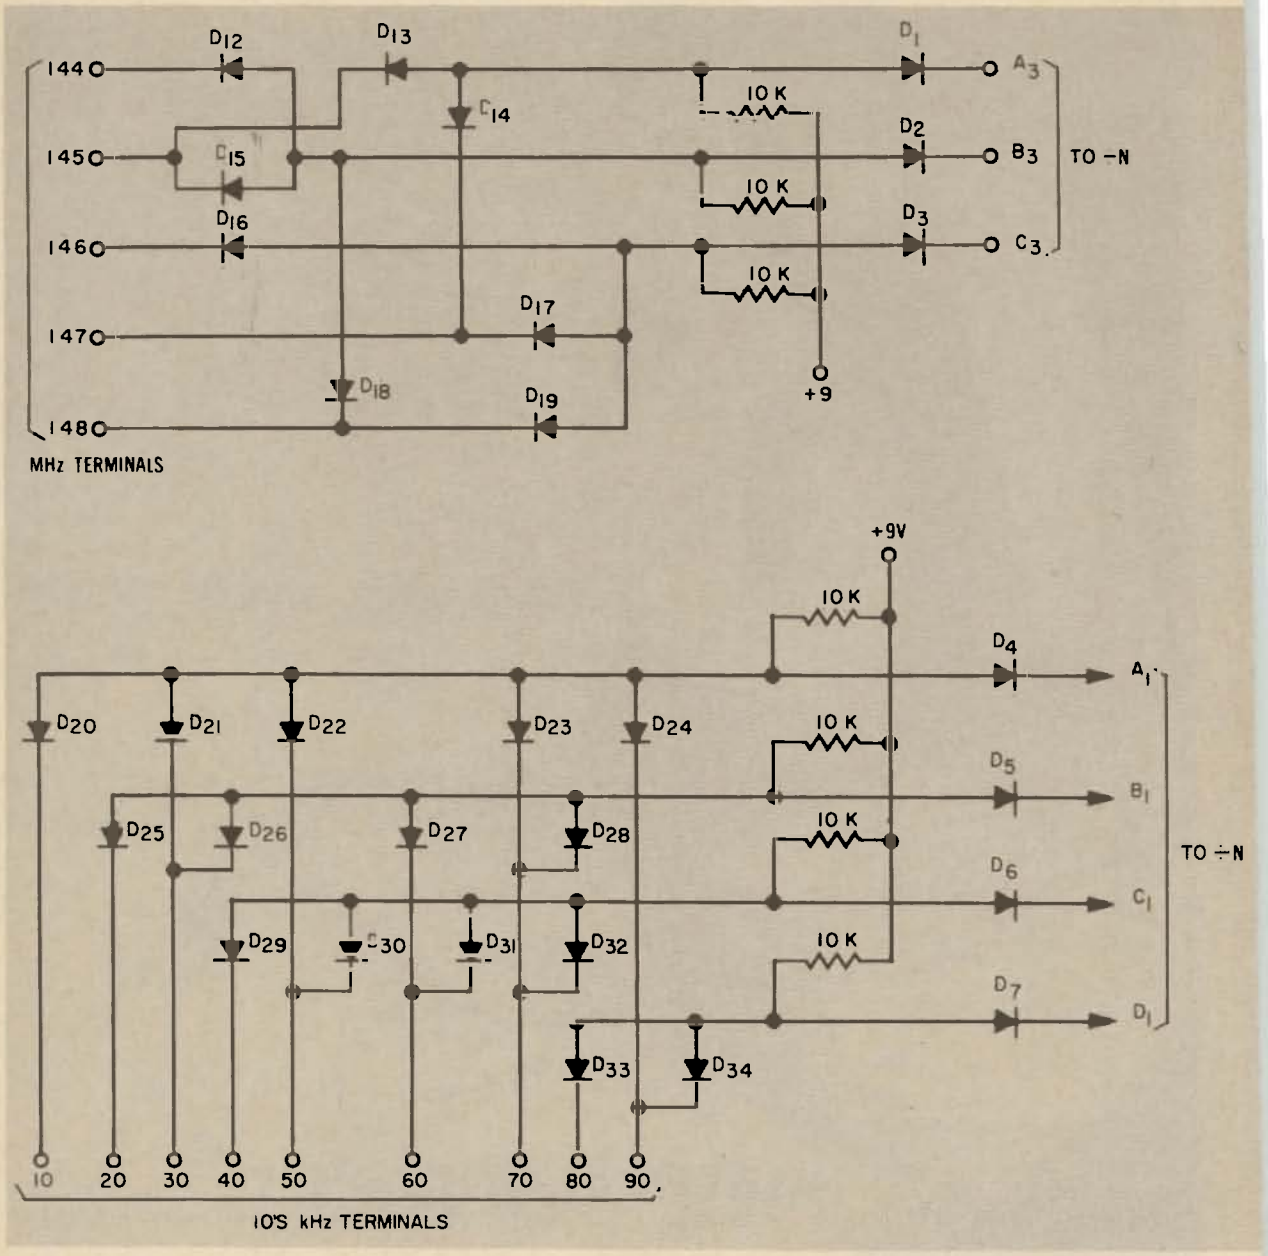
Sampling pulses are produced from the ÷*n* output in a blocking oscillator (Q3) and fed to the gate of Q6 (waveform *d*). This pulse turns Q6 on briefly, charging or discharging C9 to the value of voltage on C7 at that instant. Capacitor C9 can only charge or discharge through Q6, so it holds that value of voltage until the next sampling pulse. Different ÷*n* outputs and the resulting voltages across C9 are shown in Fig. 18, *d* through *i*. Transistor Q7 is a source follower which drives the following circuitry at a low-impedance level, while maintaining a near-infinite load on C 9. The loop filter consists of R13, C10, R14, R16, diodes D5 and D6, and the rf bypasses at the VCO. The diodes effectively short out R16 for sudden large shifts in phase-detector output to speed the lockup process. For small changes, as seen when the loop is in lock, they have no effect.

A bias voltage is developed from the high-amplitude blocking oscillator output with D3 and D4. This bias is used to hold Q6 off between sampling pulses and to bias the varactor presteer input on the VCO.

Figure 16 shows the search circuit. It operates from the same two frequency inputs that the phase detector uses, except that its purpose is to detect *frequency* in-



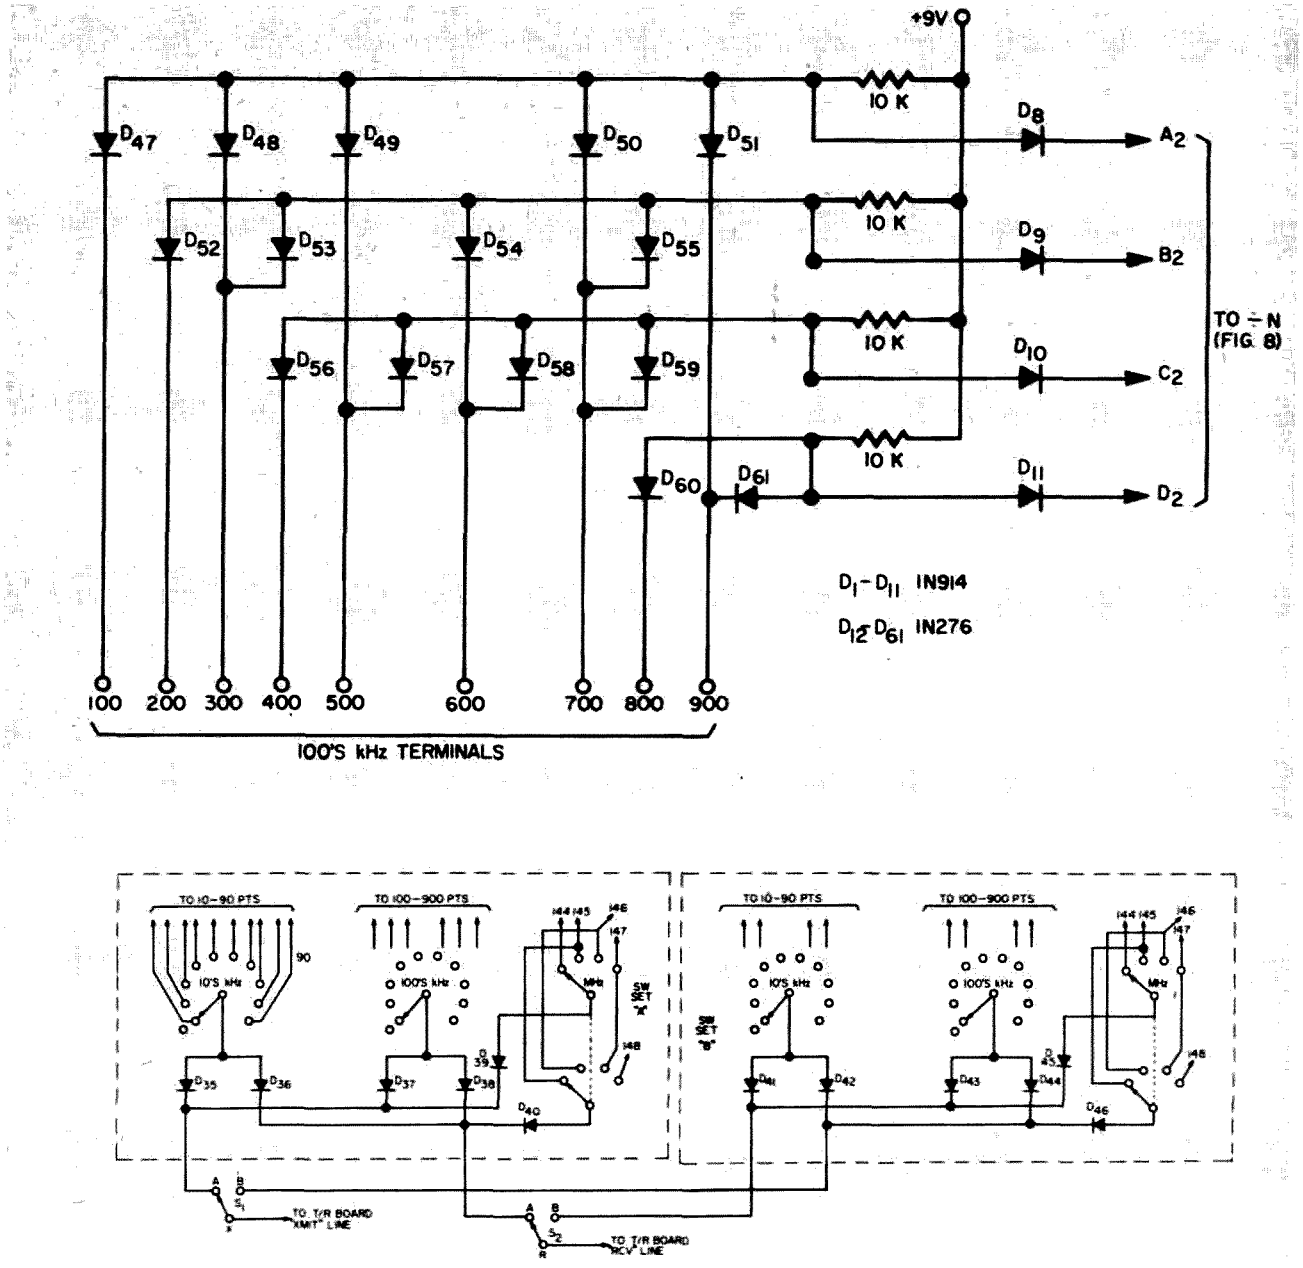


FIG. 14 *Frequency-switching with*

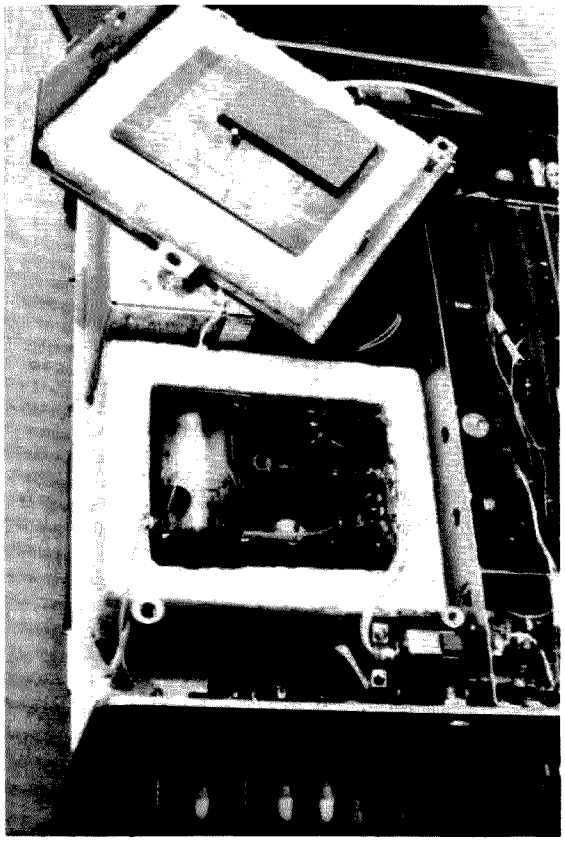
stead of *phase differences*, and to coarse-tune the VCO to the desired frequency, where the phase detector takes over. It accomplishes this by checking for pulse interlace; that is, to see that for every pulse received on one input there is *only one* pulse received at the other input. Obviously, if two pulses occur from one input during which time no pulse from the other input is received, the two pulse trains can't be of the same frequency.

Table III shows waveforms for the locked condition (*a*, *b*, *c*) where the comparator, consisting of gates BCGEHF, etc., does not produce any output pulses; and where the $\div n$ output is too high in fre-

diode matrices for rotary-switch utilization



quency (*d*, *e*, *f*). When this case exists, gate H delivers pulses. When the $\div n$ output is too low in frequency, gate F puts out a series of pulses. When pulses come from H, Q6 and Q3 are pulsed on, producing a stepwise increase in voltage across C9. This voltage is summed with the voltage from the phase detector. As it rises, the VCO is tuned higher in frequency, which decreases the output frequency from the synthesizer mixer, decreasing the $\div n$ output frequency as desired. A correction in the opposite direction is accomplished by pulsing Q4 from gate F, decreasing the C9 charge in steps.

Gates I, J, and D do two things: they gate the transmitter off while the loop is searching (so you don't search while on the air) and they drive the out-of-lock indicator light (which tells you when something is wrong). The indicator normally flashes briefly between receive and transmit If anything goes wrong in the synthesizer the light is almost sure to indicate it.

Transistor Q8 is used as a presteering gate. Controlled by the T/R circuit, it is biased on in the receive mode, placing a positive voltage on the presteer input of the VCO. This voltage, adjusted by R16, reduces the voltage across varactor D4, increasing its capacitance and shifting the VCO tuning range down. When Q8 is off (in the transmit mode) the bias is allowed to swing to −10 volts, which reduces the capacitance of D4 to a minimum. Diode D9 regulates this bias level. Modulation is ac-coupled to the presteer input instead of the steer input so that it does not interfere with the operation of the loop. The 220 pF capacitor is an rf bypass. Modulation input impedance is 330K, and very little voltage swing is needed for 15 kHz deviation. Linearity for this level of deviation is excellent and hi-fi audio is possible.

Transistor Q2 is used to prevent a possible hangup condition of the loop, where the VCO gets tuned so low that the frequency supplied to the $\div n$ is beyond its counting capability. The $\div n$ would then start counting erratically, delivering too few pulses instead of too many, due to skipping pulses. The search circuit interprets this to mean that the $\div n$ output is too low instead of too high, so it steers the VCO in the wrong direction, perpetuating the situation. Luckily, the bias supply in the phase detector happens to depend upon a continuous supply of $\div n$ pulses, so that when this hangup condition occurs, it can be detected by a large drop in bias voltage. Transistor Q2 is normally biased off by this supply, but when the loop hangs up, bias collapses, so Q2 turns on and turns search transistor Q3 on in good *Rube Goldberg* fashion. Transistor Q3 charges C9 to maximum voltage, sweeping the VCO to the high end of its range, where normal lockup can take place. The entire process takes place in a few milliseconds. C3 causes a delay to make sure that Q3 turns on completely.

The oven assembly should be thermally isolated to the greatest extent possible. In the unit pictured, the crystal oven circuit is isolated from the remainder of the circuitry by means of a thick styrofoam surround. Shown in the oven are: the crystal (at left), voltage-controlled oscillator (in corner compartment), and 5 MHz oscillator with oven control circuit.

Shielding

Most of the circuits are susceptible to the high-level rf fields typically generated by an adjacent transmitter. The $\div n$ circuit is an efficient hash generator to nearby receivers at nearly any frequency. It is therefore important that most of the synthesizer circuits be shielded from the outside world as well as from each other. All leads should be filtered and bypassed with *RC* or *LC* circuits. Extra B+ bypasses in

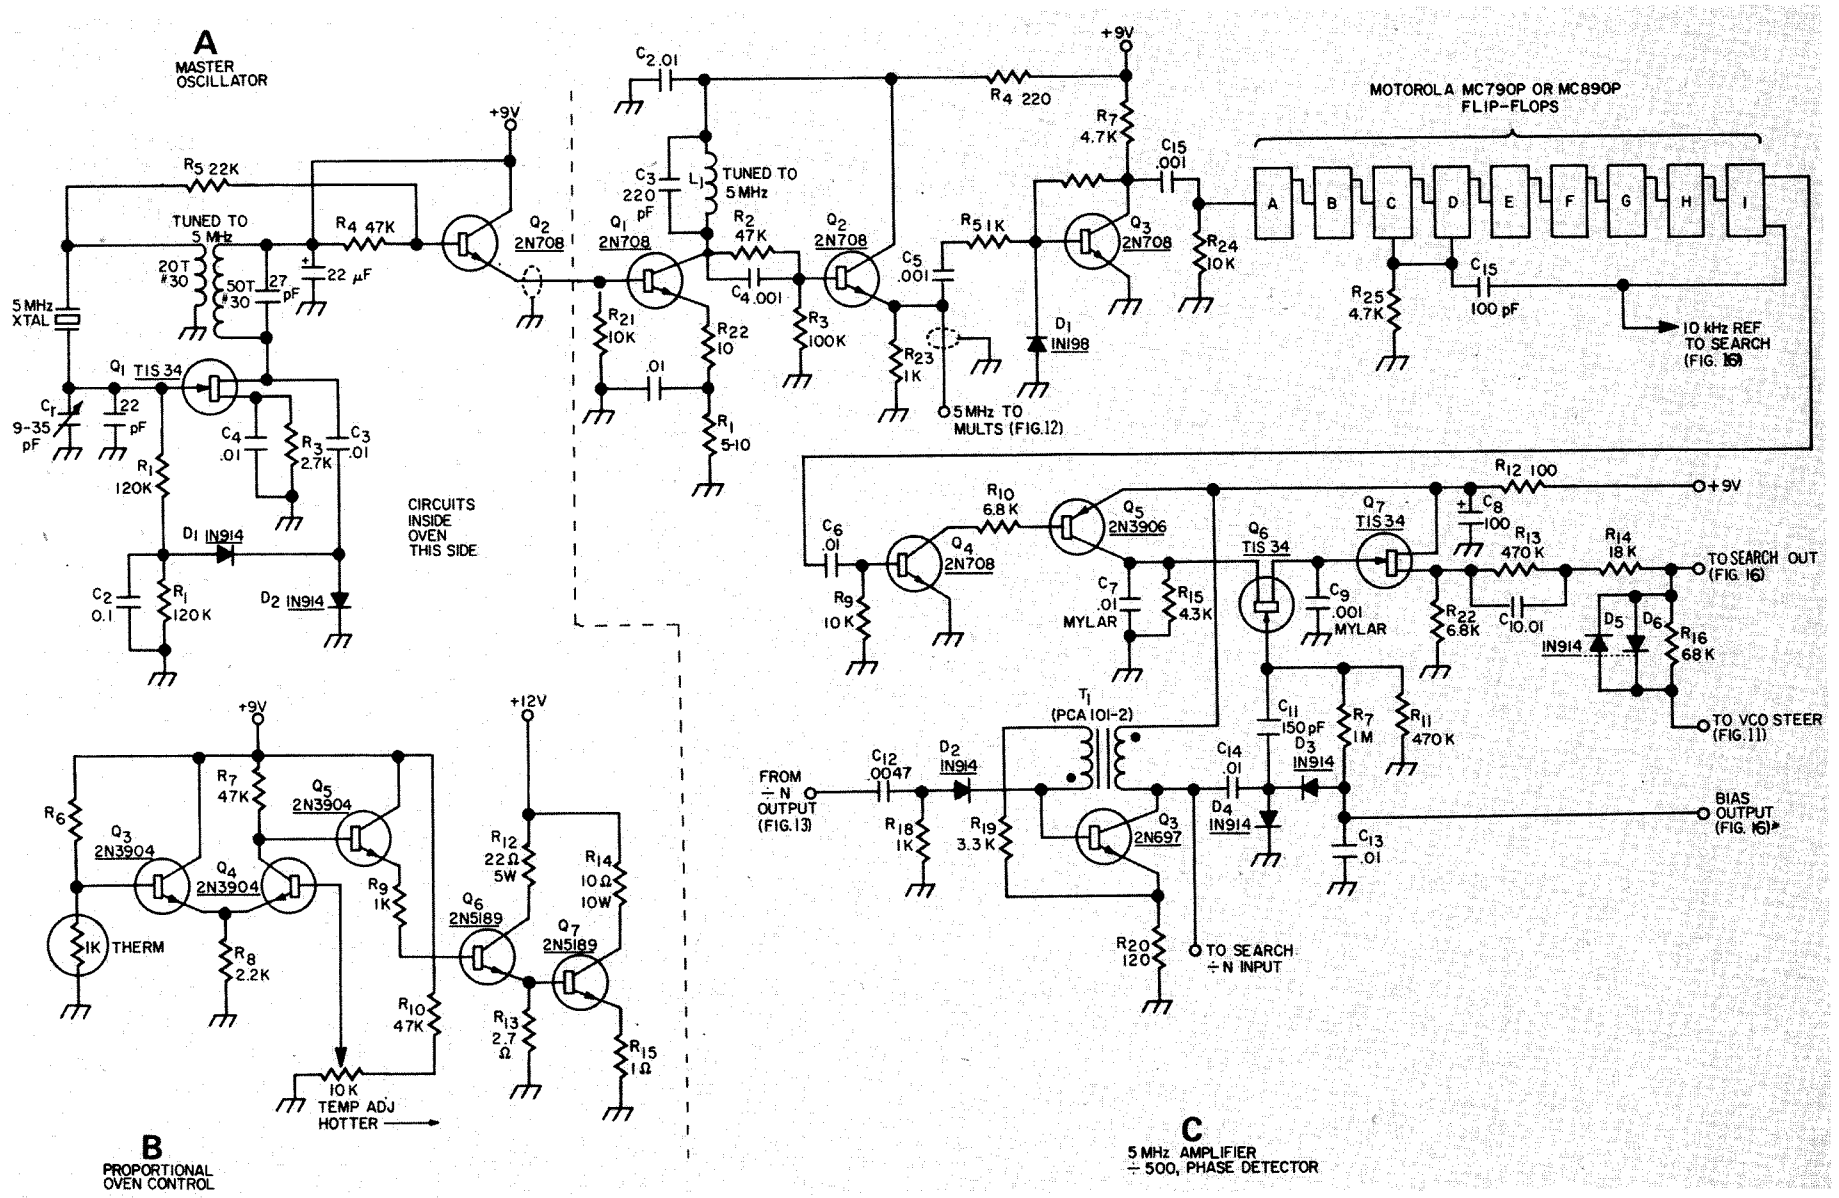


Fig. 15. Oscillator, 5 MHz amplifier, and oven control

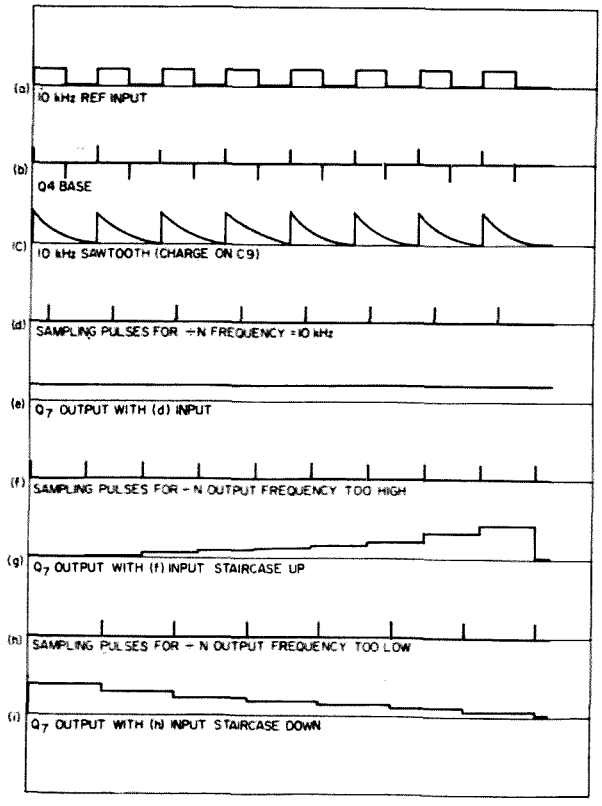
Table II. Phase detector waveforms.



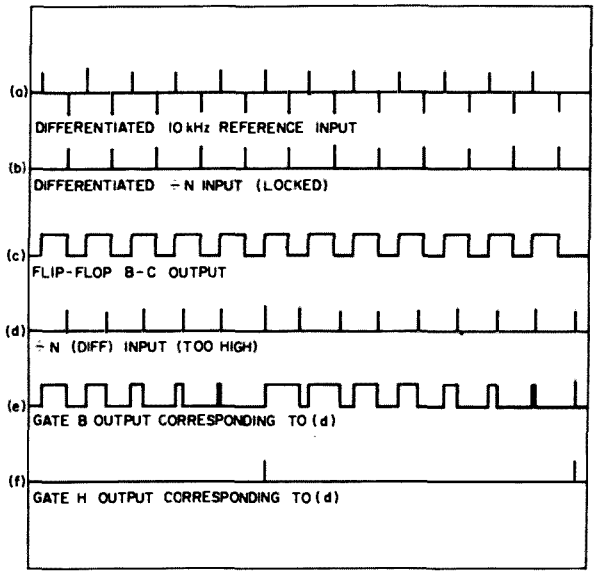


Table III. Search waveforms.

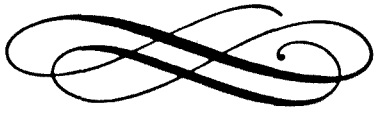
the system will be found helpful in various spots. The most insidious form of system trouble is when complex circuits interact in ways not anticipated; so make sure the circuits function as they should separately, and then combine them in sections. Test everything for proper function before making any attempt to close the loop. When the loop is out of lock, everything jumps at once, and it is truly enough to make a grown man cry. Usually, the only hope is to open the loop and check individual circuits. With experience you can read the signs and troubleshooting becomes just as easy as robbing Fort Knox.

Performance



With a good master oscillator you can get counterlike frequency accuracy on all channels. The author's unit is accurate to better than plus or minus 20 Hz at two meters with a 20 minute warmup. Even without a warmup period, it is considerably better than most crystal-controlled rigs after stabilization.

Unlimited channel flexibility is a recurring pleasure that intensifies with time. Anyone who tells you that you are off frequency has just *got* to be from out of town! Even if you have a doubt, it takes only one quick zero-beating check against WWV to *guarantee* superaccuracy on all channels!

The big worry most people have about synthesizing frequencies is the potential spurious outputs. The author's unit was cheked on an H-P spectrum analyzer from 10 MHz to 2,000 GHz and found to be clean to –70 dB from carrier, excepting harmonics. And even at that level there was only a 5 MHz sideband pair, originating from the master oscillator. Adjacent 10 kHz sidebands couldn't be measured directly, but calculations based on the ripple level measured in the VCO feedback loop indicate them to be over 65 dB down. This figure is consistent with on-the-air observations.

It *is* worth the trouble. You must use a synthesized rig to appreciate it!

in FM REPEATERS

COMPLETE IN THIS ISSUE

Editor's Introduction;

An interesting and unforeseen problem developed as a result of the tremendous growth in popularity of FM repeaters: When two or more repeaters operate with overlapping coverage on the same input or output frequency, mobile operators occasionally find themselves triggering more than one repeater. The mobile operator who does so may thus cause interference by his unintentional keying of the repeater in a neighboring community.

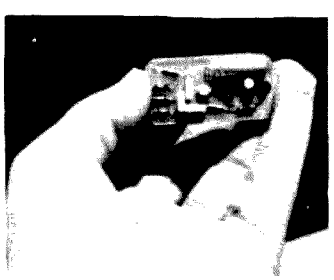
As a rule, shifting the frequencies of one of the repeaters is no solution, because both relay stations will want to be on the nationally accepted standard (146.34 MHz input, 146.94 MHz output). Such standardization is a boon to the mobileer who has a limited supply of crystals and must travel across the country or from one area to another once in a while.

But there are workable solutions. More and more, repeaters in highly congested areas are going to a "tone-burst entry" approach or a "whistle-on" system of keying. With a whistle-on system, the control circuits are all at the repeater site. The repeater is never operative unless specifically activated by one of the users.

A broad whistle on the input frequency energizes a decoder at the repeater site, which in turn activates the automatic signal-relaying system. Typically, the repeater stays on, once activated, retransmitting the signals of all carriers on the input. When the traffic dies down a bit—that is, after a short period of no signals—the repeater shuts down again, and cannot be used unless someone deliberately calls for it by whistling on the input.

When multiple-repeater conditions are more severe, the tone-burst keying system is the more satisfactory solution. Here, a specific tone frequency—usually 1700 to 2000 Hz—must be present briefly at the outset of every transmission before a signal can be automatically relayed. In practice, all who intend to use the repeater will install simple audio oscillators into their transmitters, connecting them in such a way that the tone comes on briefly each time the transmitter is keyed. The tone, decoded at the receiver of the relay station, is used to activate the repeater— but only for the duration of a single carrier.

The first article in this series of three describes how whistle-on and tone-burst repeater systems are used and presents schematics of a simple oscillator suitable for use in whistle-on systems as well as a "microencoder" that can be adapted to either tone-burst entry or subaudible continuous-tone squelch systems. The second article in the series gives construction and theoretical details for a decoder ideal for use with either of the two single-tone oscillators of Part I. The third article, by Les Cobb, describes a network of tone-burst repeaters, and includes information on how to set up a tone-burst oscillator in a mobile transmitter and how to connect a decoder into a repeater system. Together, these three articles provide complete information for converting an existing repeater facility to tone access.



Part I: *by John Gallegos W6ZCL*

Encoders for Subaudible, Tone-Burst, or Whistle-On Use

The FCC sanctions the use of semicontrol techniques such as continuous-tone carrier squelch systems (very low frequency tones accompanying all carriers) and single-tone (tone-burst entry or whistle-on access) in applications where limited access to a remote station or a repeater is desirable. The W6FNO repeater in Southern California went one step further, and the result is a repeater that is fully compatible with two-way nonrepeater operation taking place on the input channel.

In many ways, the W6FNO repeater at Radio Ranch could serve as a model installation: The repeater stands ready for use 24 hours a day and is never shut down where it cannot be accessed by a station on the input frequency. On the other hand, the repeater will shut itself off if a three-minute period elapses with no signals on the input. Sounds a little contradictory, but it isn't—not really. The W6FNO repeater was an experiment to test the concept of subcontrol, i.e., limited control of the repeater from the actual frequency of operation.

The repeater is equipped with two timers. The first timer is a transmission-limiting device: when the input carrier exceeds three minutes duration, B+ is removed from the transmitter final; and it can only be reapplied after the input carrier drops out momentarily. The second timer removes the transmitter B+ also. But in this case, the timer is activated by the absence of an input signal. Since the shutdown is only B+ removal, the repeater is ready to be activated immediately upon application of the proper signal, which in this case is nothing more than a shrill whistle.

Barely more than a thumb's width, the W6ZCL phase-shift oscillator is small enough to be packaged within the case of almost any commercially available hand-held transceiver.

The W6FNO repeater is a "talkback" type, as opposed to a "prime" repeater. A talkback repeater uses a national FM channel as the input frequency and a nonactive channel as the output. A prime repeater uses a nonactive channel as the input and an active, popular frequency as the output. The popular 146.34-to-146.94 repeaters across the country are primes. If the frequencies were reversed, they would be talkbacks.

The active FM channel for direct nonrepeater operation in the W6FNO territory is 146.82 MHz, which also serves as the repeater input. The repeater output frequency is not used at all except by stations who want to hear what's going through the repeater. When two stations are conversing on the FM channel, the repeater is not even a part of the operation unless one of the operators wants it to be (as for instance when the copy gets rough).

When a user wants to monitor the active 146.82 channel, but he is too far away from the area of activity to hear the stations, he merely puts a carrier on the channel and whistles into the microphone. Instantly the repeater comes on, regardless of the time of day or night, and the user finds himself right in the middle of the action. The only

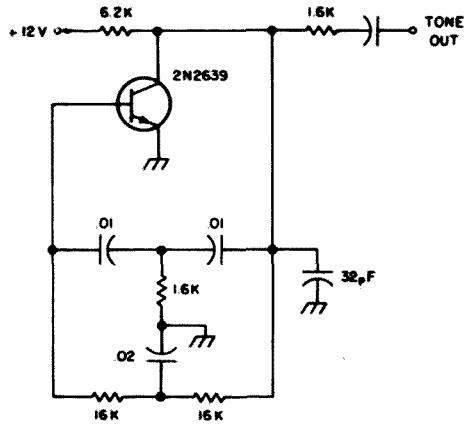


Fig. 1-1. Single-transistor tone oscillator for tone-burst or whistle-on use produces 1750 Hz at sufficient amplitude for most transmitters.

difference is that he hears the 146.82 action on some other channel.

The decoder at the repeater site that provides the turn-on function is nothing more than a simple frequency-to-dc converter such as the semiconductor decoder shown in the second article of this three-part series (included with this issue). This device is set to respond to as broad a range of frequencies as possible without being energized from ordinary conversations.

Even though the W6FNO decoder was set to respond to a wide frequency range, a few users found it difficult to key the repeater on by whistling. Perhaps their audio levels were not quite what they should have been to reproduce properly the required tone (1750 Hz), or perhaps they were simply not proficient whistlers. At any rate, I decided to install a simple automatic whistler in each of my transmitters.

The circuit is the epitome of simplicity: a single-transistor oscillator using a twin-T feedback network. As can be seen from the circuit of Fig. 1-1, a few minutes and a good junkbox are all that is required.

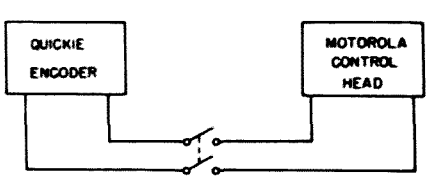

Fig. 1-2. A momentary-contact switch can be used as shown to interconnect the encoder audio into the mike line at the control head for whistle-on applications.

I didn't connect the whistler so that it would go on with each transmission. Not only would this have defeated the purpose of the repeater's automatic-off function, but it would have given my signal the unpleasant characteristic of a squeal at the outset of each transmission. Instead, I connected the device into the transmitter so that it is energized by pressing a momentary-contact switch on the control head. Figure 1-2 shows how the oscillator is interconnected into my Motorola mobile unit.

The oscillator circuit shown in Fig. 1-1 works for tone-burst entry applications, too, where the tone frequency tolerances are not particularly critical. But the interconnection would have to be a little different from that shown in Fig. 1-2. For tone-burst operation, remember, the audio note must appear for a short period every time the transmitter is keyed. A timing circuit for accomplishing this is shown in Part 3 of this series, Les Cobb's article entitled "Setting Up the Tone-Burst System."

Where the tone frequency is critically set, decoder instability is intolerable and whistling won't quite cut the mustard. For such applications, the encoder requirements become quite stringent. But it is possible to build a highly stable encoder unit with a minimum of parts. The circuit described below, for example, represents a very versatile transistorized encoder that can be built small enough to use with hand-held transceivers, yet stable enough for the most demanding applications normally associated with FM two-way communications. Because of its tiny size, I call the device a "microencoder."

A particularly attractive feature of the microencoder is the fact that it can be used for either continuous-tone squelch (commonly known in these parts as PL, for Private Line), or for tone-burst entry. As noted in the editor's introduction to this series, a continuous-tone squelch scheme utilizes a subaudible very low-frequency note, whereas the single-tone method depends on generation of a fairly high-frequency note. Most low-frequency encoders require vibrating reeds for stability; the one described here is a notable exception.

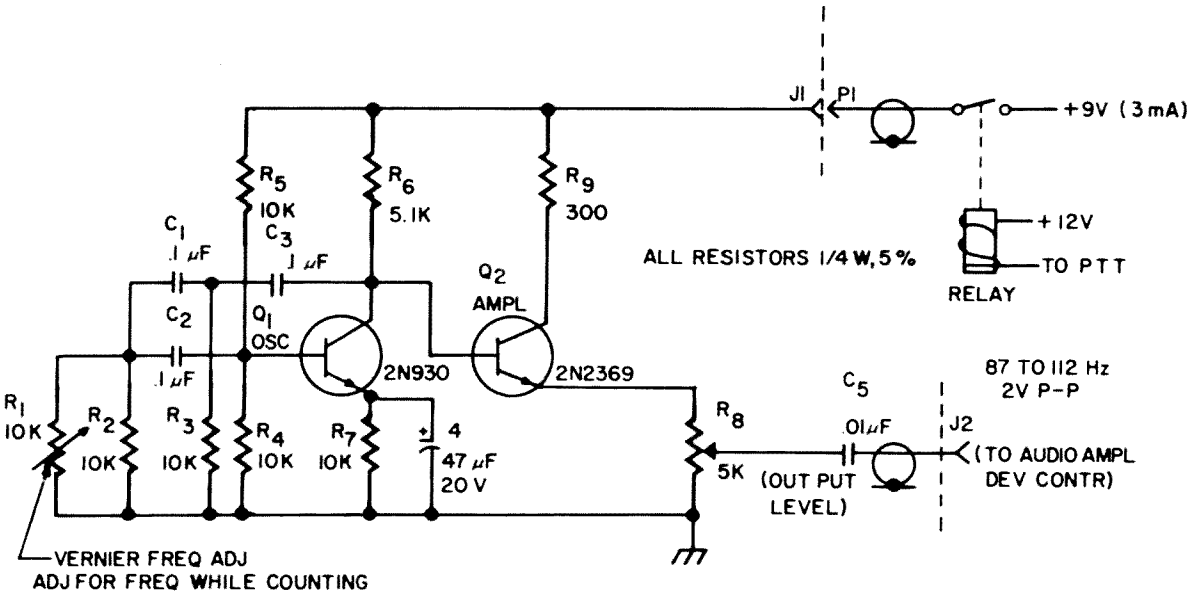

Fig. 1-3. Schematic diagram shows basic circuit as used in a continuous-tone-squelch repeater access system. Parts values shown are not applicable to single-tone encoder applications (see text).

Figure 1-3 is the schematic diagram for the unit, which is essentially a phase-shift oscillator coupled into an emitter follower. Since the power consumption of the oscillator circuit is so low, a standard 9V transistor-radio battery will provide an ideal power source. At full output, the oscillator draws no more than about 3 mA.

Table I. Parts Lists for CTS and Single-Tone Systems

Component	87—112 Hz range	1750 Hz
R1	10 pot (multiturn)	50K pot (multiturn)
R2, 3, 5	10K	47K
R4	10K	22K
R5	10K	47K
R6	5.1K	5.1K
R7	5K pot (multiturn)	4.7K 5K pot (multiturn)
R8	300Ω	300Ω
R9	0.1μF	0.001 μF
C1, 2, 3	47 μF, 20V tantalum	47 μF, 20V tantalum
C4		1 μF
C5	0.01 μF	tantalum
Q1	2N930	2N930
Q2	2N2369	2N2369

Table I shows two complete parts lists. The application of the encoder (continuous-tone squelch or tone-burst entry) will determine the parts selection for your particular use.

The very small size and the apparent simplicity of the microencoder might logically lead you to suspect its performance. But these factors notwithstanding, the device can produce a very healthy looking sine wave, as can be seen from the photo of **Fig.1-4**. Laboratory temperature cycling tests on the three units that I built indicate that the tone output will remain stable and will not drift more than 0.5 Hz over the range of 25-60°C. My units were built using disc ceramic capacitors, incidentally, substitution of Mylar capacitors for C1, C2, and C3 will undoubtedly result in even better temperature stability.

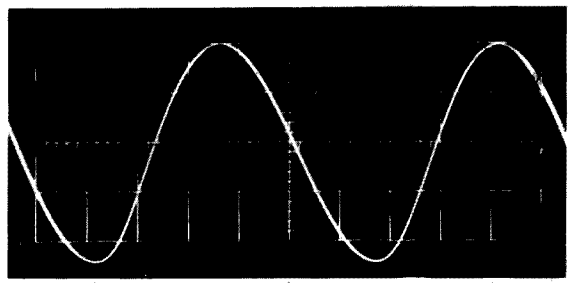

Fig. 1-4. Scope trace shows the sine wave obtained with the author's encoder unit. Increments shown are 2 msec per centimeter for the horizontal scan and 500 mV per centimeter for the vertical scale.

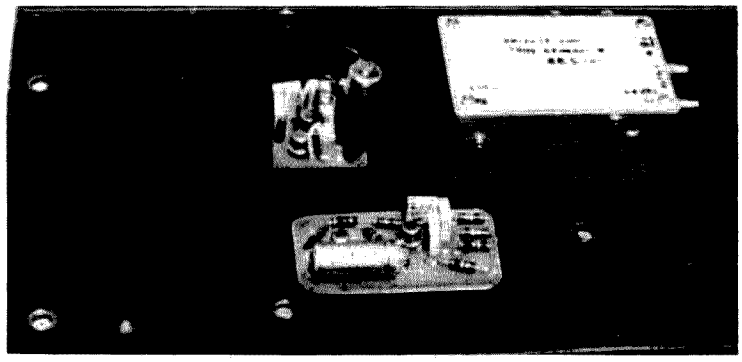

Photo shows three separate packaging schemes: printed-circuit layout; "cordwood" technique, and the "crystal-can" method, using a conventional Pomona Electronics miniature mounting box.

The schematic shows transistor Q1 to be a 2N930, but this type was chosen arbitrarily because it is something I happened to have "kicking around." Actually, any good NPN will suffice, as long as it is a type with a *beta* of 100 or so. The transistor used for the emitter follower is even less critical, and can be effectively duplicated with just about anything in the junkbox that has the same polarity.

As a continuous-tone-squelch encoder, the one mounted in my 41V has proved quite capable of keeping me communicating through the local toned repeater, which uses a GE KT-5 decoder to open the squelch with an input of 88.5 Hz. Another of the units, built from the other parts list, of course, very efficiently provides me with a 1750 Hz tone burst when I operate through the W6FNO repeater.

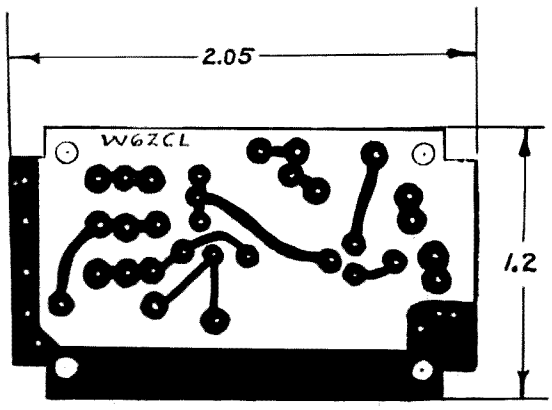

Fig. 1-5. Actual-size reproduction of printed-circuit layout. The copper side of the board is shown; components all mount from far side. (There is no copper on the component side.)

Figure 1-5 is a circuit board layout shown actual size. **Figure 1-5** is for those of you who intend to do the job up first class with printed-circuit wiring. The printed-circuit version looks sharper, of course, and it has the added advantage of ending up with a slimmer overall profile. The layout shown in **Fig. 1-6**, however, is perfectly satisfactory for "brass-board" models. This version requires nothing more than a few holes and some standoff terminals on a flat piece of almost anything.

The dimensions of the boards are suitable for mounting the completed unit inside a Pomona Electronics Model 2417 shielded box ($1.50 at practically any self-respecting electronic sales outlet). The low-frequency version that I am using is mounted on the inside rear chassis wall of my mobile 41V,

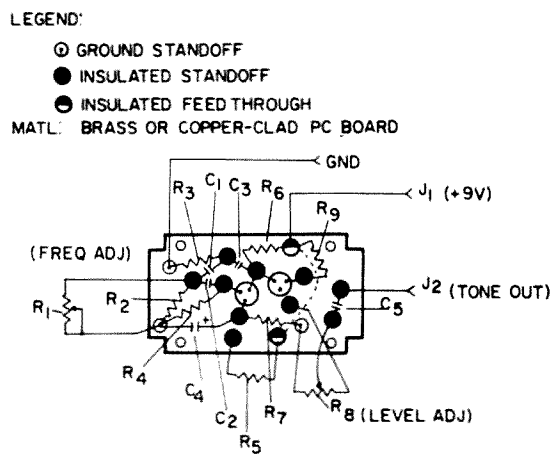

Fig. 1-6. Wired-board layout was designed for use with Sealectro push-in Teflon standoffs and ground terminals. Transistors can be held in place by TO-18 heatsinks. (Heatsinking is actually unnecessary. The cases of the transistors are hot and must be insulated from ground; the heatsinks perform this job by virtue of their anodized finish.)

immediately above the transmit crystals. I use miniature coax to apply the dc supply voltage (9V) and to carry the 88.5 Hz signal to the deviation control potentiometer through a 500 kΩ resistor, as shown in Fig. 1-7. If space is not available in the radio to mount the Pomona box, the printed-circuit board itself can be mounted in any available underchassis spot. The two variable resistors can be replaced without detriment by fixed resistors after the proper values have been

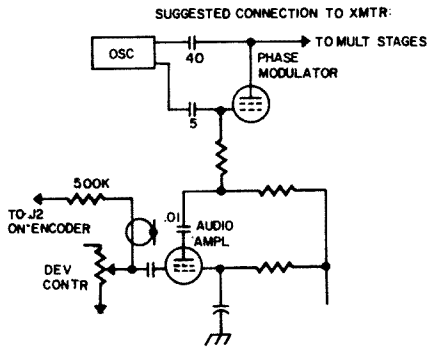

Fig. 1-7. Schematic showing manner in which the low-frequency version of the phase-shift oscillator can be tied into the transmitter.

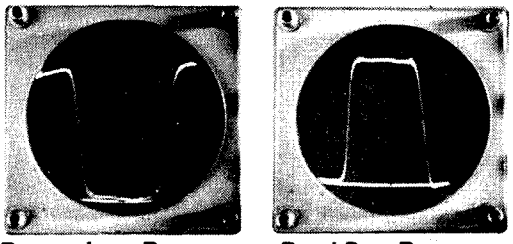
determined for your particular frequency and output-voltage level. But potentiometers are handy if you have the space. If you *can* use them, I suggest the use of the miniature multiturn devices (Bourns *Trimpots*), because of the vernier tuning they afford.

The parts lists shown in Table I cover the continuous-tone-squelch range of 87–112 Hz and the single-tone frequency of 1750 Hz. For those whose requirements are not met by either of these sets of values, the frequency of the encoder may be calculated from the equation

$$f = \frac{1}{2\pi\sqrt{6RC}} \qquad \frac{0.085}{RC}$$



If the single-tone version is used rather than the continuous-tone-squelch version, the audio need not be coupled to the transmitter as shown in Fig. 1-7. At these higher frequencies, it is practicable and convenient to simply mount the encoder unit inside the control head and connect the audio output lead from the oscillator directly onto the mike line. If you choose to adopt this method, just connect a 200Ω resistor in series with the tone oscillator output lead before attaching it to the carbon mike pin on the control head connector.

If the local repeater is the whistle-on variety (rather than tone-burst entry), you might also find it convenient to run the audio lead through a single-pole switch mounted on the control head. In this way, you can switch the tone on whenever you want it, and keep it out of the circuit the rest of the time. (A whistle-on repeater stays on after the tone is applied for a few milliseconds, and does not drop off the air until several minutes after the repeater is not occupied.)

For tone-burst entry applications, the timer circuit described in Part III will prove very worthwhile. With the addition of this simple timer, the oscillator can be made to key on briefly with each initiation of the push-to-talk circuit. (Again, a tone-burst-entry system requires a short fixed-frequency tone to accompany each incoming signal to be repeated.)

Part II: *by Ken Sessions, Jr. K6MVH*

Tone Decoder for Remote Switching Applications

The most critical element of a tone-access system is the decoder. When some problem exists in the encoder, or when the encoder frequency shifts a bit or when the encoding level goes up too high or down too low, the control operator can solve the problem with a few local adjustments. But when the decoder starts acting up, the impact can be a great deal more severe: In the first place, the decoder is installed at the repeater site, which is, more often than not, situated atop some remote mountain peak—miles (and sometimes hours) from physical accessibility. Second, while an encoder malfunction affects one individual's operation, a decoder problem affects the operation of every user of the repeater. Thus, care in building and sound conservatism in design are paramount considerations in deploying a tone control scheme.

I have had occasion to use many decoders during my days of remote control and repeater operation—some homebrew, some commercial. (Virtually every aspect of remote control involves the installation of a tone decoder somewhere along the way. And I can truthfully say that I have never come across a circuit that offered performance superiority over the one shown in **Fig. 2-1.**

I hasten to add that I can lay no claims as to design, for the circuit illustrated was conceived, built, debugged, and perfected by Bob Mueller (K6ASK), of Alhambra, California. Nor is this the first time the circuit has been published. I have incorporated copies of the circuit in past articles dealing with remote control of telephones, function selection in repeaters, and coded signaling for selective-call applications. It simply is a good sound circuit and can be applied wherever there exists a need to perform a switching function in one place by radio command from another place.

Decoder Requirements

The response curve of the decoder must be selective enough to preclude the possibility of off-frequency signals triggering the system, yet broad enough to allow decoding under a variety of input signal conditions.

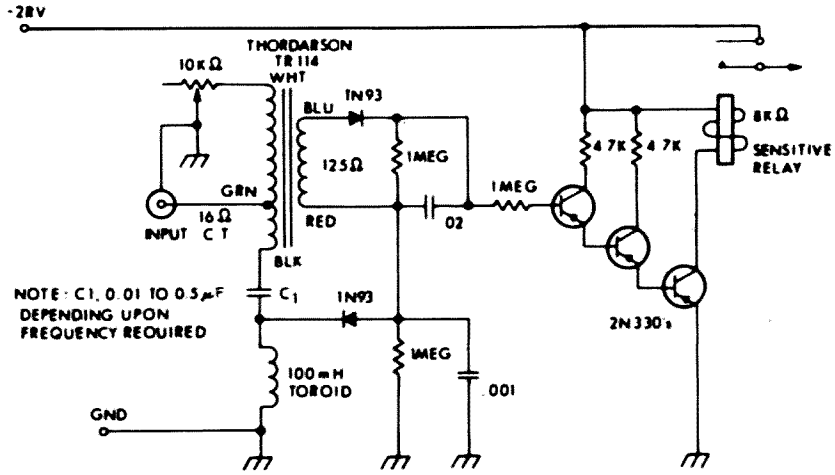

Fig. 2-1 Single-tone decoder.

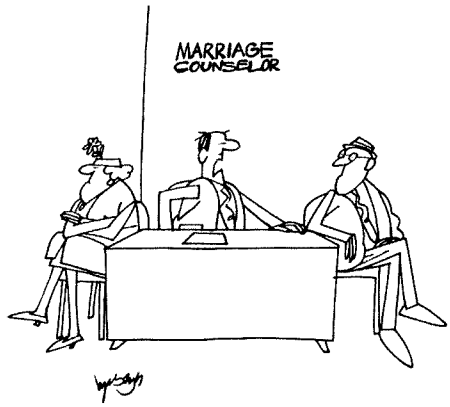
Ideally, a control should be available so that the threshold sensitivity of the decoder could be adjusted.



Adjustment of the input sensitivity accomplishes the effect of narrowing or broadening the spectral response of the device. At the least sensitive setting, the decoder has an input bandwidth of about 50 Hz. As the series resistance to the input of the transformer is decreased, the bandwidth widens. In the most sensitive position, the decoder will respond to a bandwidth that includes random noises and high-pitched voices. Thus, the decoder should fulfill the requirements of the whistle-on crowd as well as the more critical needs of the tone-burst fans.

The frequency of the decoder, using the values shown in the schematic, is 2300 Hz. This frequency can be shifted by the expedient of changing the value of capacitor C1. The 2300 Hz is fully appropriate for tone-burst applications, where voice tripping is to be avoided and whistle-on use discouraged. (The frequency is high enough to make whistling a difficult method of access.) It should be reemphasized, however, that whistle-on use of this decoder is possible—using the values shown—by simple adjustment of the sensitivity control of the input transformer.

Interconnection

The simplest part of getting a tone-access system to work is the interconnection of the decoder itself. All you have to do is provide the proper power to drive the transistors and relay, then connect the speaker audio from the repeater receiver to the low-impedance input of the decoder. After that, it is simply a matter of making a few adjustments with respect to level (at the decoder input and at the receiver output). When the controls have been properly set, an incoming tone of the correct frequency will cause the plate relay in the decoder to close. Use of the relay's contacts is a matter that is best left to the judgment of the repeater owners. If you're short of ideas, however, you might just read on. Part III tells how to go about setting up a complete tone-burst-entry repeater system. And the decoder described here will fill the bill nicely for that application.

Part III: *by Les Cobb W6TEE*

Setting Up the Tone-Burst System

Among the various techniques for selective control of remote devices, including repeaters, one of the simplest is tone-burst keying. This method consists of a short burst of a specific audio tone automatically sent at the start of a transmission. In a repeater application, a burst detector (see Part II of this three-article series) is used in conjunction with the carrier-operated relay to activate the repeater transmitter upon reception of the proper burst frequency, and to hold it on as long as the incoming carrier is present.

The simplicity and versatility of tone-burst keying should not be overlooked where a simple control or selection function, not related to primary control, is required. As an example, the number of 146.34-to-146.94 repeaters on the air or being built in Northern California and Nevada was such that it became obvious that overlapping input coverage was going to cause unintentional keying and interference to adjacent machines. To obviate this, a tone-burst frequency allocation plan was agreed upon. As shown in **Fig. 3-1**, the plan covers four repeaters and one remote base station with a burst-protected 146.94 receiver.

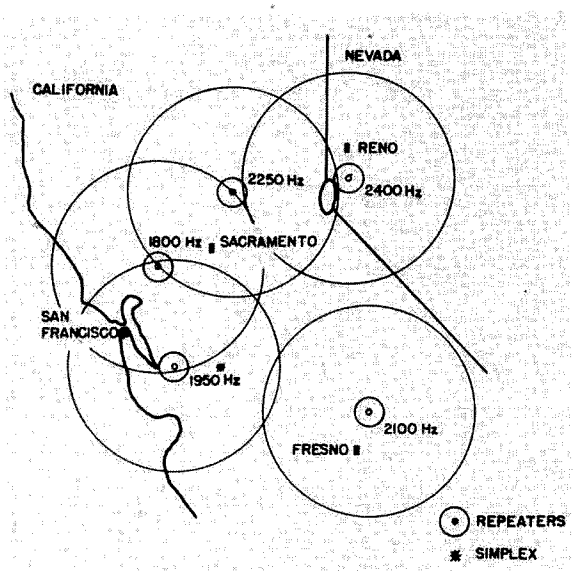

Fig. 3-1. Tone-burst entry plan—34/94 repeaters—No. Calif./Nevada.

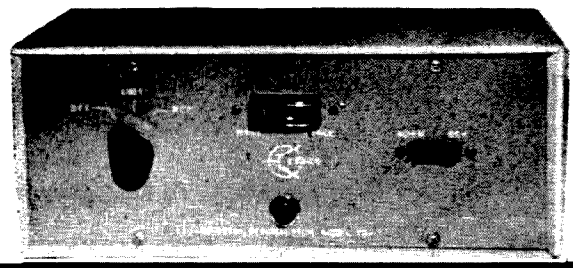
While it is admitted that the tone-burst approach does not solve all of the problems associated with overlapping repeater coverage, it certainly tends to minimize them by permitting the users to call for only the particular repeater needed for a given two-way communication exchange.



If tone-burst entry is used on open repeaters on the nationally adopted frequency of 146.34, some semblance of standardization should be maintained to give travelers some hope of universal access capability. Partly because of the abundance of Motorola equipment, the frequencies long considered standard by Motorola are most common in amateur use. The following frequencies are stock outputs for the Motorola P-9301A encoder: 1800, 1950, 2100, 2250, and 2400 Hz.

In amateur service, there are many tone-burst systems operating in the 1700 to 1800 Hz range, but these lower frequencies might better be reserved for whistle-on use because of the ease with which they can be orally reproduced.

For those wishing to use commercial equipment, the Motorola P-9301A encoder and P-9303 decoder are available on the surplus market. More recently, the Motorola SP-1005-TAAE solid-state under-dash oscillator has become available. This unit has a selector switch and can generate all tones from 1800 to 2400 Hz, in 150 Hz increments.

But if you've a mind to build up the encoders and decoders, the circuits shown in

the accompanying articles should do nicely. That leaves only the problem of interconnection.

When an encoder such as the one depicted in Part I is used, some means must be employed to limit the oscillator's output to no more than a half-second or so with each keying of the transmitter. To accomplish this, the timing circuit shown in **Fig. 3-2** was developed by K6GUC. In his approach, the 12V supply for the encoder must be keyed on and off with the transmitter.

At the repeater site, some wiring must be done at the decoder to keep the transmitter locked on for the duration of a carrier, even though the tone itself drops out. **Figure 3-3** illustrates how this might be easily achieved. The repeater control relay (K2) should be fairly husky; it can be driven directly by the decoder relay (K1). It is not wise to derive the K2 switching functions by wiring the contacts of K1 directly, because K1's contacts are likely to be of a delicate nature. K1 is a sensitive, current-operated relay and its contacts are best used for no greater requirement than to control a heavy-duty dc relay.

HOW TO VISIT FOREIGN COUNTRIES

by Wayne Green W2NSD/1

A reader, about to make a trip abroad, asked for hints on how to get in touch with amateurs in foreign countries. As one who has done this sort of thing a lot, I think I have some helpful ideas.

First, by way of preparation, I devote several weeks to intensive activity on 20 meters. I look for contacts in the countries I am about to visit, and I find that these contacts almost invariably lead to interesting invitations to dinner and sightseeing. They also lead to my getting to meet many more of the local amateurs.

I follow up my contacts with a QSL card and a letter giving my itinerary in detail for my trip. If I am going to be met at the airport, I try to make sure that my DX contact knows just what flight I will be on, and I let him know immediately of any plan changes. I realize that he will be taking a lot of trouble on his end, rearranging his work schedule, his family plans, and setting up meetings with friends, so I try to be as considerate as I can. If I am not traveling a long distance, I phone ahead and let him know that I am on schedule.

It is well worth while to write ahead to the secretary of the national amateur radio club of the country you are going to visit. The club officer can arrange for you to meet a representative and this often leads to introductions to local amateurs, visits to club meetings, and even getting in touch with someone to stay with on occasion.

If you are interested in operating, the club can often help you to get an operating permit and may even have a club station available for you. If you use the call letters of the station, often no permit is required and all you have to do is just sit down and operate. I have done this from dozens of countries. Always offer to take care of the QSLing brought on by your operating.

Rare Countries

There are very few rare countries where there is not even one active amateur. If you are going to DXpedition to a completely inactive country, you will have to bring

along your own equipment, obviously. This is expensive and difficult, as any reading of articles by DXpeditioners makes very clear. For my part I avoid countries of this rarity and try and stick to those that have at least one active amateur.

I have found that the amateurs in rare countries are all too happy to have me visit and sit down for a day or so at their rigs and rack up a few thousand contacts. The pressure for contacts and more contacts every time they get on the air gets to be depressing after a while, and they tend to limit their operating time or keep out of the American phone band. In just a couple of days I can take a lot of this pressure off.

English is the native language for very few DX operators, so I find that under QRM conditions I can make contacts many times as fast as can the local op. Knowing English, I can sort out call letters quickly from the mass of calling stations.

Even when I visit relatively common countries I find that I get pileups. When operating from 5Z4ERR in Nairobi I gave contacts to a lot of the lower power stations that normally miss out on DX. Further, I found that I was in great demand by mobile ops by the dozens. My system of working right down to the weakest signal in each call area made it possible to work even the flea-power stations.

When I visited FK8 I found that the country was in great demand because almost all of the local ops spoke only French. The FK8 ops appreciated my getting a few thousand W's off their backs by giving them a contact with their country. Ditto FO8 in Tahiti.

Your trips abroad will be infinitely more fun if you make arrangements to visit amateurs. They will wine and dine you, show you their city and country, just as you would them. They will offer to put you up and they will get in touch with friends in the cities along your path. You will have an opportunity to explain the U.S. to them in a way that no Hollywood movie has ever done. You will also have a chance to find out anything about their country that you want to know, just for the asking. And they will love you for being interested enough to ask.

WHERE DO YOU FIT?

The FCC regulations give as the purpose of amateur radio:

(a) Recognition and enhancement of the value of the amateur service to the public as a voluntary noncommercial communication service, particularly with respect to providing emergency communications.

(b) Continuation and extension of the amateur's proven ability to contribute to the advancement of the radio art.

(c) Encouragement and improvement of the amateur radio service through rules which provide for advancing skills in bot the communication and technical phases of the art.

(d) Expansion of the existing reservoir within the amateur radio service of trained operators, technicians, and electronics experts.

(e) Continuation and extension of the amateur's unique ability to enhance international good will.

The DX-35 REVISITED

A few tips for modernizing the old standby

Many of us, when we first started in amateur radio as a Novice, purchased the Heathkit DX-35. This transmitter was capable of 75W input and was running quite hard to achieve this power level. The oscillator and final were both keyed, so with certain crystals there was an inherent chirp.

We were contemplating the use of the DX-35 as a CW exciter for a kilowatt linear. Our main goal was to modify the circuitry of the DX-35 to improve the efficiency and eliminate the chirp.

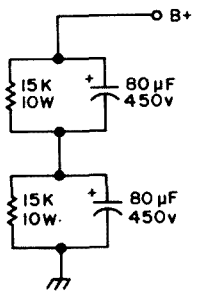

Fig. 1. Existing 20 µF capacitors can be replaced by 80 µF cans to up the filtering to 40 µF total.

The first modifications to be made were in the B+ filtering circuit. Normally, two 20 µF, 450V capacitors were being used in series to give a total of 10 µF, 900V of filtering. We replaced these paper capacitors with can type 80 µF, 450V capacitors to give a total of 40 µF for filtering (See **Fig. 1**). Appropriate holes were cut in the chassis so as to mount the can type capacitors. One of the capacitors will require an insulating mount to isolate it from the chassis due to the fact that these capacitors are in series. The original equalizing resistors (15 kΩ, 10W) were retained and placed in parallel with the new capacitors.

The 5U4 rectifier was replaced with a 1N1239 silicon rectifier unit. This solid state rectifier plugs directly in the socket of the 5U4. (An alternate method is to build up your own replacement in the base of a broken 5U4.) You conserve on power transformer drain through the use of this because the 5V filament source is no longer necessary. The solid state rectifier will also provide an increase in total plate voltage.

We had received reports of chirp using the DX-35 as a barefoot transmitter. Of course this would be undesirable when using the linear. A considerable voltage drop was observed on the oscillator plate when the transmitter was keyed. Also, both the final and oscillator are keyed. We removed the cathode grounding lead of the oscillator from the front panel keying jack and ran this to a single-pole toggle switch that was also

mounted on the front panel. This switch was wired so as to ground the oscillator cathode and allow the oscillator to run at all times when the final was keyed. Less chirp was noticed but there was still a small amount present.

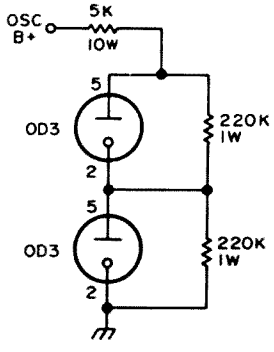

Fig. 2. The 220 kΩ resistors across the series regulators help to equalize the oscillator voltage distribution.

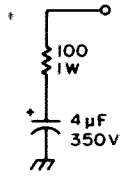
The next step was to get rid of the voltage variation on the oscillator that was present when keying. Two OD3 regulator diodes were placed in series to give a 300V regulation level. Resistors (220 kΩ, 1W) are paralleled across the OD3's to equalize the voltage and a 5 kΩ, 10W current-limiting resistor was placed in series with the OD3's (**Fig. 2**). This assembly was inserted between the oscillator B+ and chassis ground. The voltage on the 12BY7 oscillator now remains at 300V during the keying sequence, and the chirp is eliminated.



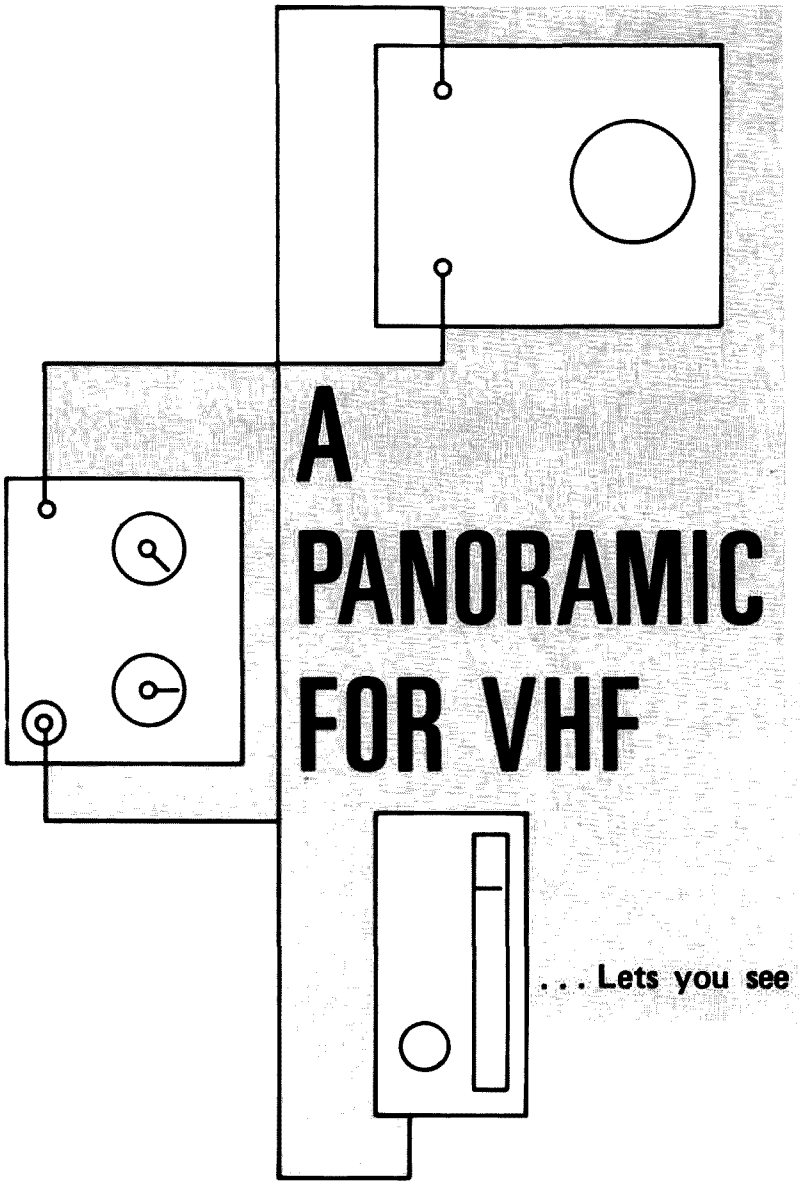


Fig. 3. Keying shaping circuit.

Though not really necessary, we added a keying shaping circuit consisting of a 100Ω, 1W resistor in series with a 4 µF, 350V capacitor. This circuit shown in **Fig. 3**, goes from the keying "hot" lead to ground.

A PANORAMIC RECEIVER FOR VHF

. . . Lets you see the whole band at once

One of the more typical aspects of my father's (I1LOV) personality is that he wants something new in his ham shack every day, and this requires a lot of brainwork from me, to satisfy his never ending need for strange gadgets.

A few evenings ago, he was as usual having his complicated QSOs on 2 meters, tuning the band with three different receivers at the same time, when he said, "How nice if I could take a look at the complete band, and know every moment what goes on the air."

There was no possibility of mistakes! I lighted a cigarette, as usual, before I went to explore in the junkbox and began to work. A day later, there was the panoramic receiver, with his calibrated scale showing up every signal on the 2 meter band. And now the complete story.

The first approach was quite fast. I took a generator, injected a sweep signal in the socket of the crystal in the local oscillator of the converter (144-28 MHz), connected the oscilloscope to the last i-f in the receiver, and in a few minutes I had the band on the screen (Fig. 1). But the local oscillator wasn't working properly, and sensitivity wasn't very high.

If you are a lazy fellow, have a scope and a sweep generator, and a few extra converters for the various VHF bands, this is the

job for you. For me, it was nice to see that everything worked as it should, but I was sure that there was a simpler approach, one requiring no modifications in the converters, and giving the possibility of hearing and seeing with only one antenna and one converter. So, it was clear I had to work on the tunable i-f receiver. But you cannot put your hands in the station receiver, especially if it is a 75A1 or 51S1, as it was in our case; so, there are two possibilities: you have some old i-f receiver around, or you build it. Fortunately, I found an old receiver I had made some years ago, a double conversion unit with no rf stage in it.

I disconnected the tuning capacitor from the local oscillator coil and connected a varicap diode in parallel. A wire from the sawtooth generator in the scope furnished the sweeping voltage. A few more modifications to the detector and first audio stage, and the output of the receiver went to the vertical plates of the oscilloscope. After a bit of tuning, the panoramic receiver was ready to monitor the 2 meter band.

Principles of Operation

A few words to explain how it works for those who are not acquainted with oscilloscopes, sweep generators, and panadapters. In every oscilloscope the trace you see is the result of the rapid sweep of the luminous spot across the screen which is produced by a sawtooth voltage applied to the horizontal plates. Now if you apply an ac voltage to the vertical plates, the spot will be subjected to a double force, one compelling it side to side, and the other up and down. Let us assume that the frequency of the alternating voltage driving vertical plates is two times that of the horizontal ones. Then in the time it takes to go from left to right, the spot will be deviated up and down twice, and will show a two-period sample of the voltage under examination.

Now, if the vertical plates of the oscilloscope are connected to the detector of the receiver, a signal will appear on the screen every time the receiver is tuned to a station. Now, imagine tuning across the band very fast—exactly as fast as the spot on the screen runs on its way from left to right. If you tune a full megahertz while the spot makes a trip, you will see a pip on the scope every time a signal is tuned in. This is due to the fact that the signal generates an output voltage only during the short time in which its conversion frequency allows it to pass through the narrow bandpass of the receiver's second i-f. If you tune from 5 to 6 MHz, the left side of the screen will be 5.0 and the right side 6.0. Every signal will show up on the scope in a place on the screen in direct relation to its frequency. Now the problem is that you cannot manually tune your receiver up and down. This function is provided by a Variac, to which is applied the same voltage that sweeps the trace. This provides synchronization between the scope and the receiver local oscillator.

Circuit Description

The receiver circuit is quite conventional and requires only a little care in isolating the circuits working at different frequencies to prevent spurious responses that will appear as pips on the screen. The input signal is link-coupled to the grid coil of an EC88 triode mixer. (You can use a 6AM4, or

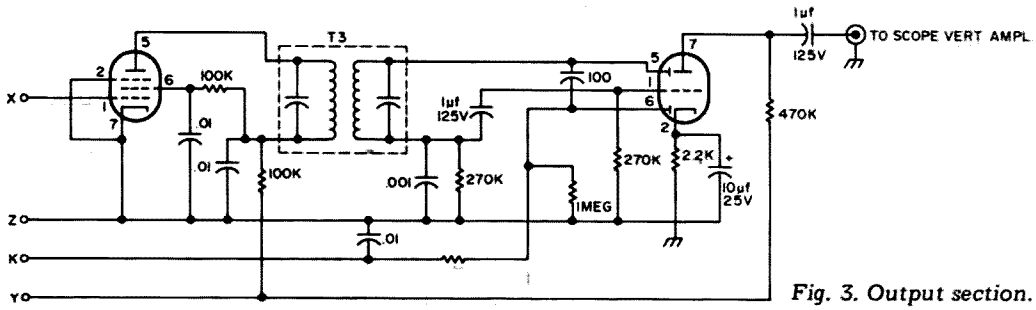
something like that; any rf triode will work.) A BA 102 (5–15 pF range), driven by a sawtooth voltage coming from the scope's sweep generator, is connected across the grid coil of a 6J4 local oscillator, sweeping its frequency from 21.120 kHz to 23.120 kHz to provide a first i-f of 6.8 kHz. A 6U8 second mixer local oscillator converts this signal to 455 kHz with a quartz crystal resonating at 5.425 kHz. I was compelled to use such unusual i-f frequencies by the crystal I had on hand. You can try other combinations, but be sure you don't use a first local oscillator frequency starting at 24 MHz; otherwise, you will have a spurious response at 144 MHz that will probably be heard by your VHF converter. The same care in selecting the second oscillator's quartz crystal must be used in order not to have spurious responses in the 28-30 MHz range. Two 6BA6 stages at 455 kHz provide plenty of gain and are very stable, showing no tendency toward oscillation. One diode section of a 6AT6 tube is the detector, the other provides a little agc, while the triode section is the video preamplifier. You can omit it and use a crystal diode if your scope has a multitube vertical amplifier. B+ voltages are provided by a GZ34 full-wave rectifier. As you can see from the photo, screening is provided between rf and first i-f stages and 455 kHz i-f section.



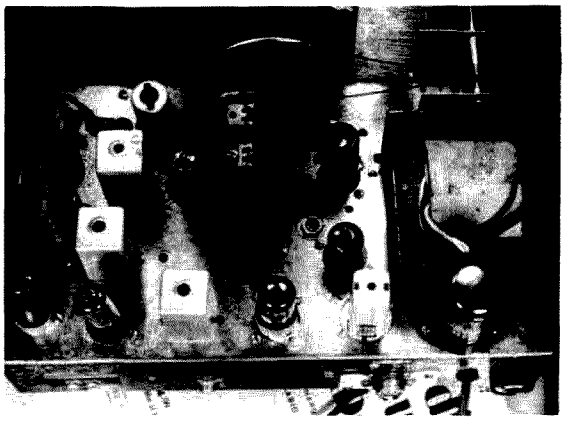


Fig. 3. Output section.

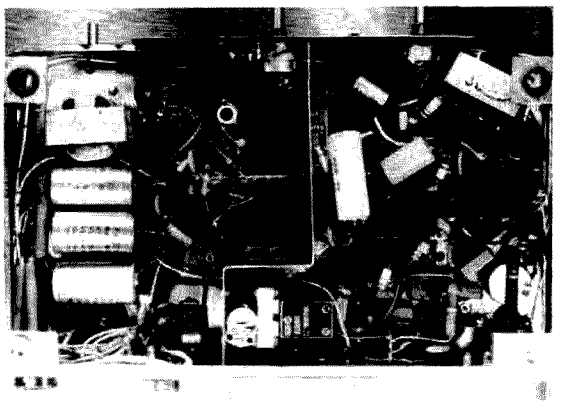
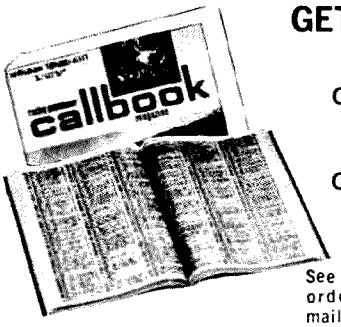


Top view of panoramic receiver.

Construction Details



You can get an idea of the disposition of the various parts by looking at the photos. (The tuning condenser and the screened tube near the last i-f transformer are no longer in use, due to the fact that the receiver was built as a normal audio unit.) As you can see, the power transformer is a very big one. You can simplify the supply without degrading the performance of the receiver. This will allow you to use a smaller chassis.

The positions of the various components are not too critical, and you have only to be careful that you make good ground connections and use good quality bypass capacitors. As shown in the picture, I used a lot of big old mica capacitors from surplus strips. In the rf and i-f stages, connections should be as straight and short as possible. Bypass every hot filament pin. Coil L3 is a 10.7 MHz i-f transformer, and you must modify it to tune around 7 MHz. Take the coil out of its can and parallel small-value capacitors to

CONNECTICUT'S OLDEST HAM STORE

the internal ones, if any, until you find resonance around 7 MHz (with the slugs half in) on a grid dip oscillator. After that, you can close the cans again. (Mine tuned with 50 pF.)

The crystal controlled local oscillator is very simple, with nearly nothing to tune, and starts without any difficulty. Coupling is provided by a 1 pF capacitor from pin 9 to pin 2. A few twisted turns of wire work equally well. The i-f amplifier, having a very high gain, requires a little care. Short wiring, bypass capacitors connected to the i-f transformers where the leads enter the cans, and eventual shielding connected across the tube sockets will keep everything quiet.

My receiver was built on a normal chassis (that of an old S-102 Hallicrafters 2 meter receiver), but the second time, I found that it is much easier to build converters and little receivers on printed circuit boards. They are easy to drill, offer a very good, easily soldered ground, and you can readily make a chassis of any dimensions you want, and begin to build while you wait for the box to be made.

Tuning Up

First, connect the vertical amplifier of your scope to the video output of the receiver. Then, with no B+ on the 6U8, 6J4, and EC88 tubes, connect a 455 kHz generator to the grid pin (2) of the pentode section of the 6U8 tube, and tune all the slugs in the 455 kHz i-f transformers (beginning from the last one) for maximum height of the trace. Keep the output from the generator as low as possible, consistent with a readable trace on the scope. Too much output will cause distortion, and no more trace height. Repeat two or three times. Next, connect B+ to the 6U8 tube. The local oscillator should start immediately. Connect the generator, tuned near the first i-f frequency (6.88 kHz in our case) to the grid pin of EC88 tube, and try to get an output (be careful not to tune on the image, which is about 900 kHz lower than the fundamental. Tune the slugs in L3 and trimmer capacitor from pin 9 of EC88 for maximum output. Now disconnect the 10 kΩ resistor in parallel with L1 and tune it at 29 MHz with a grid dip oscillator. Find the sawtooth generator tube in your scope. Normally, when the sync selector is in the internal position, the output from this tube is connected across the "horizontal gain" potentiometer. Be sure that there is no high voltage on this control. With a VTVM or a scope, verify that there is 5–10V of the sawtooth voltage between the hot side of the potentiometer and ground.

If everything is right, connect a shielded wire from the hot side to the "sawtooth input" in the receiver. Now, connect B3 to the EC88 and 6J4 tubes. With the generator connected at the antenna plug tuned at 29 MHz turn R1 (sweep width control) till you see a pip on the center of the screen. Rotate the sweep frequency of the scope till you get the narrowest pip. (Sweep frequency must be as low as possible, around 30–60

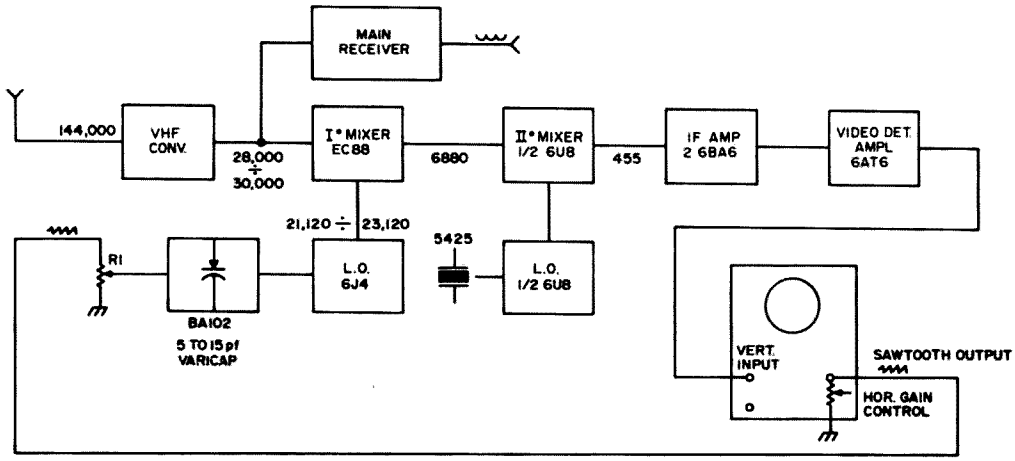

Fig. 4. Block diagram, final assembly

ANTENNAS, INC. can be your one-stop, single-source. Write today for our catalog . . . no charge of course.

Hz.)Tune around with the generator and notice how many MHz you are seeing on the scope. If the sweep is too wide or too narrow, rotate R1 till you get the wanted width. Now, with the generator again at 29 MHz, recenter the pip on the scope, turning the slug in L1. Repeat the preceding steps several times, till you get the wanted bandpass.

If you are not interested in the center frequency being at the center of the screen, with slight adjustments, you can put 28 MHz at the left side and 30 MHz at the right side of the screen. (Naturally, if you want, you can select other frequencies, from about 26 to 32 MHz just tuning the slugs, with up to 4–5 MHz bandwidth.) Now, tune L2 for maximum response at the center of the trace, and select a swamping resistor that gives an equal response in every point of the trace. Usually, the 10 kΩ unit marked on the diagram will do, depending on coil Q and the desired bandpass width.

Scope trace

Now you can calibrate the screen with a frequency scale. As you can see from the photo, the scale is not linear, as in any capacity-tuned oscillator. Another source of nonlinearity can be an irregular sawtooth tension. Differences often found in inexpensive varicaps make it difficult to track oscillator and antenna coils. The first time, I tried to track L2 with another varicap fed with sweep voltage (you can see two little black controls near L1), but that resulted in sweep noise coming into the station receiver, and this approach had to be abandoned. This happens when the 2 meter converter used for the panadapter and the receiver is the same.

Now you can connect the output of your VHF converter to the panoramic receiver and *see* the band. If there is too much "grass," it is better to reduce it, detuning the last i-f transformer a little instead of reducing the vertical gain on the scope.

On-the-air Performance

It is possible to see many signals just above the noise level. (In the photo you can see six). The panoramic view proves useful on many occasions—to have an idea of activity on VHF, while working other frequencies, for roundups, for turning the antenna to the best compromise position in a multisided QSO, to tune VHF converters, for zero beating, etc.

The best part: I got a reprieve, of sorts. This toy has kept my father busy enough that he's lost the kick for something new every day.

VARIABLE-IMPEDANCE MOBILE MOUNT

By far the most popular mobile antenna is the center load coil variety. These come in various sizes, shapes, and colors, depending upon the whim of the manufacturer. The New-Tronics model, for instance, comes in a quiet shade of gray, and depending upon power rating and frequency, varies between about ½" and 2" in diameter. Waters Manufacturing favors black for the color and has an assortment of shapes for the coils. Webster has recently come out with a new KW series. The coils are white in color. They are sometimes referred to as the "White Bubble."

Each of these has its advantages, and efficiency varies from band to band. So it is highly possible that one might use different coils and tips for different bands. In my particular case, the Webster KW-80 has proved very successful for 75 meter operation. However, on a long trip, multiband operation using the Waters 75 meter coil with the Band-Adder (see Dec., '67, *73 Magazine*) makes it possible to operate 10-15-20 and 75 without getting out to change coils.

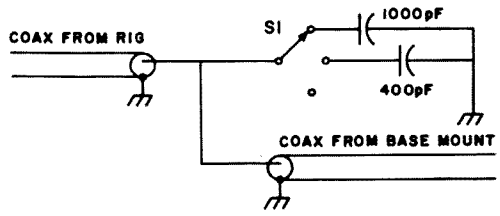

Fig. 1. Schematic diagram.

Waters and New-Tronics claim a 52 ohm match and require no further matching device. Webster suggests the use of some type of impedance matching on 80 and 40 meters. Tests have shown that a 1,000 pf silver-dipped mica capacitor from the center conductor to ground provides a good impedance match on 80, and a 400 pf capacitor provides the proper match on 40. No matching is required on 10-15 or 20 meters. Now, let's face it – connecting and disconnecting capacitors at the base of the antenna every time you want to change bands becomes Excedrin Headache No. 74.

After knocking heads with Bill McCracken, K1GUU, we came up with this nice little switching arrangement. In this case, a deck mount is used. A ceramic switch and an Amphenol SO239 connector have been mounted on a bracket attached to the backing plate. The two capacitors have been connected from the switch to ground, leaving one position a direct connection with no capacitance added. In this way it is a simple matter to hop out of the car, change the coil and tip, and merely turn the switch to the position required for the given antenna. My thanks to Bill for the actual construction.

lossy transmission lines

An amateur I contacted the other day said he was using a 10 meter dipole for 20 meters and was getting an swr of 1.2:1 —which is hard to believe. He said his "swr is low and the transmitter loads up" and therefore he was perfectly happy with this arrangement. However, on 40 and 80 meters, he could not use this 10 meter dipole since the swr was greater than 8:1.

The idea of a two-band dipole intrigued me, so I pressed for more details. He was using 200 ft of RG-58/U coax and a 1 kW amplifier. The weather was cold (New England winter), he was getting out, and therefore he was not about to change this arrangement.

His transmission line was acting as a "loss pad," an impedance matching scheme which is used extensively in audio work. A loss pad can take the form of a T, H, ladder, or even a simple series resistor. Its gain is always less than unity.

Consider the simple case of a 5 kΩ plate load to be matched to a 10Ω voice coil. A perfect match results if a 4.99 kΩ resistor were put in series with the 10Ω voice coil. But look what happens to the useful power output. Approximately 1/500 of the power appears across the voice coil and the rest is lost as joule heat in the resistor.

This also reminds me of two experiments which I developed for lecture demonstrations. In one experiment I load up a pair of oldfashioned bedsprings connected back-to-back in dipole fashion, gamma matched, to perfect swr. The transmitter loads up but there is little radiation.

The other experiment uses 225 ft of RG-8/U coaxial line of mongrel origin which shows good swr but blisters badly when 1 kW is pumped into it.

STAFF

Part XIII: Examining Filtering and RTTY

In the beginning, ham radio had only one kind of communication available—telegraphy, using a hand key. (We can't call it CW, because in those days continuous-wave transmissions didn't exist; spark gaps generated the rf.)

As the years passed, the spark gave way to CW, and telegraphy gave way to voice communications to some degree. Voice work was all done with AM originally, but as the art progressed FM and the many varieties of sideband joined the procession.

Today, ham radio has its choice of many kinds of communication techniques. Hand-key CW, automatic-key CW, AM voice, FM voice, SSB, and DSB are the most widely used, but facsimile, television, and digital telegraphy (more commonly known as RTTY) are also very much in the picture.

Since the Extra Class license is the highest grade issued in the Amateur Radio Service, the FCC rightfully insists that aspirants to this ticket be familiar with the entire range of techniques available to hams. As a result, the examination for the Extra Class license includes questions on the lesser-used techniques as well as on the more common practices.

In this section of our study course, we'll look at some of these more specialized questions. Specifically, we'll cover the subjects of RTTY and filtering. On the official study list, these subjects are the basis of the following questions:

5. What is meant by "frequency shift keying" and how is it accomplished?

13. Draw a block diagram of an RTTY system showing the primary function of each stage. What is the proper way of identifying an RTTY transmission? What is the most widely used frequency difference between the mark and space frequencies in a conventional RTTY transmitter?

41. How do filters attenuate harmonic emissions?

49. If a crystal lattice filter has bandwidths of 3 kc/s at the 60 dB points and 1.5 kc/s at the 6 dB points, calculate the shape factor. At what frequency is the best shape factor achieved in a crystal lattice filter?

64. How do phasing condensers help stabilize crystal filter circuits?

Following our usual practice, we'll supplant these highly specific questions with a set of more general questions for our discussion. This time, we will actually have two sets, one for each of our two subjects.

The starting point for RTTY is most general—"What is RTTY?" Filling out this subject is our second question, "How is RTTY transmitted and received?"

On the subject of filters, we must be almost as general and begin by asking, "How do filters operate?" We can then ask, "How is filter performance rated?" and finally become a bit more specific when we examine "How are rf bandpass filters constructed?"

Radioteletype

What Is RTTY? The first electrical communications technique was, of course, telegraphy. Samuel F. B. Morse is generally

credited with the invention of telegraphy (although, like Marconi in the case of radio, Morse's major contribution was to gather a number of discoveries made by others into a working system and promote it to the world). The familiar hand key was, for several decades, the only means of originating any electrical communication.

As the years passed, a number of inventors attacked the problems imposed by the hand key and its requirement for an operator who knew the telegraphic code. Eventually, Joy Morton and Charles L Krum developed a machine which was able to bypass the operator requirements. It was, essentially, a cross between a typewriter and a telegraph system. In 1915, the Associated Press adopted the Morkrum machine.

Meanwhile, Edward Kleinschmidt independently came up with a machine to perform the same purpose. In 1925, the Morkrum and Kleinschmidt companies merged, and five years later AT&T bought the firm. The machine was named "Teletype" by blending the prefixes of "telegraph" and "typewriter," and the firm was named the Teletype Corporation. The word "Teletype" is, incidentally, still a registered trademark of the Teletype Corporation and cannot legally be used to refer to any other make of teleprinter equipment. Its common abbreviation, "TTY," is not a trademark and can be used as a general term.

TTY machines were designed with the requirements of land-line telegraphy in mind, but during World War II it became apparent that radio transmission could replace the land-lines with little change in techniques—and RTTY (radio TTY) was born.

Amateur RTTY got its start in 1946 when a number of hams on both coasts, in a parallel but apparently unconnected action, persuaded several companies to release obsolete machines to ham use instead of smashing them for junk.

Today, TTY equipment has many uses besides the original land-line telegraphic application, and as a result machines are not too difficult to locate. For instance, TTY equipment is widely used in the digital computer industry (where the machine is known as a "remote terminal") and as of the summer of 1969, at least a dozen firms were producing machines for this purpose which had never participated in the telegraph-communications use.

The principle upon which TTY operates is similar to that of normal CW transmission, with one major difference. Where CW makes use of five different kinds of signals—dits, dahs, and three lengths of spaces to indicate in-the-character space, word space, and sentence space—TTY uses only two. The two kinds of signals used by TTY are called "mark" and "space" and may be represented in several different ways. The advantage gained by using only two kinds of signals is that a machine can then interpret the signal with a minimum of "logic" or decision-making circuits; conventional CW with its one-unit dit, three-unit dah, and one-, three-, and five-unit spaces would require much more interpretation to decode. This is simple for humans, but most complicated for a machine to perform (although machines *have* been built to do so).

Because of the differences in the kinds of signals used, TTY equipment does not employ the International Morse Code. Instead, it uses one of several other codes which assign characters to combinations of the mark and space signals. Amateur and most commercial equipment uses the "International Five-Unit Code," but equipment designed for use with computers is more likely to employ the "American Standard Code for Interchange of Information" or a different code originally introduced by the Friden Company for its "Flexowriter" equipment.

Regardless of the code used, the signals sent and received by a TTY machine consist of groupings of "mark" and "space" signals. At the machine itself, "mark" is usually represented by the presence of current in the line, and "space" by the absence of current, so that they can be thought of as "on" and "off" conditions. This same representation *can* be used in the circuit from one machine to another, and the result is known as "make and break keying." Ordinary CW is sent by make and break keying, for instance. For the machines, however, the use of make and break keying makes it impossible to distinguish an extended "space" condition

from a circuit failure and resulting total loss of signal—and so other representations are usually employed instead.

The most common technique used to represent "mark" and "space" conditions in RTTY is to use two radio frequencies rather than just one. One frequency represents "mark" and the other is "space." Now a loss of signal can be recognized by the absence of *both* the mark and the space signals, while an extended "space" condition is signaled by the presence of the space signal.

The two frequencies are usually very close together. The difference between the mark frequency and the space frequency is known as the "shift," and the normal shift is only 850 Hz. This tends to minimize fading because the two signals will fade together. Narrow-shift is also used, with a shift of as little as 150 Hz, to minimize fading effects still more. Any shift less than 900 Hz is legal for use.

It makes no difference which of the two frequencies is used for "mark" and which for "space," but common ham practice is to use the higher of the two frequencies for "mark." In case one station chooses to reverse this, all the other station need do is to reverse the polarity in his receiver—which may be done by merely tuning to the other side of zero beat. The situation is exactly the same as the choice between upper and lower sidebands in SSB operation.

In TTY work, again regardless of the actual code used (and for the rest of our discussion we will assume that the International Five-Unit Code is the one to be used, since it is the one required for ham RTTY by FCC regulations), each character begins with a "start" signal and ends with a "stop" signal. This makes the total character length with a five-unit code actually seven units.

The "start" signal is always a "space" and the "stop" is always a "mark." These two signals establish timing synchronization between the transmitting machine and the receiving machine, and thus make it possible for the intervening code signals to be decoded.

When no character is being transmitted, a steady "mark" signal is sent. The "space" condition produced by the start portion of a character then starts the machine's decoding mechanism. The decoding mechanism sorts out the next five signal conditions to determine what character is being sent, and stops. The "stop" portion of the character simply provides enought time for the decoder to come to rest before another character can be sent.

Normal speed for amateur RTTY equipment is 60 wpm. At this speed, each part of a single character (except for the "stop") lasts for 22 milliseconds. The stop is half again longer, or 31 msec, for a total character duration of 163 msec.

A TTY machine has the appearance of a typewriter; its major parts so far as the operator is concerned are the keyboard and the printer.

When a key on the keyboard is pressed, it sets up in some type of memory device the actual code to be transmitted. This memory device may be either mechanical or electronic. The machines in general use all employ mechanical memory; pressing a key pushes down a notched lever, which then latches in the "down" position. Each key has a different lever, and the notches on each lever correspond to the "space" portions of the character for that key. All these notched levers rest on top of and across another set of five levers, so that when a notched lever is latched down it pushes down any of the second group of levers which do not have notches above them, and leaves up any of the second group which are matched by notches.

This second group of levers operates a set of five contacts, one for each unit of the character code. A motor-driven distributor then wipes a selector brush across the five contacts in turn (the "start" bit of the character is built into the selector mechanism, as is the "stop" bit at the end). If the contact lever for any one unit is up, a "space" is sent when the selector brush wipes across that contact; if the contact lever is down, a "mark" is sent. When the selector brush leaves the last contact, the distributor motor stops and the keyboard is unlatched in preparation for the next character to be sent.

Figure 1 shows the international 5-unit code, without start and stop bits. The

Fig. 1. International 5-Unit Teleprinter Code, required by FCC regulations for use in ham TTY. "x" entries represent "mark" pulses and blank entries represent "space" pulses. See Fig. 2 for timing of signal and start-stop frame which surrounds each character code.

column headed "code bits" shows the code as it would be represented on paper tape; bit 1 is the first one sent after the start bit, and bit 5 is the last sent. The "f" column with its all-"o" entries represents the sprocket feed hole of the punched paper tape, and is *not* a part of the code. An "x" in any entry represents a "mark" condition, and a blank represents a "space."

We have seen how the operator's pressure on any one key is translated into the code pattern to be transmitted to represent that character. The reverse operation, translation of a received code pattern into a character to be printed, is accomplished in much the same way by the printer. However, the printers of the various models of TTY machines are the areas in which the most drastic differences occur.

The explanation of printer action which follows is based on the action of the Teletype Model 12 machine, which is now obsolete. More recent machines operate in substantially different ways, but the model 12's operation serves to explain the basic idea without complicating the description with the complexities of single-magnet operation.

The received signal is applied to the printer as a make-and-break keyed current, with "mark" represented by the presence of current and "space" represented by its absence. In the absence of any received signal, "mark" condition exists and current is flowing through the printer line.

In the printer, this current flows through a latch relay and six selector magnets. So long as current flows through the latch relay, the printer is inactive.

When a character appears, its arrival is indicated by its "start" bit which is a "space" condition. This drops out the latch relay and permits the drive motor to turn the receiving distributor through one revolution.

As the receiving distributor rotates, it connects each of the six selector magnets, in turn, to the signal line at 22 msec intervals. Each selector magnet is either tripped or unaffected by the signal line; if the line condition is "mark" when the selector is connected to the line, the magnet is tripped, and if the line condition is "space" nothing happens.

The first five selector magnets control notched levers, which in the "tripped" position block movement of the key levers which do the actual printing. When all five of these notched levers have been tripped, only *one* key lever can match the notches in all of them. Every other key lever will fail to match a notch in at least one of the code levers.

The sixth selector magnet, which is tripped by the stop bit, permits the printer motor to drive the key-lever mechanism and print the one character which matches. After the printing, the entire mechanism is reset to its initial conditions and the receiving distributor stops, ready to start again which the next start bit arrives.

In later machines, only a single selector magnet is used and its mechanical action is routed to the appropriate points for each bit by a cam which sets up toggle action at the

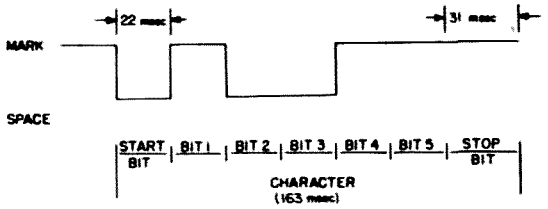

Fig. 2. This waveform shows the appearance of the character "B" as transmitted in the asynchronous serial RTTY code. While code contains only five units, character as sent includes seven. Every character has a "space" start unit, and a "mark" stop unit, in addition to the five units which carry character's meaning. All bits except stop bit are equal length, 22 msec at 60 wpm speed. Stop bit is longer, 31 msec at 60 wpm, to "pad out" to transmission rate and allow time for equipment to stop between characters.

proper time. Some machines do not use key levers; instead, they position a "type box" in front of a hammer so that the selected character will be printed when the hammer strikes.

Not all characters in a TTY machine cause printing. Some, such as "carriage return," "line feed," "letters," and "figures" cause mechanical action in the printer instead.

What we've looked at so far in this examination of RTTY principles is simply the keyboard and printer portions of the TTY machine itself, and applies equally to land-line or wireless operation.

In a land-line setup (called a "local loop" when one is set up in a ham shack, as for test purposes), the keyboard contacts are connected in series with the printer selector magnets and a power supply which frequently is 150V dc at 20 or 60 mA. Pressing a key causes generation of the code character, and the serial code character operates the selector magnets and causes the printer to print. If this all happens in the same machine the result is an electric typewriter; if the keyboard and printer are in different machines, the result is telegraphy without Morse code.

To convert the telegraphy setup to radio, all we need do is find some way to put the "mark" and "space" information on rf rather than on copper wires, and then recover it to drive the printer.

We could simply substitute the keyboard for the hand key in a CW installation, and we would have make-and-break keying. The first amateur work over long distances was done in this manner because no other form of teletype operation was permitted by the FCC. At the receiver, the audio was converted to dc current to drive the selector magnet and that was all it took.

However, make-and-break is no longer used in RTTY. Frequency shift keying (FSK) is almost universally used. The frequency shifted may be the carrier itself (FSK), or an audio frequency modulated upon the carrier (AFSK). FSK is used in the HF bands, but AFSK is used by VHF RTTY enthusiasts because of the difficulty in controlling small shifts at high frequency.

A typical RTTY station is shown in block diagram form in Fig. 3, and compared to an AM station. You can see that the major differences lie in the TTY machine itself, and the circuits connecting it to the transmitter and the receiver.

The transmitter and receiver themselves serve the same purposes as in any other radio communications system. The TTY machine's keyboard generates the proper code for the character to be sent, and the "TTY modulator" converts this code into the proper modulation for the transmitter (frequency shift or FM for FSK, and a shifting audio frequency plus audio modulator circuits for AFSK). The "converter" or "terminal unit"

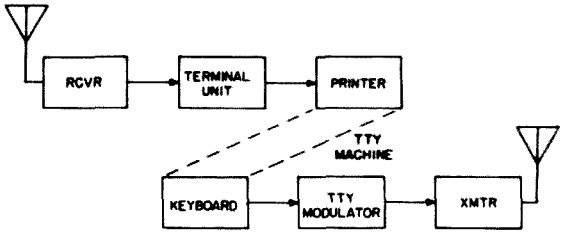

Fig. 3. Block diagram of typical RTTY station. AM station would be same except that speaker would replace terminal unit and printer at receiver output, and microphone would replace keyboard, together with AM or FM modulator or sideband generator replacing TTY modulator, at transmitter input. Major difference is presence of TTY machine, and addition of TU and TTY modulator to interface with it.

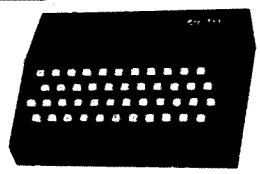
converts the receiver's output into a make-and-break-keyed current suitable for the TTY machine's printer, and the printer then converts this intermittent current flow into a character image on paper.

In the early days, amateur RTTY stations were required to identify themselves by ordinary CW at 10-minute intervals, as well as identifying in the TTY transmission. Rules have since been modified to permit all identification to be done in TTY. The general requirements for identification are the same as for all other amateur stations; both the transmitting station and the receiving station must be identified by call sign.

How is RTTY Transmitted and Received? We've already examined the means by which the operator's pressure on any one key of the keyboard is converted into an electrical code representing the chosen character, and the received electrical code is converted back into a printed representation of the character. But what goes between?

Of course, a radio transmitter and a receiver are used, but the TTY modulator and the converter or terminal unit are the items we're most interested in at this point.

There are almost as many different TTY modulator circuits and terminal unit designs as there are RTTY enthusiasts, but most of these different designs have many items in common.



The major differences, in fact, are brought about by the choice of FSK or AFSK for the modulating technique, and by the choice between FM discrimination and simulated make-and-break for the terminal unit.

If FSK is to be used, the TTY modulator must vary the frequency of the transmitter, and the terminal unit may either generate the driving signal to the printer directly from the receiver's i-f, or indirectly from audio tones produced by the bfo.

If AFSK is to be used, the TTY modulator must first provide a frequency-shifting audio tone and then modulate the transmitter with this tone. Except for the keyed audio oscillator, normal AM transmitter techniques are usually used. The terminal unit for FSK must be of the audio variety.

Since an audio terminal unit can be

Pro-key Kit

Send perfect morse code – from 5 to 50 words per minute. Excellent to build up your code speed – anyone can send practice code.

- Self-completing characters with automatic character spacing.
- Precision kit includes all parts, such as metal case and printed circuit boards, and detailed, illustrated instructions.
- Pre-assembled keyboard with standard typewriter key arrangement and spacing.
- Special characters included, such as AR, SK, BT, period, comma, question mark, slant bar.
- Self-contained battery operated – two standard "D" cells. All solid state.
- Built-in sidetone and speaker, fast acting relay output.

employed for either AFSK or FSK operation, most of the popular designs have been based on this principle. For FSK-only use, however, the straight FM technique can provide the ability to dig much deeper into the crud and noise of a crowded band for solid copy of a weak signal.

Let's examine at least one of each of these types of equipment to see how it functions. Since RTTY in amateur radio began with AFSK, we'll examine an AFSK modulator and terminal unit first, followed by the FSK equipment.

One of the most popular RTTY terminal units ever described was that designed by Marvin Berstein, W2PAT, and originally published in QST. The W2PAT unit provided an introduction to RTTY for a majority of the pioneer RTTY enthusiasts—and more to our point, is an excellent example of a complete AFSK unit. It included both the oscillator to provide a keyed audio tone to a conventional AM transmitter, and the receiving converter to turn received tones into serial character codes to operate the printer.

The AFSK oscillator (Fig. 4) is almost completely conventional. The Hartley circuit provides a stable sine wave output with a minimum of components, but any other oscillator circuit could have been used (and most other circuits were, in one or another of the various designs which followed). The part which makes this circuit different from an ordinary oscillator is the diode switch and frequency-shift capacitor circuit, consisting of resistor R1, diodes D1 and D2, and capacitor C2.

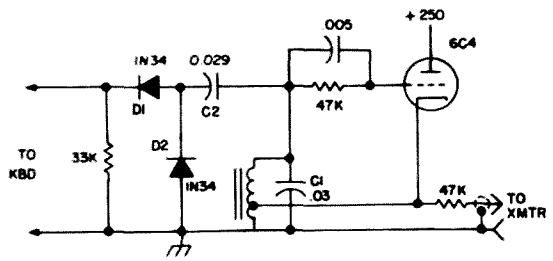

Fig. 4. AFSK oscillator from W2PAT-designed installation. Inductor is TV width coil. Output of this oscillator feeds conventional AM transmitter's mike jack. Capacitor C2's value is varied to adjust for proper shift.

AFSK operators normally indicate "mark" condition with a tone of 2125 Hz, and "space" with a tone of 2975 Hz. The oscillator is tuned, by adjustment of the coil inductance and the value of capacitor C1, to produce output at 2975 Hz when the keying circuit is open-circuited.

When the keying circuit is closed, R1 is shorted out. This permits diodes D1 and D2 to switch capacitor C2 into the circuit in parallel with C1, thus lowering the output frequency. The value of C2 is adjusted by trial and error until the output frequency is 2125 Hz.

Operation of this diode switch may appear a trifle mysterious at first, since no external power is supplied to turn the diodes either "on" or "off." What actually happens is that the diodes rob enough power from the oscillator tank circuit to develop their own switching voltages. D2 conducts for half of each cycle regardless of the keyboard contact position; during the half-cycle that D2 is "off,' D1 attempts to conduct. The current flow through D1, however, must flow through R1, and a voltage is developed at the "hot" end of R1 which tends to keep C2 isolated from ground.

When the keyboard contacts are closed, R1 is no longer in the circuit and the current flow is direct to ground on both halves of the audio cycle (through D2 on one half and D1 on the other). The diodes now act just like a closed switch, and cut C2 into the circuit.

Because of the diodes, the keyboard contacts handle only a small amount of dc rather than being required to switch ac or high-current dc. This minimizes rf interference to the receiver—in RTTY this is an important point, because the printing action on the machine normally results from the signals which have gone all the way through the system, rather than on any direct connection between keyboard and printer.

The receiving-converter portion of the W2PAT terminal unit (Fig. 5) is not so familiar-looking as the oscillator. It consists of a double-diode limiter followed by a two-stage amplifier which is operated in an over-driven condition to serve an additional limiting function. Output of the active

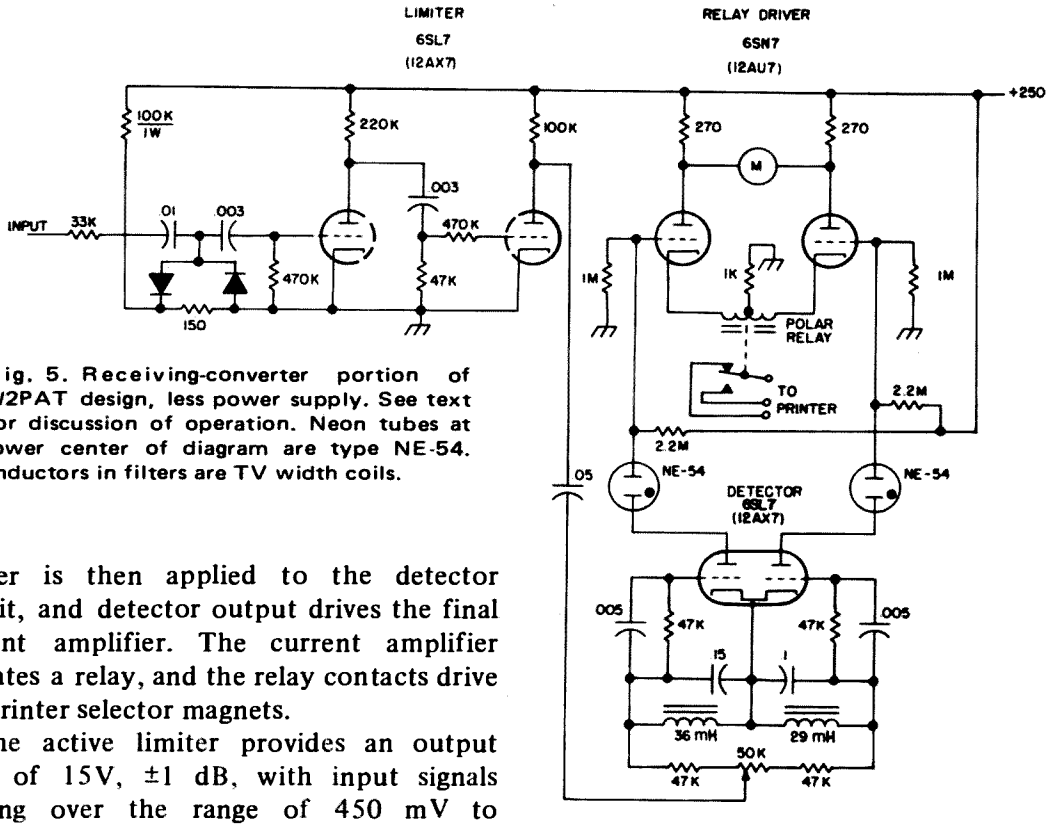

Fig. 5. Receiving-converter portion of W2PAT design, less power supply. See text for discussion of operation. Neon tubes at lower center of diagram are type NE-54. Inductors in filters are TV width coils.

limiter is then applied to the detector circuit, and detector output drives the final current amplifier. The current amplifier operates a relay, and the relay contacts drive the printer selector magnets.

The active limiter provides an output level of 15V, ±1 dB, with input signals varying over the range of 450 mV to more than 30V. This 15V signal is applied to the detector, which actually consists of two separate grid-leak detectors, each tuned to a separate audio frequency. One half of the circuit is tuned to the mark frequency and the other half to the space frequency. Since only one of these two frequencies is present at any one time, one side of the circuit is always drawing more current than is the other side, and this swing of the heavy current flow from one side to the other in the detector stage corresponds to the mark-or-space condition of the TTY signal.

The plates of the two detector circuits are coupled through neon bulbs to the grids of another dual-triode tube. The neon bulbs act as threshold devices. Until firing voltage for the neon is reached, grid voltage on the final tube remains zero. When current flow in one side of the detector drops due to lack of signal at the associated frequency, the plate voltage rises, and when the neon fires the grid of that side of the current amplifier tube goes positive. This makes that half of the final tube draw heavy current, thus pulling the polar relay to the corresponding position.

When the AFSK signal's frequency returns to that to which the detector is tuned, the detector stage current increases and plate voltage drops. When plate voltage falls below about 55V, the neon goes out and the grid of that side of the current amplifier returns to ground voltage. At the same time, plate voltage in the other half of the detector was rising and turning on the other side of the current amplifier, thus reversing current through the output relay and driving it to its other position.

The milliammeter connected between the plates of the current amplifier stage is a tuning indicator. When tuned to a TTY signal which has a mark-to-space ratio of 1:1 (as much time spent in mark condition as in space condition), the meter will indicate zero average current. This is because the meter movement is unable to follow the rapid fluctuations of current, and if the mark-to-space ratio is 1:1, the *average* current fluctuation will be zero.

Another way to provide such a test signal is simply to key an AFSK oscillator with a square wave or an electronic key set for all dits; the RYRYRY sequence is traditional

but the keyed oscillator is more reliable since it does not depend upon the keyboard being in proper adjustment.

Many other AFSK units have been described and put into use since the W2PAT unit made its appearance; a large portion of those in use today use transistors rather than tubes. The basic principles of all are similar, however, in that the two audio tones are split into separate channels and the TTY code is recovered by detection of both channels. The limiter is also a usual feature since it provides the ability to operate with a minimum of critical receiver adjustment between stations.

FSK equipment is similar in many ways to AFSK gear, but differs in some important respects. The modulator consists of a circuit to switch capacitance across the tuning circuit of the regular transmitter vfo (crystal oscillators are difficult to get enough shift on). Such a circuit is shown in **Fig. 6**. Like the AFSK oscillator, a diode switch is used, but this diode switch is powered by voltage stolen from the transmitter B+ supply. The function of the switch is to connect the added capacitor C1 across the tuning capacitor when the keyboard contacts are open, and to remove it when the contacts are closed. This makes "mark" the lower frequency and "space" the higher one. Note that this is the exact reverse of AFSK practice.

The frequency shift is usually 850 Hz, but any shift less than 900 Hz can be used legally. The variable resistor controls the amount of shift, by varying the effect of the added capacitor. When changing from one band to another, this resistor normally must be adjusted to take into account the frequency multiplication introduced by most transmitters at the higher bands.

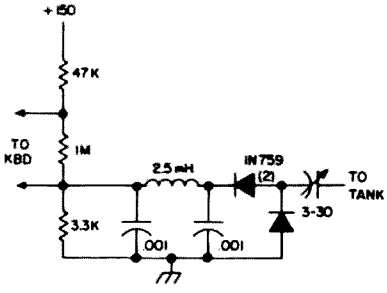

Fig. 6. Typical switching circuit for direct FSK. 3-30 pf trimmer is coarse adjustment on maximum amount of shift attainable; 1 meg pot is operating adjustment. All components to right of rf choke should be mounted as close as possible to vfo tank circuit, and be made mechanically solid to avoid frequency instability. Components to left of rf choke may be located anywhere. Keyboard contacts must be insulated from ground for use in this circuit.

Many RTTY enthusiasts receive FSK by using AFSK terminal units, converting the FSK signal to AFSK by turning on the receiver bfo and tuning carefully.

However, an FSK signal *is* an FM signal, and an FM detector operating at the receiver's intermediate frequency can in many cases give superior performance. The FM detector can be any of the conventional FM detector circuits—discriminator, ratio detector, or pulse counter. Its major point of difference from audio AM detectors is that it must respond to low-frequency signals, since the 22 msec duration of a TTY bit is about 23 Hz in sine-wave terms.

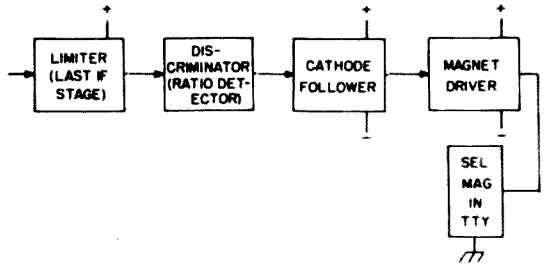

Fig. 7. Block diagram of typical direct-FSK or i-f RTTY terminal unit. Limiter and FM detector are completely conventional, but from FM detector output all the way through to TTY printer selector magnets dc coupling is employed.

Such a direct-FSK terminal unit is shown in block-diagram form in **Fig. 7**. Both the limiter and discriminator stages are completely conventional. The cathode follower between the discriminator and the driver stage permits direct coupling for good low-frequency response.

The driver stage is a switching circuit, so hooked up that a "mark" signal produces current flow through the output terminals and a "space" signal stops the flow of current. Both positive and negative power supplies are used so that the output terminals will be at approximately ground potential to minimize shock hazards.

Filtering Devices

How Do Filters Operate? The temptation is always present to answer a question phrased "How do . . . " with "Very well, thank you!" and let it go at that—but this would hardly be fair, since we asked the question ourselves in the first place. Besides, many filters operate only poorly, if at all, because until very recently filter design was essentially a cut-and-try proposition. Classical theory upon which the design was based called for physically impossible components in the filter, and substitution of realizable items led to inaccuracies in the design. This situation, fortunately, has now been cured, and we'll look at "how" a little later.

The purpose of a filter is to separate ac signals. In general, a filter must fall into one of four categories—"highpass," "lowpass," "bandpass," or "bandstop." A highpass filter passes all signals higher in frequency than its cutoff frequency and stops all lower-frequency signals. A lowpass filter does the reverse. A bandpass filter passes all signals between its lower and upper cutoff frequencies and blocks signals either higher or lower in frequency than its passband limits, and a bandstop filter blocks passage of frequencies within its band while permitting all others to pass.

These four categories of filters are based upon the action performed by the filter. Any filter, though, must operate at some specific frequency or frequencies. The frequencies involved may be subsonic, audio, intermediate, or radio frequencies. The design of any specific filter depends upon both the action to be performed, and the operating frequencies involved. Components employed in the filter, and the apparent principle of operation, may vary widely with the action and the frequency.

However, when we get right down to the basics we find that all filters operate on the same basic principles despite apparent differences. These apparent differences are best illustrated by some examples of various filters: The filter portion of a power supply is a lowpass filter operating in the subsonic frequency range, while the TVI filter on a transmitter output is usually a lowpass filter operating in the rf region. A TVI filter of the sort connected to affected TV receivers is a

highpass filter operating in the rf range. The mechanical filter used in SSB work is a bandpass filter operating at the intermediate frequency, and so are the crystal lattice filters also used in SSB. For that matter, an i-f transformer is a bandpass filter, as is any resonant circuit. RTTY filters are also bandpass designs, but operate in the af region.

All filters are based on the frequency-dependent properties of reactances (even the mechanical filter makes use of the mechanical equivalent of electrical reactance). Capacitive reactance X_C decreases as signal frequency f rises, while inductive reactance X_l goes up with increasing frequency. By proper choice of the type and amount of reactance any desired filter action can be obtained (within reasonable limits, as we shall see a little later).

To illustrate the principle, let's examine a single stage, subsonic, lowpass filter typical of those used in many power-supply designs. The schematic appears in Fig. 8.

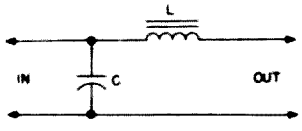

Fig. 8. Single section lowpass filter. Values of L and C determine cutoff frequency of filter section.

At frequencies far below the "cutoff" frequency of this stage, the inductor presents a very low value of X_l and the capacitor has a very high value of X_C. Both reactances are so extreme that they may be ignored, and the filter becomes in effect a straight piece of wire with no effect on the signal.

At frequencies far above cutoff, the situation reverses. The inductor's reactance is very great and the capacitor's reactance is very low. The filter becomes in effect a dead short, with no path from input to output, and the signal is blocked.

The "cutoff" frequency of this type of filter is defined as being that frequency at which X_l equals X_C. At this frequency, since reactance is equal in both directions, half the signal current flows to ground and the other half flows through the filter. The signal is neither passed without loss nor blocked completely.

At frequencies near cutoff, the situation is similar to that at the cutoff frequency. Signals slightly below cutoff frequency will be slightly attenuated, but the lower the frequency becomes the more of the signal goes through and the less of the signal is bypassed to ground. Signals slightly above cutoff are still partially passed, but as the frequency rises less and less of the signal makes it through the filter. There is no such thing as a perfect filter which passes everything below cutoff and blocks all above.

Filter performance can be improved, though, by adding more stages. If two of these stages are cascaded one after the other, then at cutoff frequency the first stage will block half the signal and permit half to pass. The second stage will block half of the half that passes through the first, and permit only 1/4 of the original signal to get through the composite filter.

Adding a third such stage will reduce the output signal level to 1/8 that at the input. A fourth stage will halve this, to 1/16 the original level. Five stages will cut the output to 1/32, and so forth.

When extra stages are added, though, the definition of "cutoff frequency" must be changed. Each stage's cutoff frequency is defined exactly as before, but the cutoff frequency of the filter as a composite unit becomes lower with each added stage, because for any filter the definition of "cutoff frequency" most generally used is that frequency at which the filter reduces output signal level to half the level present at the input.

Our two-stage filter in the example would have a composite cutoff frequency only 0.7071 times as great as the single-stage filter; the three-stage filters cutoff would be at a frequency half that of the single stage filter. These ratios apply only to the simple design shown in Fig. 8; more complex filter designs have different rates of cutoff-frequency change, and in general a filter is designed for specified performance rather than being built up of some arbitrary number of identical stages.

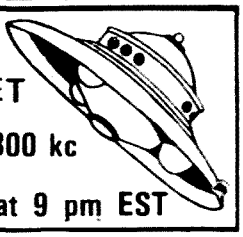
We have just examined the basic principles as applied to a simple lowpass filter. A highpass filter works the same, except that the inductor and capacitor are inter-

changed so that signals *above* cutoff are passed and those below cutoff are blocked rather than vice versa as in the lowpass circuit.

To get a bandpass filter, we could simply build a highpass filter with cutoff set at the lower band limit, and follow it by a lowpass filter with cutoff set at the upper band limit. For extremely wide passbands this is sometimes done. One example is the 300-3000 Hz band frequently used for voice communication; this is too wide a bandpass for simple bandpass filters to handle, and the economical way out of the problem is to first trim off one limit and then trim the other.

For narrow passbands, though, something more like a tuned circuit is generally used.

Not all filter stages are as simple as that shown in Fig. 8. Tuned circuits may be included instead of simple reactances, and the resonance frequencies may be far different from the intended cutoff frequency in order to modify filter performance. The variations possible in filter design on this basis gave rise to the "image-parameter" theory of filter design, which ruled the design of most filters for more than 30 years and even today is still widely used.



However, reactances which satisfy the demands of image-parameter theory are physically impossible, because the theory demands that the resistive portion of the circuit be zero at cutoff frequency, changing in the same manner as a capacitive reactance below cutoff, and changing in the same manner as an inductive reactance above cutoff, while actual resistances are independent of frequency.

Because many filter requirements are only approximate, this design method has been able to give circuits acceptable for most purposes. When more accurate designs were required, cut-and-try fitting of values was the normal course.

Any filter, though, is a network of components connected together, and any such electrical network must obey certain basic rules known to engineers as "Kirchoff's Laws." These state, in essence, that as much current must flow into any point as flows out and vice versa. We might say simply that the current must go somewhere—it can't just disappear!

These rules can be written as a series of algebraic equations, and to apply them to the analysis of any arbitrary network we must do just that. The laws state that all the current must be accounted for, and the equations do the accounting.

Since a filter is a network, the filter can be described by a suitable series of equations. The filter designer can then solve the equations to find the network parameters which will produce optimum performance in some desired respect. Performance will be poorer than optimum in some other respects when this is done, since all design represents compromises, but the "modern network theory" design technique for filters permits the designer to choose the performance he wants where the "image parameter" approach permitted only one or two parameters to be designed for.

We won't go any deeper than this into modern network theory, since it *is* a mathematical technique and one of our guiding principles in this course is to stay away from all mathematics which we can avoid. If you're interested, the fourth edition of "Reference Data for Radio Engineers" (and presumably the just-published fifth edition as well) contains 47 pages (pages 189 through 235) describing the technique.

We'll merely note that the modern-network-theory design approach permits a number of different filter response curves, and the resulting different filters are usually identified by names associated with the shapes of these curves. The two most widely known are the Chebishev (also spelled Tshebysheff, Chevishef, and Tshebishev) and the Butterworth filters. The Chebishev design provides the sharpest possible rate of cutoff at the cost of permitting ripple in the passband, while the Butterworth design maintains passband response flat at the cost of moderate phase shift and less steep cutoff rates.

It may seem a bit odd for us to declare that all filters are based upon reactance when crystal lattice filters composed of several quartz crystals are so widely used, but electrically the crystal is just a very-high-Q tuned circuit and contains both X_l and X_c. When used in a filter, the X_l and X_c provide the filtering action. We'll look at this in more detail in a subsequent section. First, let's see how filter performance is rated.

How Is Filter Performance Rated? Filter performance is rated according to several factors, and the factors involved vary to some degree with the type of filter in question. One factor present in the rating of every filter is its "attenuation"; this is a measure of the signal level at the output side of the filter compared to the level at the input side.

Every filter possesses some definite value of attenuation at every frequency. A low-pass filter has attenuation both below and above its cutoff frequency, as do highpass filters, bandpass, and bandstop varieties. Attenuation is usually expressed in dB.

If the output level at some specified frequency is the same as the input level, the attenuation at that frequency is $\emptyset$ dB. If the output level is zero for any value of input level (a condition theoretically possible but not attainable in practice because of stray coupling around the filter), the attenuation at that frequency is infinite.

A plot of attenuation versus frequency gives the "response curve" of the filter. Fig. 9 shows typical response curves for the four categories of filters.

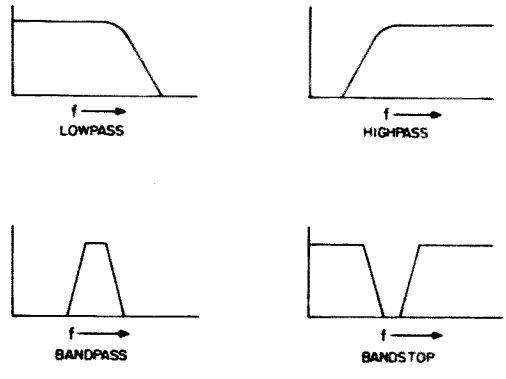

Fig. 9. Typical response curves of the four major categories of filters. These response curves are idealized; actual response curves have more rounded corners and never quite reach the zero-output point.

Another factor in common for all filters is "cutoff frequency," but now that we have established the meaning of "attenuation" we are in position to define cutoff frequency

more accurately than we did earlier. The cutoff frequency for a given attenuation may be specified as the frequency at which the filter has that value of attenuation. Thus the 3 dB cutoff frequency for a lowpass filter will be lower than the 6 dB cutoff frequency. The definition we developed earlier—that frequency at which output level is half of input level—actually defines the 6 dB cutoff frequency of any filter.

A glance at Fig. 9 will show that both bandpass and bandstop filters have not one but two cutoff frequencies, since for any specified value of attenuation there is a frequency below the filter's center frequency which has that attenuation, and another frequency above center frequency. The two cutoff frequencies of band filters are designated as "upper" and "lower" cutoff frequencies.

Sometimes filters are compared according to their "slope" or "cutoff rate." This is a relative term referring to the rate at which attenuation changes with frequency. Engineers speak of slope or cutoff rate in units of "dB per octave"; this means the number of dB change in attenuation when the frequency is doubled. A single reactance has a slope of 6 dB per octave; that is, if frequency is doubled the reactance is either doubled or halved, and the resulting ratio is 6 dB (2:1 voltage or current, and 4:1 power ratio). Filters with two reactances usually have slopes of 12 dB per octave, with the slope increasing 6 dB per octave for each added reactance in the filter. This is not an airtight law, however; many filters have slopes which do not follow this rule, and almost no filter follows this rule at frequencies near the cutoff point or within the passband.

All filters have a "bandwidth," but the term has different meanings depending on whether the filter is (1) lowpass or highpass, or (2) bandpass or bandstop. For lowpass or highpass filters, the bandwidth for a specified attenuation is the actual frequency at which the filter has that attenuation. The "width" means the number of cycles from zero frequency to the frequency in question. Thus the bandwidth for 3 dB attenuation of a lowpass filter with a 3 dB cutoff frequency of 100 Hz is 100 Hz.

For symmetrical bandpass or bandstop filters, the bandwidth is the difference (in hertz) between the two cutoff points for the specified attenuation. A bandpass filter with an upper 3 dB cutoff frequency of 10 kHz and a lower 3 dB cutoff frequency of 8 kHz would have a 3 dB bandwidth of 10-8 or 2 kHz.

Bandwidth is always specified for a definite attenuation level, because it is defined in terms of cutoff frequencies, which are themselves defined only by attenuation level. Unless the attenuation level is specified, any use of "bandwidth" as a rating factor is meaningless.

For bandpass filters in particular, the bandwidth is one of the primary measurements—but it is by no means the only one. Consider two different bandpass filters, both having 6 dB bandwidths of 3000 Hz. The first, however, is a very simple filter with only a few reactances and consequently has a very slow rate of cutoff, while the other is a complex Chebishev design with steepest possible cutoff rate. The first filter may have a 60 dB bandwidth of 30 kHz and the 60 dB bandwidth of the second might be as narrow as 6 kHz. (**Fig. 10**).

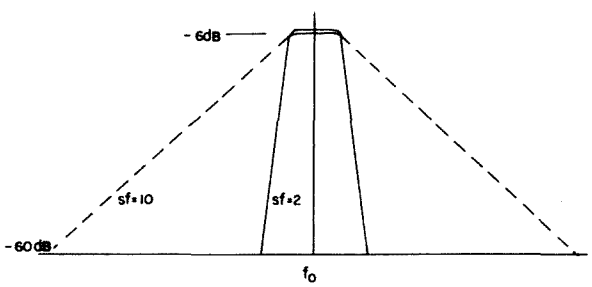

Fig. 10. Significance of "shape factor" is shown here. Both filters whose response curves are illustrated have 6 dB bandwidths of 3 kHz. That in solid lines has a 60 dB bandwidth of only 6 kHz, while that in dotted lines has 60 dB bandwidth of 30 kHz. Difference in effective passband is clearly evident.

Obviously, the second of these filters will do a far better job of trimming applied signals down to its passband.

The term "shape factor" is used to describe the property we have just compared; the "shape" referred to is that of the

filter's response curve. A perfect bandpass filter would have absolutely vertical sides to its response curve, with zero attenuation between the two cutoff frequencies and infinite attenuation outside that range. Actual bandpass filters have response curves which vary from a barely perceptible hump up to a steep-sided curve very much like that of the perfect filter.

The "shape factor" of a bandpass filter is the ratio between its bandwidths at two different attenuation levels. In ham practice, the 6 dB and 60 dB bandwidths are the ones most often used. The shape factor ratio is always obtained by dividing the larger bandwidth by the smaller, so that it is always greater than 1. A perfect filter with vertical sides to the response curve would have the same bandwidth at all attenuation levels, and so would have a shape factor of 1. Practical filters always have greater bandwidth at high attenuation levels than they do at the lower-attenuation points, and so their shape factors are always greater than 1. If the 6 dB bandwidth of a filter is 1.5 kHz and the 60 dB bandwidth is 3.0 kHz, the 6-60 dB shape factor of that filter is 3.0/1.5 or 2; this represents excellent performance. Many bandpass filters in use today have shape factors as great as 10. The shape factor of a single tuned circuit when used as a bandpass filter may be as great as 100.

How Are RF Bandpass Filters Constructed? One of the requirements for any receiver intended to operate in today's crowded rf spectrum is that it have extreme selectivity. Ideally, it should be able to tune in either sideband of an AM signal while rejecting both the carrier and the other sideband. This is known as selectable sideband capability, and marks an extremely selective receiver.

Almost universally, such selectivity is achieved by use of bandpass filters operating in the rf or i-f range. Since normal i-f's are actually radio frequencies, we'll lump these filters together for our discussion.

RF bandpass filters capable of providing shape factors smaller than about 10 are most often one of two major types—mechanical filters and crystal filters. We won't go into details of the mechanical filters here, since they have little to do with electrical and electronic phenomena.

Crystal filters themselves divide into two major groups. One of them uses only a single crystal, to provide a very narrow response curve with relatively poor shape factor. This type, which was standard equipment on older communications receivers, provides excellent results on CW but is not so hot for reception of voice signals. The second group, which used two or more crystals, provides greater bandwidth than the first, with smaller shape factor. It is widely used in SSB operation, since the shape of its response curve matches the requirements for voice communication.

The single-crystal type of filter is normally known simply as a "crystal filter," while those using two or more crystals are generally called "crystal lattice filters." Technically, a lattice filter must use four crystals, or multiples of four, but an electrically equivalent circuit called a "half-lattice" requires only two crystals, and is possibly the most popular type of lattice filter in use now.

Let's examine both groups of filters separately, taking the older single-crystal filter first. The schematic of a typical single-crystal filter circuit appears in Fig. 11. The driving transformer splits the signal into a pair of signals, equal in strength but opposite in phase. One of these two signals is applied to the quartz crystal while the other is applied to a "phasing condenser" which is simply a variable capacitor. The two signals are then put back together at the input to an amplifier stage.

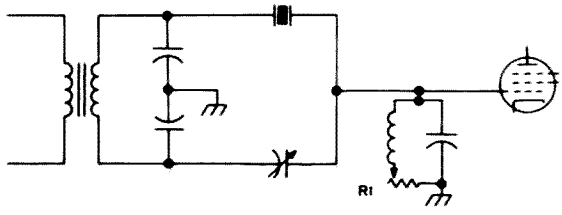

Fig. 11. Typical single-crystal i-f filter of type used for CW reception. Adjustment of capacitor tunes out parallel resonance of crystal to give symmetrical passband, or can move parallel resonance to either side of series resonance to insert a "rejection notch" anywhere within passband except at series-resonant frequency itself.

The quartz crystal is equivalent to a very high Q resonant circuit; it has both series and parallel resonances. At the frequency of series resonance, it is an extremely low resistance, while at the frequency of parallel resonance it is an extremely high resistance. In the absence of the phasing condenser, this circuit would permit signals at series resonance to pass through almost unchanged, while attenuating signals at other frequencies greatly and providing almost infinite attenuation at parallel resonance.

The phasing condenser, however, provides an alternate path for the signal around the crystal. When the phasing condenser is adjusted so that its capacitance exactly balances the parallel capacitance of the crystal and its holder, the parallel resonance of the crystal is eliminated and the filter's response curve becomes a single sharp peak. The rejection notch at parallel resonance is eliminated.

When the phasing condenser is adjusted for either more or less capacitance than that required to balance the crystal, the effect is to tune the parallel resonance of the crystal to some definite frequency. This introduces the rejection notch, and makes it possible to move the rejection notch relative to the passband peak, permitting a single interfering frequency to be "notched out" of the signal.

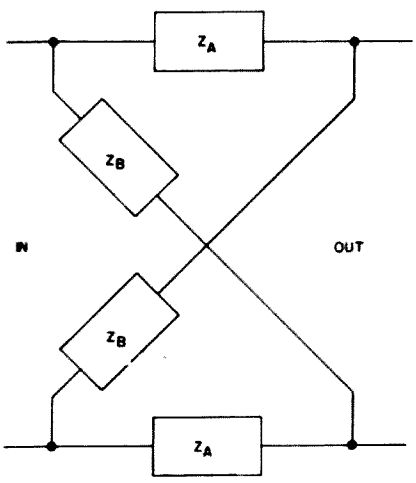

Fig. 12. Full-lattice filter arrangement in block diagram form. Each block represents an impedance having characteristics of the circuit shown in Fig. 13. When interconnected as shown here, passbands of "A" and "B" sections interact to provide a flat-topped passband with excellent shape factor.

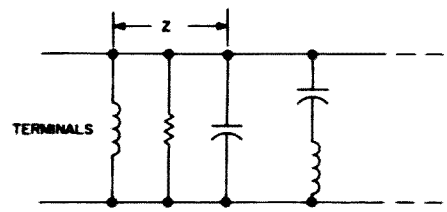

Fig. 13. Equivalent circuit of each impedance in full lattice filter. Parallel-resonant circuit at left represents parallel resonance composed of crystal and stray circuit capacitance, together with loading resistances. Series-resonant circuit at right (which may be extended indefinitely as indicated by dotted lines) represents series resonances of each crystal in each leg. Impedances "A" and "B" are parallel resonant at lower cutoff frequency. Series resonances introduce "infinite rejection" notches just outside passband to sharpen skirts of filter.

Adjustment of resistance R1 modifies the loading imposed on the filter, and varies the effective bandwidth. The 6 dB bandwidth of such a filter circuit can be varied from about 50 Hz when R1 is extremely large, out to greater than 6 kHz when R1 is very small.

The multiple-crystal filter designs are based on the lattice structure shown in Fig. 12. Each section of this lattice structure consists of one or more crystals, and provides the equivalent of the circuit shown in Fig. 13. Much of this circuitry can be eliminated by replacing the lattice with its equivalent shown in Fig. 14; the lattice arms themselves now require only single quartz crystals using their series resonances.

Characteristics of such a filter are determined primarily by the number of crystals used, and the degree to which they are matched. Those crystals marked A and those marked B must not tune to the same frequency. In fact, the spacing between the series resonant frequency of crystals A and that of crystals B is the major factor determining the filter's bandwidth.

Design of such a filter is done by modern network theory, usually using the Chebishev techniques, and is too complex for us to explore here. In general, the bandwidth determines the spacing between resonant

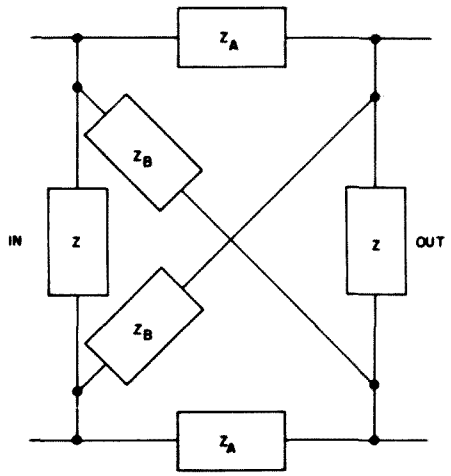

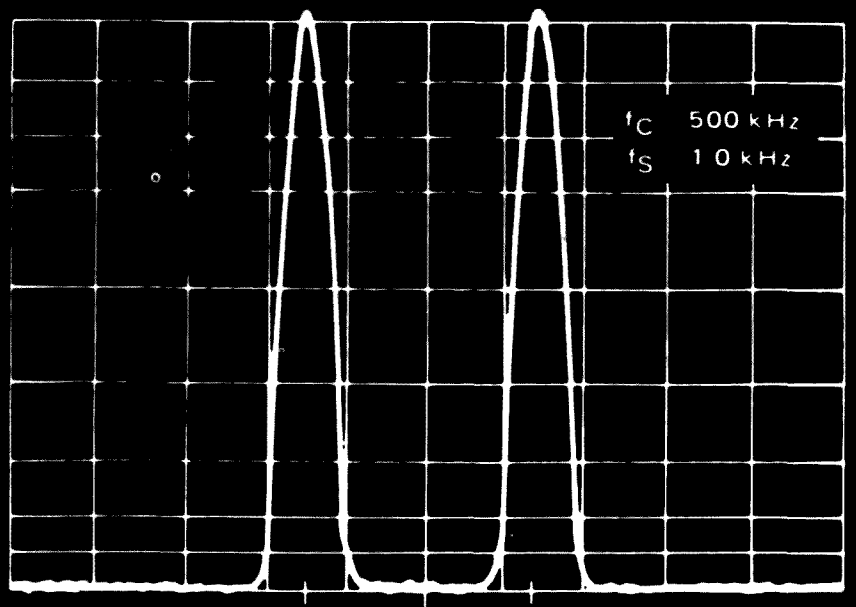

Fig. 14. Load resistances and stray circuit capacitance of full lattice filter can be moved to input and output terminals as indicated here. This circuit is electrically the same as that of Fig. 12. Each "A" and "B" block is still the circuit of Fig. 13, which may in practice consist of a single crystal for each block.

frequencies of the two groups of crystals. Within each group, characteristics of each crystal must match as closely as possible (many commercial crystal filters use a single crystal with multiple electrodes on it, each pair of such electrodes serving as a "different" crystal in the lattice, to assure identical characteristics). So long as the filter's center frequency is not greater than about 250 times its desired bandwidth, good shape factor can be attained easily. That is, for a "phone" bandwidth of 3 kHz, any center frequency up to 750 kHz could be employed. In fact, successful lattice filters with center frequencies as high as 10 MHz and bandwidths as small as 2 kHz have been built, but design is more critical.

NEW LINEAR ICs FOR THE HAM

. . . . . THEY'RE NEW, HOT, AND CHEAP !

Hams have been using integrated circuits almost since they were first introduced commercially at reasonable prices. The earliest ham uses were keyers and frequency standards using digital ICs. ICs are so useful in these applications that it is difficult to imagine anyone building a keyer out of discrete semiconductors, or (perish the thought) vacuum tubes, anymore. ICs with their low-voltage operation and great circuit simplification make even complex projects relatively easy and inexpensive to build.

The resistor-transistor logic (RTL) family (the Motorola MC700P series and the Fairchild μL900 series) has been the most popular type of integrated circuits for experimenters. Both are packaged in inexpensive plastic cases, and though the Motorola devices have won out in most uses because they are lower in cost and furnish more functions per package, many of the Fairchild parts have also been used.

There has been relatively little use by hams of linear integrated circuits up to now, though a few of the audio power amplifiers that have been introduced by RCA, Motorola, and GE in the past few years have seen some use. This would be surprising at first glance because most ham applications are linear or analog ones, rather than digital. However, the digital circuits were much cheaper and more widely available, hence attracted more attention in the past. Recently, however, many different types of linear integrated circuits have become very attractive for ham use. They are now available at reasonable prices for many applications.

605

Many of the new linear integrated circuits that are of particular interest to hams have been designed for consumer use. This assures that they will have reasonable prices; expensive ICs can find little use in consumer equipment. Table I lists many of the linear integrated circuits that are now available. They include voltage regulators, audio amplifiers of various types, i-f amplifiers, a unique new circuit called the balanced modulator, and operational amplifiers. Any one of these ICs can replace many discrete devices, and in many cases can provide much higher performance than any practical combination of discrete devices could. They also are relatively inexpensive, ranging in price from $1.50 for an i-f amplifier to $7.15 for the balanced modulator/demodulator, a recently

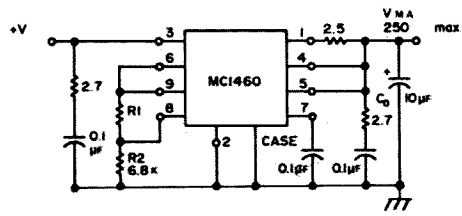

Fig. 1. High-performance IC regulator using the MC1460. The input voltage, V_{IN} must be at least 3V greater than the output. Maximum input for the MC1460 is 20V. The MC1460 is good for 35V input. An etched circuit board is recommended for construction. Use VHF techniques.

introduced part. All of the parts described are manufactured by Motorola, and are readily available from the many Motorola distributors, including Allied Radio and Newark.

Voltage Regulators

One of the most dramatic examples of the simplification that a linear integrated circuit can provide in a circuit is the voltage regulator.

The MC1460 series of voltage regulators can provide up to 600 mA of output current at over 30V with no external transistors or other semiconductors. Only a few small resistors and capacitors are required to produce a complete regulator with excellent characteristics.

Four members of the MC1460 family are of particular interest to hams. The MC1460 has a maximum input of 20V and the MC1461, a maximum input of 35V. The "G" versions (in a package very much like the TO-66 case used for silicon power transistors except that it has 9 pins instead of 2) can handle 600 mA when it's mounted on an adequate heatsink. Four similar regulators are available in the MC1560 series with a full temperature range which makes them more suitable for military use. They cost significantly more.

The MC1460 series has a typical low output impedance of only 0.025-0.035Ω at frequencies up to 100 kHz. Regulation for changes in input voltage is typically only 0.003% per volt, a remarkably low figure. The MC1460 can put out voltages as low as 2.5V and as high as 17V. The output voltage must always be at least 3V less than the input voltage for the regulator to work properly. Another interesting feature of the MC1460 series is its short-circuit protection. The regulator will not be damaged by a continuous short circuit.

A basic MC1460 circuit is shown in **Fig. 1**. It can put out a maximum of 250 mA. It uses only a few small 0.25W resistors and capacitors. In the circuit, resistor R1 is selected to give the desired output voltage. A potentiometer can be used for a variable output, but this circuit is really more suitable for a fixed rather than a variable voltage.

The regulator as shown will limit output current to 250 mA. If you try to draw more current than this, the regulator will automatically reduce the output voltage. This short-circuit current is determined by the 2.5Ω resistor connected to pin 1. This resistor can be changed to get other maximum output currents.

The MC1460G, which is in the TO-5 package, will require a heatsink for currents near its maximum, and the MC1460 will likewise require a heatsink for high current values. Probably the most practical type of heatsink for the R package is one with a hole large enough for all 9 pins to pass through without shorting. This is much more practical than trying to drill holes for each one of the nine pins. A socket is available for the MC1460R, but it is hard to find and relatively expensive.

One word of caution if you are used to building dc power supplies: The transistors used in the MC1460 are very high-quality VHF devices; hence, the circuit must be treated properly or it's likely to oscillate at very high frequencies. You'll notice in **Fig. 1** that a number of capacitors and resistors are included for high-frequency suppression to prevent the circuit from oscillating. You should use an etched circuit board for

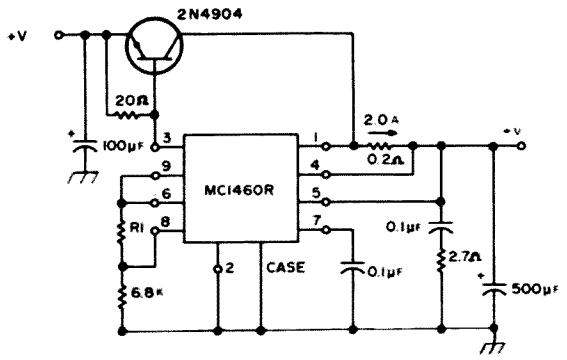

Fig. 2. IC voltage regulator with 2A capability using external series-pass power transistor.

constructing this regulator so that you can get very short leads and a good ground.* It is not practical to go into all the fine points of the circuit; however, the data sheet for the MC1460 series is comprehensive and provides complete information on using the device.

Two other circuits using members of the regulator family are shown in Figs. 2 and 3. Figure 2 is a 2A voltage regulator using an external PNP series-pass power transistor. A similar technique can be used to provide up to 10A for applications requiring this amount of current. More information is given in the data sheet.

Figure 3 is a laboratory power supply with an output adjustable from 0 to 25V. It will provide up to 400 mA. This circuit, unlike many power supplies, can go all the way down to zero volts. It is also interesting because of the extreme simplicity of the circuit. It would be interesting to compare Fig. 3 with a typical regulated power supply using discrete devices. The discrete version would be far more complex and expensive, and yet would not provide the same performance.

The Motorola MC1469 is a regulator similar to the 1460, but even less expensive, and designed for less exacting uses. No circuits are included for this device because they were not available at the time this article was prepared. However, the data sheet on the devices will give considerable information.

Another voltage regulator of particular interest is the MC1466, which is designed for use with external transistors. It can be used to regulate voltages as high as 1000V or even higher. In this application, the regulator is floating, but it can be protected against shorts even though the external pass transistor used with it may not be able to stand this high voltage if the output is shorted. More practically, or perhaps of more interest, the 1466 can be used to provide very high current at lower voltages, or provide medium current with voltages in the 100 to

*A board is available for $1.50 from Project Supply Company, PO Box 555, Tempe AZ 85281.

BACK ISSUE GUNSMOKE !

30, count 'em 30, stupendous tremendous (more handbooks than magazines) fascinating enormous devastating incredibly enervating back issues of 73.....

ONLY $5.00
postpaid worldwide

Yes...yes...yes...here is a golden opportunity to blow your mind on 30 back issues of 73. You send us $5 in negotiable securities, cash or check and we will send you an unbelievable miscellany of thirty different (all different) back issues, all from the 1960-1966 era. These are all rare collectors items. Every one could likely be worth a fortune to you. Who knows, you might even find a rare January 1961 in this pile! We don't even know what is in these packages. To keep costs down we have had these magazines packed into sloppy bundles by the Chimps from Benson's Wild Animal Farm (nearby). Watch out for banana skins. —If you want specific issues of 73 they are available at the low low (high) price of $1 each. Unless we don't have them, In which case the price is higher. —How about sending a bundle to a DX friend? Back issues of 73 are worth their weight in unicorn dung in most countries. —Money received without a shipping address will be used for beer.

73 Magazine Peterborough NH 03458

200V range. This would be useful, for example, as a screen supply for a transmitting tube. Other voltage regulator ICs are available; most are made for use with external transistors for currents of more than about 10 mA.

All in all, the new IC voltage regulators make it very easy to design and build a power supply to provide almost any current or voltage with very little work, and assurance that the circuit will work properly without needing any adjustments. The day of the discrete semiconductor regulator seems to be rapidly approaching its end.

Audio Amplifiers

Many of the new inexpensive linear ICs are audio amplifiers. Some are designed for low-level use, others for moderately high power; that is, a watt or more. Starting at the low end of the price and complexity scale is the MFC4010, a wideband amplifier that can provide up to 60 dB of gain at 1 MHz, so it's suitable not only for audio, but also i-f applications.

The MFC4010 is one of the first of a new breed of consumer ICs. It has only four pins; the package is a small version of the dual in-line package that has become so popular. The four pins are positive voltage, ground, and the input and the output. That's all; no complex compensation is needed as has been required in the past for most ICs.

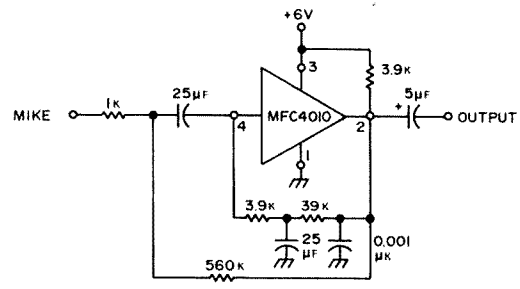

Fig. 4. High-gain audio amplifier using MFC4010 wideband amplifier.

The MFC4010 is especially useful as a microphone amplifier or as a general-purpose 455 kHz i-f amplifier. A typical circuit using this device is shown in Fig. 4. It operates from 6V; it's an audio amplifier for a microphone, and as you can see, very few external components are required to provide high gain. The MFC4010 itself contains three transistors and five resistors.

Another low-level audio amplifier is the MC1303P in the popular dual in-line 14-pin package. This dual audio amplifier was designed to be used as a preamplifier in stereo phonographs and similar equipment. It provides 60 dB of gain and is useful where high gain and two separate amplifiers are needed.

The MFC4000 is a 0.25W audio power amplifier with 15 mV sensitivity. It contains six transistors, three diodes, and five resistors. The MFC4000 uses the same small package as the MFC4010 and also has only four terminals: input, output, supply voltage, and ground. Its 250 mW of audio output may not seem like much, but it is quite satisfactory for many applications, such as pocket radios, and home equipment, where the noise level is not very high. When used with an efficient speaker, that quarter watt will drive you out of the room.

The MFC4000 draws very low standby current, typically only 3.5 mA at 9V. Perhaps the best feature of the MFC4000 is compactness. A whole audio output stage takes up very little space.

The MC1306P is also a 250 mW audio amplifier, but it includes a preamplifier, giving it a sensitivity of 3 mV for full output—considerably higher gain than the MC4000. It's packaged in a new eight-pin plastic package that looks like a shortened dual in-line package. Four transistors in the preamplifier section and ten transistors in the output section are contained in the small package. The two parts are independent and can be used in cascade with other circuitry, such as a volume control or filter between them. Like the MFC4000, the MC1306P is designed for 9V operation and has a similar low zero-signal current drain (4 mA). Typical harmonic distortion is only 1%.

A typical application of the MC1306P is shown in **Fig. 5**. This is a high-gain 250 mW audio amplifier for use in a portable receiver. Its total gain is 1000, or 30 dB. Only a few external components are required, but as with all these ICs, the component leads should be short to prevent high-frequency oscillation.

The next IC has been available for some time in an expensive hi-rel (military term for "high reliability") version. The recent introduction of a low-cost, relaxed-spec version makes it much more interesting. This device is the MC1454G. It is similar to the older MC1554G, but as mentioned, has relaxed specifications and a much lower price, $3.30 instead of $14.25.

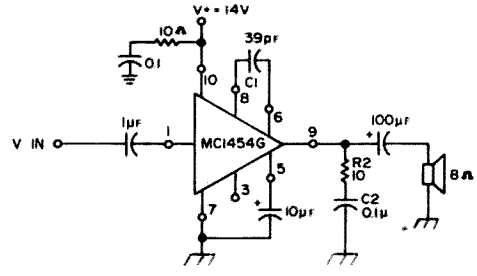

Fig. 6. Audio power amplifier has 1W gain of 10; input impedance of 10 kΩ. An external heatsink is required. The HEP593 can also be used in this circuit with similar results.

Figure 6 shows a 1W audio power amplifier. You'll notice that it uses no transformers, and operates directly from 12.5 to 14V. The gain of this circuit is 10, and the input impedance is 10 kΩ. An external heatsink must be used with this device for maximum power output.

The HEP 593, readily available at almost all electronic stores in the country, is similar to the MC1454G. Either of these devices makes an excellent output amplifier for use in mobile or home equipment. Its IW of audio power is adequate for most ham uses,

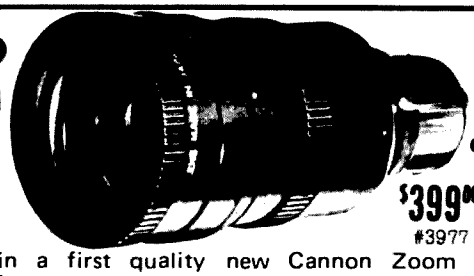
except modulating large AM transmitters, which hardly anyone does any more. Motorola Application Note AN-401, "The MC1554: A One-Watt Monolithic Integrated-Circuit Power Amplifier," gives more information on applications of this useful circuit. As mentioned, the MC1454 is a relaxed version of the MC1554, and the circuits described apply in almost cases.

I-F Amplifiers



A number of new i-f amplifiers have been introduced recently; many are of great interest to the ham. In addition, one that's been around for a few years takes on a new interest in view of its recent reduction in price from $4.25 to $1.50.

The MC1350P is perhaps of greatest interest. It features very high gain at frequencies up to 60 MHz and also includes provision for very wide-range agc. Power gain is typically 50 dB at 45 MHz, and agc range is 60 dB minimum. It has very low feedback capacitance, thus does not need neutralization in spite of its very high gain. The device is designed for operation on 12V from a single power supply, unlike many of the earlier ICs. The MC1350P was designed for use in television receivers; however, it's equally valuable for many other uses, such as i-f amplifiers at any frequency up to 60 MHz. Typical gain at 45 MHz is 50 dB; at 10.7 MHz, it's 58 dB, and at 455 kHz, 62 dB. Noise figure at 60 MHz is a respectable 9 dB, but you probably would want to use a low-noise preamp if you were using this i-f amplifier in a microwave receiver. For other applications, this noise figure is more than adequate. Typical circuits for the MC1350P are shown in Fig. 7. Component values are given for frequencies of 455 kHz, 10.7 MHz, and 45 MHz.

Very similar to the MC1350P is the MC1590G, a higher-performance version sealed in a metal can for use in military equipment. The MC1590G costs $5.60 in single quantity, so you can see that the MC1350P at $3.75 would be of much more interest in most ham applications.

Either the MC1350P or the MC1590G also makes an excellent video or audio amplifier for any application requiring very wide range agc, such as speech compression circuits.

A very simple receiver providing quite good performance could be made using a few of these integrated circuits. Discrete dual-gate MOSFETs are better in the front end: an MFE3007 is an excellent rf amplifier. An MFE3008 mixer with a separate oscillator could feed an MC1350P i-f amplifier, then a detector and MC1306P audio output amplifier.

An older, but very good, linear IC is the MC1550G rf/i-f amplifier. This is a much simpler circuit than the MC1350P, but it also offers very wide agc range, high power gain (typically 30 dB at 60 MHz), good noise figure, and extremely low feedback capacitance. The MC1550G used to cost $4.25; now it's down to only $1.50, which makes it very attractive for many applications.

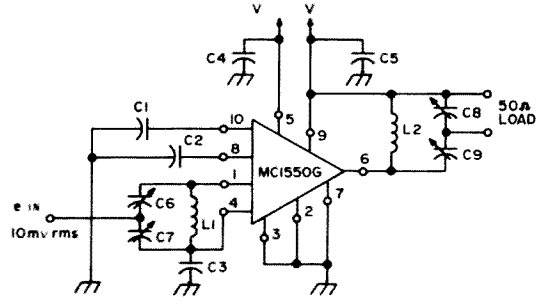

Fig. 8. MHz amplifier with 25 dB gain and good agc characteristics. The HEP 590 can also be used in this circuit with similar results.

Many circuits have been described using the MC1550G, increasing its appeal to the ham builder. A typical example is shown in Fig. 8. This is a 60 MHz amplifier with 25 dB gain; it can furnish excellent agc. Motorola Application Note AN-247 "An Inte-

grated Circuit RF/IF Amplifier," provides more information on using the MC1550G.

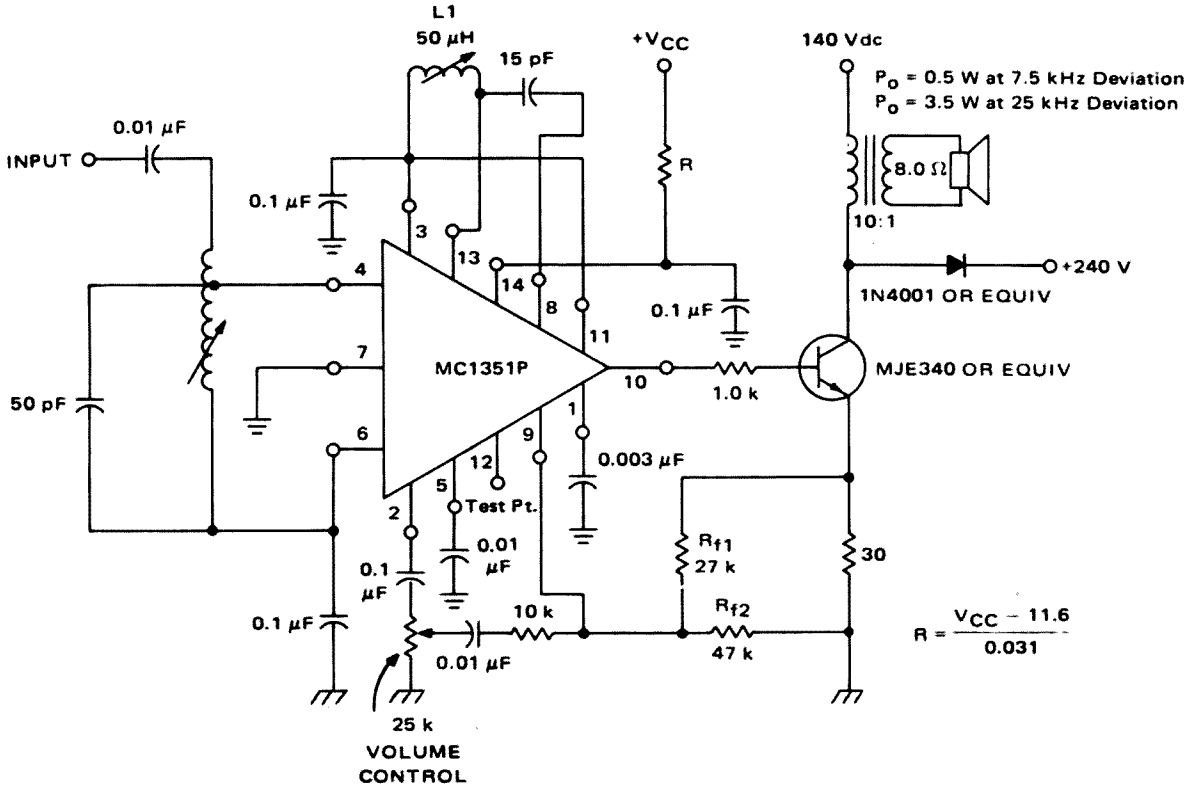
The HEP590 is similar to the MC1550G. Both are packaged in the TO-5 metal can.

One of the most interesting of new linear integrated circuits is the MC1351P. This wideband FM amplifier provides i-f amplification, limiting, detection, and audio amplification. This circuit is almost a complete FM receiver, fitting in well with the recent amateur repeater trend. The MC1351P typically has 65 dB gain. It uses an interesting FM detector that requires only one external coil and capacitor in its resonant circuit.

The MC1351P was designed for use in the 4.5 MHz sound channel of television receivers (5.5 MHz for Europeans); however, it's very adaptable for use in FM receivers, either commercial FM broadcast receivers at 10.7 MHz, or in mobile communications receivers. A typical circuit using the MC1350P is shown in **Fig. 9**. This is a complete FM i-f system. It is most adaptable for use in the home, since it requires 140V dc for the audio power amplifier. However, a similar type of circuit can be used at 12V with a different audio amplifier. Motorola Application Note AN-468, "A Monolithic Circuit for Television Sound Systems," describes the use of the MC1351P in TV reception. The ham can easily convert this for FM reception in communications work.

Balanced Modulator

An interesting new linear IC is the MC1596G balanced modulator/demodulator. This circuit is a complete SSB product detector or a balanced modulator for generating DSB with no coils or external tuned circuits. It requires only a few resistors and



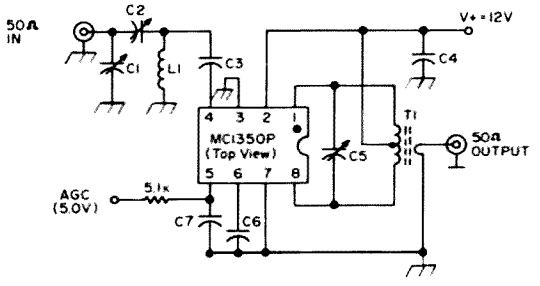


Fig. 9. Complete FM i-f system. Though this circuit was designed for use in TV receivers, it is also excellent for ham FM reception. For portable use, another type of output stage would be preferable.

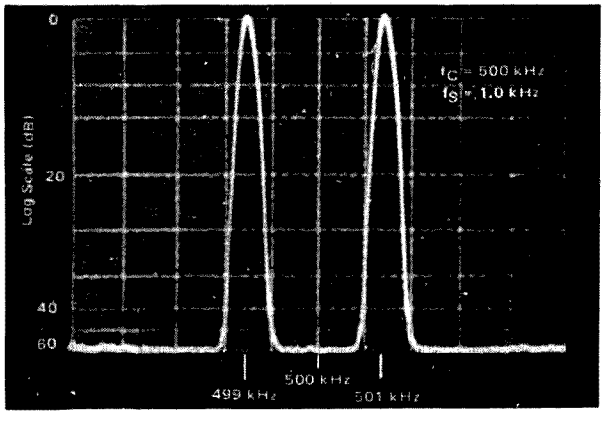

capacitors. **Figure 10A** is a typical balanced modulator circuit using the MC1596G. **Figure 10B** also shows the typical double-sideband-output spectrum that it produces. The 500 kHz carrier is completely eliminated, at least to the definition of the spectrum analyzer used, about 60 dB down. The MC1596G can easily provide 40 dB of carrier suppression at 9 MHz, perhaps the most popular frequency for generating SSB signals these days.

A

Fig. 10 (A). Balanced modulator using MC1596G and (B) double-sideband output spectrum. Carrier rejection is greater than 60 dB without using any coils.

B

At $1.75, the MC1596G is not inexpensive; however, its versatility and the simplification and high performance it brings to a circuit should make it very popular and we will likely see many applications of this type of device in the future.

Incidentally, to those of you who follow the engineering magazines, the MC1596G is a simplified cousin of the MC1595 multiplier that has been attracting a great deal of attention. The monolithic multiplier seems to be the new analog building block, similar to the op amp in its versatility, and can be

JEFF-TRONICS

4252 Pearl Rd. Cleveland, Ohio 44109

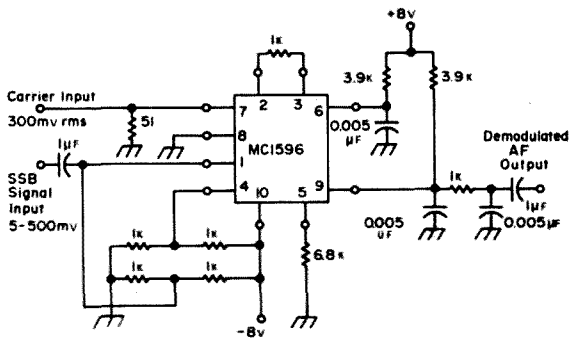

Fig. 11. Product detector using MC1596G balanced modulator/demodulator.

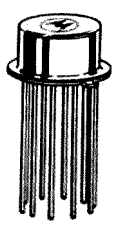
used in many different applications. The MC1596G is considerably simpler and less expensive; however, it still provides excellent performance in many applications.

Operational Amplifiers

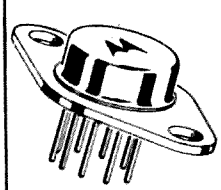
Many circuits have been described using operational amplifiers, or op amps. Op amps have been around for many years, and cost as much as $200 at one time. Now you can buy a very high-quality, high-gain operational amplifier, the MC1439L, for only $2.70 in single quantities. This op amp is a relaxed version of the MC1539, which is widely used in military and commercial equipment. This circuit, though inexpensive, is extremely versatile, and can be used in almost any circuit requiring an op amp.

Conclusion

This article has provided a quick look at some of the new linear ICs of particular interest to hams. It has provided only very sketchy information, however. For more information on any device in which you are interested, you can write to the Technical Information Center, Motorola Semiconductor Products, Inc., PO Box 20924, Phoenix, AZ 85036. The data sheets on the devices provide a great deal of information, and where mentioned, application notes are also available.



I hope this description of these circuits helps to convince you that linear ICs are now at the stage where hams can use them in their equipment. They are more economical circuits using discrete devices in many cases, and are much easier to work with.



... WA4KRE■

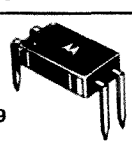


Table I. Linear ICs of Particular Interest to Hams

TYPE NUMBER	DESCRIPTION	CASE	PRICE (1-99)
Voltage Regulators			
MC1460G	20V, 250 mA	602A	$ 5.25
MC1460R	20V, 600 mA	614	6.75
MC1461G	Voltage Regulators 35V, 250 mA	602A	6.79
MC1461R	35V, 600 mA	614	8.25
MC1469R	35V, 600 mA	614	6.75
Audio Amplifiers			
MFC4010	Wideband amplifier, 60 dB gain, to 1 MHz	629	1.85
MC1303P	Dual audio preamplifier, 40 dB gain	605	5.25
MFC4000	250 mW audio power amplifier, 15 mV sensitivity	629	2.10
MC1306P	250 mW audio power amplifier, 3 mV sensitivity	626	2.90
MC1454G*	1W audio power amplifier	602B	3.30
IF Amplifiers			
MC1350P	Agc i-f amplifier (to 60 MHz), 58 dB gain at 10.7 MHz	626	3.75
MC1550G**	Agc i-f amplifier (to 100 MHz), 25 dB gain at 60 MHz	602B	1.50
MC1351P	I-f amplifier, FM detector, audio preamplifier 65 dB gain at 4.5 MHz	605	4.10
Balanced Modulator			
MC1596G	Balanced modulator/demodulator, 40 dB carrier suppression at 10 MHz	602A	7.15
Operational Amplifier

THE GLOP WILL GET YOU- IF YOU DON'T WATCH OUT

This is an old story but it's worth telling again. Twinlead can deteriorate in its performance at radio frequencies, especially when it's wet. This is old hat to most hams that have been around a while, but we tend to forget. This forgotten point was re-emphasized to me a few nights ago. I tried to fire up the rig on my favorite band, but the antenna just wouldn't take any power. All received signals sounded normal, so my suspicion was directed to the twinlead; about 75 feet of it feeds the antenna.

There had been a small rain shower, and the twinlead was covered with a thin layer of moisture, something resembling dew. Since it was late, I resolved to do something about it the first thing in the morning. Next day, the flat-top was lowered and the twinlead was scanned. Sure enough, there was a thin coating of dirt, dust and a dark sooty-looking compound. This was carefully removed with a soft piece of paper towel, which had been dampened with water. It is surprising how this stuff will pile up on your antenna insulators and transmission line. This is the same stuff that attaches itself to your car, only you are more aware of it since you must see through the windshield in order to drive. It's also piling up on your antenna system at the same time, the big difference being that you can't drive your antenna to the carwash every time it accumulates a fresh layer of dirt. But it's piling up nevertheless.

This is not something peculiar to the amateur fraternity. Couple of years ago, there was a big blackout in a Canadian province. It turned out that carbonaceous compounds had attached themselves to the high tension insulators—those big six foot insulators—and the next time it got damp, the circuits arced over. Everyone gave up on TV for that night, and went back to candles for light!

Once the black glop is wiped clear of your twinlead, it is fairly simple to wipe a little "magic compound" over the twinlead and your troubles will be gone for quite a while. The magic stuff in this case is the Dow Corning type 4 compound, a silicone base surface-coating compound, sometimes called "DC-4." This stuff will make your twinlead shrug off water like a duck's back. It is available at Allied Radio and at other well-stocked suppliers. The cost is $2.00 for a two ounce tube. At first blush, this may seem rather high. But you don't smear it on, you wipe it on with your fingers. And remember only a thin, thin layer is needed. Anything thicker than one molecule deep is unnecessary. I have a tube on hand that's been around for years. Sure it's an old story, but worth telling once more.

By the way, you can use the same compound for waterproofing the ignition wires and other components in your car which handle high voltage. The family car will be less prone to fail when you drive through a deep puddle, and the XYL will think you're an electronic genius.

(continued from page 12)

Mismanagement, Incompetence, or Both?

Dear Mr. Green:

Your November editorial and Dave Mann's article regarding the ARRL were a pleasure to read. My experience as a ham has been limited as I have held a General license for less than six months. I have no basis to judge your statements regarding ARRL's lack of leadership and initiative in the technical areas surrounding amateur radio. However, as an attorney, I feel competent to comment on the other matters raised.

If what you have reported is true, I must conclude that the leadership of ARRL is grossly incompetent, dedicated to the demise of amateur radio, or mismanaged in order to suit the self-interest of a select few. A viable, dynamic company or organization, if it is seeking its greatest productive effort, cannot afford to hold $618,000.00 in cash securities. I would immediately question those in charge as to where the funds are kept, at what interest and on what basis does ARRL decide which banks will be favored with their deposits?

As you may know, any cash reserves over $100,000.00 are usually suspect by Internal Revenue as accumulated surplus. Good reason must be shown as to why the amount is carried instead of distributed to shareholders. A penalty in the form of 27½% can result if a reasonable basis fails to exist. Does a reasonable basis exist for ARRL to carry funds in excess of $100,000.00 without distributing the rest in benefits to its members? I think not. Why isn't this money being used in the many areas of amateur radio that are in dire need of increased activity? My experience in commercial affairs leads me to conclude that someone's self-interest is being held in higher regard than that of the majority. I believe that from reading your comments under ARRL National Convention Report, ARRL Articles of Association Waived, etc., that you have reached the same conclusion.

The success of your magazine is an indication that the masses of dedicated amateurs agree. They can see what is happening to their dollars and privileges. How could ARRL ever give its blessing to incentive licensing and still maintain the interests of the majority of amateurs?

I have compiled a list of some objectives which I believe would be in the best interests of the great majority of hams. Unfortunately, I also believe that ARRL would not lend support to them. They are:

1. Devising of a plan of incentive licensing which would return the frequencies lost, and further grant new frequencies for those who have advanced past General.
2. Establishment of effective representation in Washington. Greater privileges for the amateur can only come through the FCC and Congress; without their help we are powerless. How creative effort has never been utilized in this area previously is beyond belief. The possibilities are endless. It is not hard to foresee the day when amateurs could be compensated directly by the Government in return for the maintenance of an emergency communications network. Government surplus equipment could be offered directly to the amateur at reduced costs. These ideas may be "way out" to some, but think a moment about the great advantages now being extended to other special interest groups.
3. Improved public relations.
4. Recruiting drives.

I cannot imagine how an educated populace like the amateur radio community could remain silent for so long a period of ARRL inactivity. The ARRL leadership structure is, in my opinion, guilty of gross mismanagement.

Like yourself, Mr. Green, I believe that a change in ARRL thought and direction would mean greater growth for amateur radio.

I believe the time has come for an all-out drive to elect a complete slate of new directors who share our thoughts and opinions. Your magazine is one of the few vehicles available for such an objective. I strongly urge you to consider such a campaign. If I can be of any assistance, please do not hesitate to contact me.

What Price ARRL?

Dear 73,

I have been reading your magazine for a few years now and I have yet to become tired of its content. I was disgusted with the others within a year. They always have the same articles in them. I always look forward to 73 arriving at my shack.

I have been reading with interest your feature "Leaky Lines." One paragraph of it is worth a whole issue of QST. The boys at ARRL have been in amateur radio so long they have forgotten what it's like to be a relatively new ham like me of only seven years. In my opinion, it's the ARRL that is stagnating, not the general ham population. They beat down any idea for improvement which is the least bit contrary to their way of thinking.

I read the minutes to the May board meeting in QST after reading them in 73 and QST's version is funnier. How these people can waste so much time and money doing absolutely nothing is unbelievable. I feel sorry for those who join ARRL expecting betterment of amateur radio and then seeing it spent on those worthless board meetings. You tell me to support ARRL because it's the only national organization we have. By joining I would support this clown circus in Newington. No sir! I won't give them any more of my money.

They sit and argue about putting info on repeaters in the handbook, when there should be no argument at all. Then QST has the guts to ask for articles on the subject, which they don't pay for, and yet they have a PAID technical staff at ARRL. What are they doing? Dusting off the spark rigs in the museum?

Any outfit can print handbooks, logsheets, and DX maps. And W1AW ought to be in the center of the country, not sitting out on the east coast. They even had to start up a code practice station on the west coast because nobody could hear that one squeaking out east. As for FCC petitions, anyone can get one up so who needs ARRL?

Jerome Grokowsky **WA9HCZ**

Pulsars, Quasars, and the Like

Dear Sir,

As Mr. Hoisington's article was, to me anyway, a rather controversial one, and perhaps inaccurate here and there, readers may find additional comments interesting.

The subject matter is very tricky and I only wish I were capable of understanding more about these seemingly basic laws. I recall fighting my way through a quantum mechanics course only to find electric fields are quantized, too! That's where I stopped!

Your magazine is very enjoyable, and has stimulated me to the point where this is the first letter I've written in response to an article in any magazine.

Ed Schweitzer

Dear Sir:

The article by Bill Hoisington, K1CLL, in the September 1969 issue of your magazine reflects the work of a good inquisitive and active mind, and I certainly agree that satisfactory explanations of quasars and pulsars are in short supply.

I recall a book written by a Mr. Dolbear, entitled *Matter, Motion and Ether.* The book was written around 1900, and Dolbear was a physicist at a university in this country, perhaps at Duke, but probably at Tufts University. It has been five or more years since I've seen the book, and it is not now available to me, and I apologize for the scanty details on the book and its author.

However, I recall he investigated the ether problem from a similar point of view, that is, vortex waves, or rings. I was intrigued enough to build a number of vortex ring generators and spent many days fascinated by their behavior. For example, one ring may be made to pass through another if they are directed on the same path but head on in exactly opposing directions. I also recall that a slight angle between the paths was sufficient to upset this amusing effect. Note that this is rather contradictory to the behavior of electromagnetic radiation.

After reading elsewhere that soldiers during the Civil War were reportedly observed to fall as the result of cannon blasts far from the soldier (this refers to some soldiers whose position was not coincident with the trajectory of the projectile), I

experimented with devices capable of producing much larger vortex rings than the coffee can devices could. I succeeded in extinguishing candle flames at 20 to 30 feet ranges with a ring about four or five inches in diameter. This was done in a college dormitory where drafts perpendicular to the propagation direction were uncontrollable. That the drafts interfered has more significance than making it difficult to aim my generator at a small, distant target.

Consider the experiments of Michelson and Morley in California around 1900. The ether mystery was one target of their classic and famous interferometer experiments. I refer to *Studies in Optics* by A. A. Michelson, where he describes the details of his work in relation to the controversial theories of the day. Any ethereal wind, perhaps as a result of the earth speeding along its orbit, should cause differences in propagation times along the legs of the interferometer. No differences were observed, a result strongly supporting the no-medium-necessary camp. Please recall how the cross drafts upset my vortex ring experiment, and note the conflicting but, I think, explained results.

The ether matter deserves questioning on other bases, but the proof is in Michelson's experiments. Basing theories on the postulation of an ether will lead to results as disastrous as the results for planetary motion based on an earth-centered system.

May I also comment on Mr. Hoisington's discussion of the unacceptable nature of the dual nature of light, i.e., waves and particles. In quantum mechanics, the wave-particle problem is attacked from a probabilistic point of view, and the results are in excellent agreement with observation. For example, radiation in quanta (photons) and Heisenberg's uncertainty principle are results predicted by quantum mechanics, and apparently not questioned by Mr. Hoisington.

At this point, where quantum mechanics and relativity are starting to merge on me, I stop. But the theory and confirming experiments from here on add more and more support to two points I've tried to illustrate.

1. There has never been evidence presented to support the existence of an ether.

2. A dual nature is evidenced in light when considered in terms of our concepts of particles and waves.

I hope I am not insulting by writing that I at first thought this to be an April QST type of article, and further hope that I have not been taken in on a spoof.

Edmund O. Schweitzer III WA3LPD/K9ZXE
3507 Lancer Drive
Hyattsville MD 20782

Ed. Note. Mr. Hoisington is quite earnest in his theories.

CW in Perspective

Sir:

For the last fifteen years of my life I have been directly involved in the field of electronics and radio; my duties have taken me from design to test, to maintenance sales and every other aspect of the field of electronics, not necessarily in the above order; a number of these years to the present time I have shared with amateur radio, and I must say, they have been most enjoyable.

My interest has been focused lately in the current controversy about the latest changes in regulations by the regulatory body of amateur radio, the FCC. I have followed with interest the opinions of different sectors of the "ham population" in the States, as well as reaction from outside the country, and when viewed individually, I think the arguments in favor are as strong as the arguments against them.

I, however, decided to look at them from a different point of view... The purpose of amateur radio in the United States as well as in most countries around the world, is one of "service to the community," "service to society," and self-improvement of the operator, in both technical and mental aspects.

The amateur frequencies in this country have been divided in several portions, where operations in one or other mode are permitted or restricted; mainly we can observe a lower part of a band of frequencies used for CW and another part being used for "phone" work, with some more divisions allowing certain privileges to certain classes of license. In order to qualify for them, prospective amateurs have to pass a test which will measure their ability and knowledge in the field of radio amateurism.

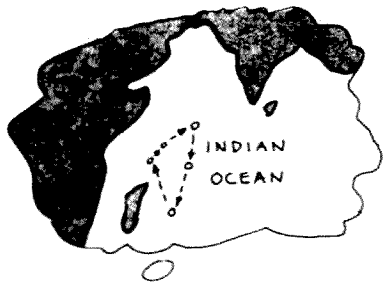
I have been very interested in the emphasis being placed on CW operation, higher and higher speeds are required in order to qualify for general, advanced or extra class; presumable we are assuming that this ability to operate the key at higher rates is a service to society or a way to improve the operator and prepare him for a better future... nothing could be further from the truth, and don't get me wrong: I have absolutely nothing against CW operation *per se*, like I have nothing against radio control or RTTY or any other form of expressing one's preferences in the field of radio, but I do feel that the unnecessary restrictions and regulations placed on the amateur community by these laws are repressing progress and producing an effect completely opposite to the one originally intended by the FCC. Let me make this clear, I am going to submit to you very convincing arguments that can be checked by anybody at any time, but I do not propose that we do away with CW operations; quite the contrary, all the amateurs that prefer this type of operation should continue to do so without any restrictions of any kind, but the emphasis placed on it should be channeled to some other fields of research more useful to society and the country.

For the past few months I have been researching industry, schools, and government agencies in the Western area of the USA, and sad as it may be, the consensus is unanimous, without exception: CW is a thing of the past, of another time, long gone. It seems that only the ham fraternity clings to it, it will not leg go—perhaps due to the FCC, perhaps due to the fact that we are stagnant, more probably a combination of both facts, the truth is that CW regulations are holding down progress in amateur radio, it occupies a great portion of our frequencies that could be used to research some more advanced means of communication and perhaps recover the leadership that we lost when Teletype and computers were given the job of transferring intelligence from one point to another.

A Los Angeles City School official told me that as far as he can remember, there was only one school in Los Angeles that ever had a course in telegraphy, and that course was discontinued a long time ago FOR LACK OF JOBS in the industry to place the graduates.

A head engineer for the telephone company told me that as far as he remembers, telegraphy is not being used nor had it been used for a long PERIOD OF YEARS.

Good old Western Union representatives told me that telegraphy was too slow and inefficient a way of communication to be used any more, he knows of no operation in the USA that uses CW, and he can remember none.



It seems to me that those are pretty conclusive statements, and a quick check around the country will show that conditions are the same. The question is: What are we being led to; are we preparing ourselves to serve the country in case of need; are we ready to be a service to society in case of emergency or are we preparing ourselves to provide a disservice to the community, with our antiquated practices; and perhaps eventually lose our frequencies to some other service that proves to have more foresight than we did. Are we getting ready to go to the planets and stars with our high speed: 25 words a minute; or should we be getting ready for a more sophisticated way to convey intelligence at *millions of bits per second* and more...

It is time that those who represent the amateur community, look at the future, at the present, and at our activities. Since the first wireless was turned on, we have progressed to the fantastic speed (new regulations) of 25 words per minute. It is time that we really make some progress, it is time that the FCC and the members of the regulatory bodies take a new look at amateur radio, the ARRL, the amateur publications; and all amateurs should express their opinions and views on the subject. The growth of amateur radio has come to a standstill, and it is our responsibility to do something for it, to give a new challenge to our group; it is the responsibility of its leaders to petition the FCC and Congress for the necessary laws and regulations to make our goal possible.

Micro-Mitter compared to a Vibroplex Lightning Bug.

MICRO-MITTER ... TEENSY-WEENSY QRP ON 40

In the March, 1968 issue of 73, an article was published entitled, "Mini-Mitter; the Ultimate in Miniatures!" Mr. Pyle suggested the possibility of having built the smallest CW transmitter to date. Several months earlier, however, I constructed a complete CW transmitter which, with the power supply, fits into the case that the crystal came in (for convenience, the crystal remains outside, plugging into an internal socket).

The circuit is a typical crystal oscillator circuit, using a 2N2188 transistor. The unit was built to operate on 40 meters, but with proper adjustments in the LC section and crystal value, any low frequency can be obtained. The parts are strictly junkbox, and the smaller the better. I used a miniature tuning capacitor from a junked transistor radio, and wound the coil so the pair would resonate at 40 meters. The battery is a watch-type mercury cell, with its socket made from two pieces of sponge rubber and wire contacts. Any suitable glue can be used to hold everything together.

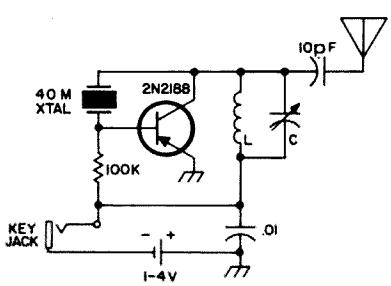

Fig. 1. Schematic of Micro-Mitter. L and C should resonate at the crystal frequency.

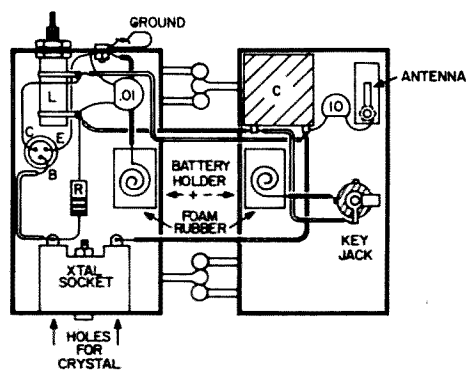

Fig. 2. Case layout. The case is opened on its back, and the battery is removed for clarity.

To operate the unit, attach antenna and ground wires to their respective clips. Push the key down and tune the variable capacitor for maximum signal (as indicated on your receiver—don't worry, it won't burn out the front end). I haven't measured input or output power on the rig, but I carried on a QSO with a station 50 miles away. Not bad for something you can lose in your shirt pocket!

A = Next higher frequency may be useful also.

B = Difficult circuit this period.

A Simple

Almost any integrated circuit operational amplifier can be used to build this Q-multiplier. Its advantages are extreme circuit simplicity and a useful frequency range that extends from audio frequencies to almost all i-f frequencies. Both the peaking frequency and Q can be made variable.

Both vacuum tube and transistor Q-multiplier circuits find wide application in improving the selectivity of transceivers and receivers, particularly on CW when the Q-multiplier is used to peak the i-f response following a steep-skirted crystal or mechanical SSB filter. The Q-multiplier provides a very narrow bandpass but if used alone does not provide steep skirt selectivity. When used in conjunction with an SSB filter, however, the latter provides the necessary skirt selectivity (see **Fig. 1**).

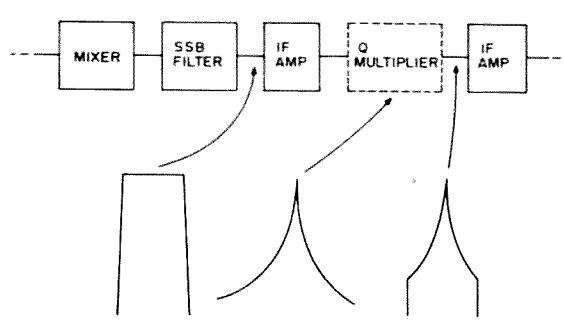

Fig. 1. Placement of Q-multiplier after SSB filter provides effective narrowband response for CW reception.

Integrated Circuit Q Multiplier

John J. Schultz W2EEY
1829 Cornelia Street
Brooklyn NY 11227

The Q-multiplier described in this article is meant to be inserted between any i-f stage in a transceiver or receiver following an SSB filter. It can be easily switched for broadband operation so it does not affect normal SSB operation. Since it is adjusted for unity gain, it does not upset any gain relationship in the i-f stages. As compared to vacuum tube and transistor-type Q-multipliers, the circuitry of the unit is extremely simple due to the use of an integrated circuit operational amplifier. The unit can be successfully used on frequencies far higher than those normally used with vacuum tube or transistor Q-multipliers up to 5 MHz or more, depending upon the integrated circuit used. The circuit can also be used at audio frequencies, if desired. One can also build an audio selectivity unit for outboard use when it is not desired to make internal modifications to a transceiver or receiver.

Circuit Description

The Q-multiplier is constructed around an integrated circuit operational amplifier. Many such amplifiers are available on the market at prices starting at a few dollars. The main requirements for choosing a suitable unit are that it have a differential input (inverting and noninverting inputs), and a single-ended output and a bandwidth sufficient for the frequency of operation. For example, Fairchild 709T amplifiers are available for about $3 and are usable up to at least 500 kHz. I built a unit using a Fairchild 741 which is usable up to 1-2 MHz. Other amplifiers such as a Motorola MC1530 can be used up to 10 MHz.

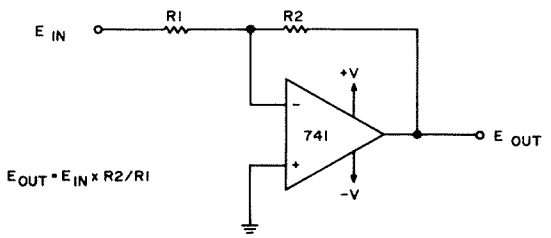

Fig. 2. Basic type of integrated circuit operational amplifier with a differential input and single-ended output that is needed for the Q-multiplier circuit.

Figure 2 shows the schematic of the type of operational amplifier which is used and the formula for the output voltage of an ideal amplifier. The Fairchild 741 amplifier which I used requires no external frequency compensation components. Other amplifiers may require a few external components for this purpose as specified on their data sheet. The frequency rolloff components should be chosen such that the amplifier gain starts to decrease just above the frequency where it is used as a Q-multiplier. There is no advantage to having the gain "rolloff" at any higher frequency and would just make the amplifier more susceptible to oscillation due to a stray feedback path via external components. As noted from the gain formula, the gain of the amplifier depends upon the ratio of R2 and R1. If R2 is made equal to R1, the gain is unity. The Q-multiplier effect is based upon replacing R2 with a parallel resonant circuit which will present a very high impedance at one frequency and, therefore, maximize the overall gain at that frequency. Positive feedback is also used to enhance the Q-multiplying effect of the circuit.

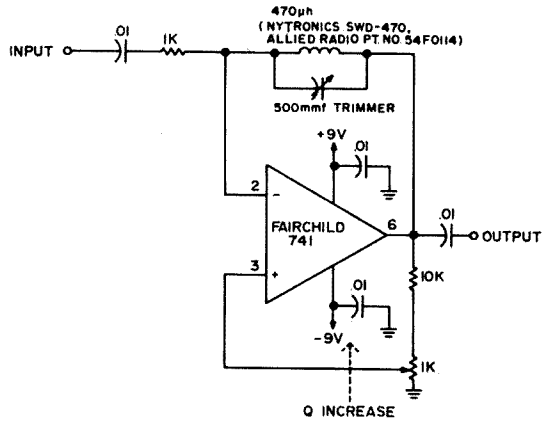

Fig. 3. Circuit of the Q-multiplier as constructed for a 455 kHz i-f

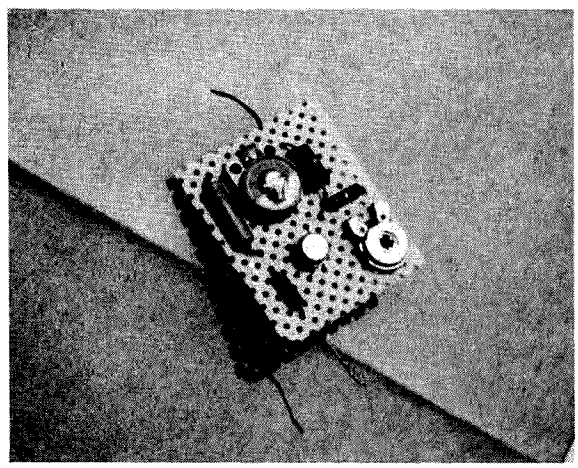

Figure 3 shows the schematic of a practical Q-multiplier circuit with the LC circuit resonant at 455 kHz for use in a 455 kHz i-f chain. Positive feedback is supplied via a 1 kΩ potentiometer. As with other Q-multiplier circuits, the Q can be increased by regulating the feedback until a point is reached when the unit will break into oscillation. The Q-multiplying effect is most effective when components are used for the resonant circuit which in themselves have a good Q. The inductor used for the 455 kHz Q-multiplier is a molded type which provides a Q of about 55 at 455 kHz by itself. The circuit can multiply this value by about 50 times or more. Another suitable inductor can be obtained by using only one or two sections from a regular 1 mH rf choke. The trimmer capacitor is used to set the frequency of the Q-multiplier in the middle of the i-f passband. It can, of course, be used as a variable tuning control for the peaking frequency of the unit. The input resistor, although shown with a nominal value of 1 kΩ, should be chosen so that the gain of the overall circuit is approximately unity.

Construction and Adjustment

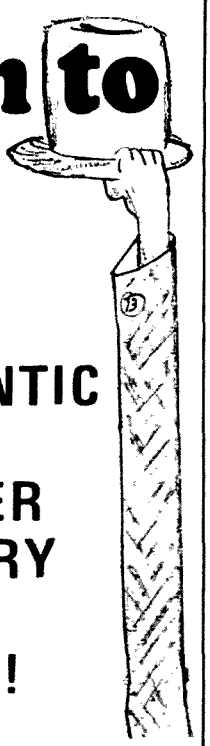
There is nothing critical about the construction of a unit utilizing the circuit described as long as the various lead lengths are kept short. The photograph, for instance, shows how the various components can be directly wired together on a small piece of Vector board. The board itself can be directly mounted near the i-f chain in a transceiver, receiver, or together with the potentiometer used for feedback control if the latter is panel mounted.

If the Q-multiplier is not made tunable, the initial adjustment consists of peaking up the LC circuit. This can be done with the unit connected in an i-f strip and using any test signal centered in the i-f bandpass. The adjustment is best done with the feedback control set for minimum Q and with a barely audible CW test signal. The input resistor value should be then chosen for approximately unity gain. The adjustment is not difficult and need not be made exactly. The output level produced by a test signal without the Q-multiplier connected is noted. Then when the Q-multiplier is used, the input resistor is chosen so that the output level remains approximately the same. With most transistor i-f stages, the value of the resistor needed will be about 1-5Ω.

Bypassing of the Q-multiplier can be done in a number of ways in order to allow for normal SSB reception. If the Q-multiplier is made frequency tunable, it can simply be tuned outside the i-f bandpass. In order not to have the i-f gain decrease too far when doing this, the input resistor must be chosen for unity gain to take place when the Q-multiplier is just tuned outside the i-f bandpass. This will result in some increase in gain when the Q-multiplier is tuned to the center of the i-f bandpass but normally the

The Q-multiplier components can be directly wired together using Vector board mounting. In this case, a PC board potentiometer is used to set the operating Q rather than making it continuously variable.

result will not be objectionable. Another way to bypass the unit is to replace the LC circuit with a simple resistor equal in value to the input resistor (as in **Fig. 2**). The switching action can be accomplished by using a 1 kΩ potentiometer for the feedback control which also incorporates a SPDT switch. The switch must be wired such that the resistor replaces the tuned circuit when the wiper arm of the potentiometer is at ground potential.



Summary

The simple Q-multiplier circuit described can be used for a variety of purposes besides that of improving i-f selectivity. It is useful for improving the Q and selectivity of a variety of tuned circuits as they might be used in FSK converters, audio filters for distortion tests, etc. Stagger-tuned circuits used in series can be formulated to provide a variety of bandpass shapes, often replacing more expensive components where bandpass shape factor is not important.

The permission of Dick Gerdee of Optical Electronics to present this circuit, which he originally developed, is gratefully acknowledged.

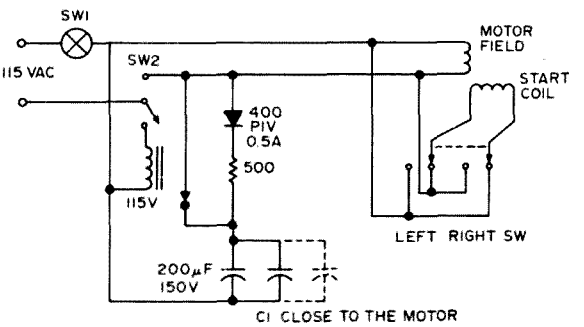
QUICK STOP & REVERSING For Antenna Rotator

My antenna rotator is a homebrew type made with a 1/3 hp motor. An early problem I notices was that the rotor had a tendency to keep turning for a few degrees after the stop command. So I use a discharge of capacitors in the motor as an electric brake. I also applied this technique to a small lathe that I bought to build 432 MHz cavities. It works great. When used in the



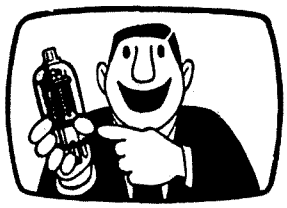


Fig. 1 Extra contact in the go switch

antenna rotator, the brake also provides an instant reversing capability. You need only an extra contact in the off-one switch to command a heavy duty relay near the rotator. When you are turning the antenna, the silicon rectifier charges a bank of capacitors, and when you stop, the condensers are discharged in the motor, bringing it to an instant halt. Put the capacitors in one by one until you get instant stop with your motor. (It is not good for dc motors.)

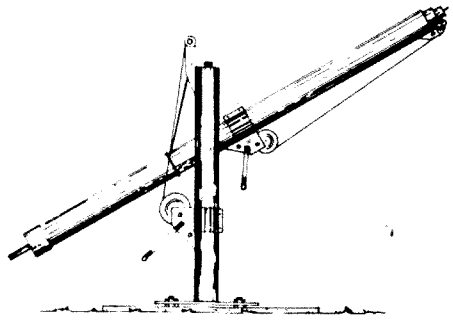
NEW PRODUCTS



Hi-Power Balun Offers Lightning Protection

The *Big Signal* W2AU balun comes in either 1:1 or 4:1 conversion ratios, and boasts a full kilowatt (the California kind) capability, built-in lightning arrester, and a bandwidth of 3 to 40 MHz. Manufactured and distributed by *Unadill Radiation Products, Unadilla NY 13849.*

Crank-Up Mast has Tiltover Feature

Tristao is now marketing a crank-up mast. The two-section mast goes to 49 ft and the three-section version reaches a towering 66

EASY 2 STEP INSTALLATION

ft. The rotator rests right near the ground, simplifying service of this mechanism. The complete system (called Magna-Mast) can be installed entirely by one man. The tiltover mast enables work to be done on the antenna from the ground, a safety feature which should appeal to amateurs with weak hearts. Both models are hot-dipped galvanized steel. Drop a note to *Tristao, Box 115, Hanford CA 93230.*

Swan Develops Bandpass Antenna For VHF Bands

The Swan bandpass antenna, developed for use in home television reception, has recently been adapted for the 2 and 6 meter amateur bands. Swan's bandpass antenna has the combined properties of constant impedance match across the entire passband of response, with gain superior to that of an equivalent-sized yagi. The antenna features a very high front-to-back ratio as well as front-to-side in both the X and Z planes. Match is in the order of 1.1:1, and gain across the entire design bandpass remains virtually constant.

The Swan bandpass array uses four driven elements, and saturates the first director with virtually all of the power radiated from those active elements. Since the first director sees four driven elements at four different distances, it responds to the designed bandwidth, giving gain at four different frequencies, hence the bandpass response. Similarly, each dipole is matched to four separate frequencies, giving a constant impedance match across the design bandpass.

The advantages are:

- Controlled bandwidth response
- Controlled bandwidth impedance
- Rejection of undesired frequencies and noise above and below desired bandpass response
- Unidirectional response
- Improved signal-to-noise ratio
- Greater gain than the yagi array for the size

The bandpass antenna is a product of the *Swan Antenna Company, 646 N. Union St., Box 1122, Stockton CA 95201.*

Portable Checker Tests FET Gain, Leakage

The Model FT155 is an FET tester designed for easy use by technicians. Field-effect transistors, like vacuum tubes, cannot be checked out on a conventional transistor tester. The FET is measured like a cold vacuum tube and requires charts that

12V Power Transistors for 450 MHz FM

A chain of balanced-emitter rf power transistors is capable of providing 12W in the 450 MHz band with a 12V supply. The new transistors, 2N5644 through 2N5646, are intended for use as power amplifier stages of mobile transmitters in the UHF FM band. The 2N5646 family is supplied in the popular 3/8 in. ceramic stripline opposed-emitter package. Wide, low-inductance leads provide easy design and adjustment, especially in broadband circuitry.

An important feature of the new transistors is their balanced-emitter construction: Each unit is composed of many monolithic transistors in parallel, with a thin-film Nichrome resistor in series with each emitter. If current should increase in any one of these transistors, the rise in voltage across the emitter resistor will decrease base-to-emitter voltage, reducing the current flow. The equivalent parallel resistance of all the resistors is very low, hence does not cause significant degeneration. Because of the balanced-emitter construction, these transistors are very resistant to damage from mismatched loads or detuning. *Motorola Semiconductor Products Inc., Box 20924, Phoenix AZ 85036.*

The Motorola 2N5646 rf power transistor has an output of 12W in the 450 MHz band with a 12V supply. Balanced emitter construction makes device resistant to detuning and mismatching.

Semiconductor Book in the Printing

The just-released Motorola Semiconductor Data Book (Fourth Edition) provides specifications on all EIA-registered semiconductor devices, and complete data sheets on all discrete semiconductors manufactured by Motorola (3626 types). The 2160-page hard-bound and fully indexed book also includes useful selector guides, package and application information, and vital semiconductor statistics. *Motorola Semiconductor Products Inc., PO Box 20912, Phoenix AZ 85036.*

Magnetic Latching RF Relay

Development of a new single-pole, double-throw magnetic latching coaxial relay has been announced by Dow-Key. The relay, which measures approximately 2 x 2 x 3/4 in., will handle 50W CW or FM, 100W PEP at frequencies up to 1.2 GHz. The no-bounce latching feature of the new relay makes it especially suitable for satellite and other applications where power consumption is of critical importance. The maximum vswr is 1.3:1 at 12 GHz. Coil voltage is 26V (dc). *Dow-Key Co., Broomfield CO 80020.*

Scan Receiver has Lockout Feature

Among the first in a new series of 2 meter FM receivers that provide autoscanning, the Kris also contains switches that allow channels to be skipped over in the scanning process.

The autoscan receiver samples 7 channels, sequentially and continuously, and "locks on" whenever a signal appears on one of the 7 channels. The scan rate is 20 samples per second. Crystals are not included in the $149 price. *Kris, Inc., 1026B S. Washington Ave., Cedarburg WI 53012.*

5-Element Single-Band Beam Offers High Gain, Low SWR

The *"Classic 20"* is a 20 meter single-band beam featuring the Classic Feed System (Pat. No. 3419872). An improved electrical balance, "Balanced Capacitive Matching," combines with optimum spacing to provide maximum gain, increased bandwidth, and more efficient performance than other antennas of its class. The rugged construction typical of all Mosley beams is incorporated into the *Classic 20*: high-impact insulators and clamping blocks, aluminum tubing, and stainless steel hardware.

Specifications:

Power rated: 1 kW AM/CW; 2 kW PEP SSB
Forward gain: 9.8 dB (11.9 dB over isotropic source)
Front-to-back ratio: 20 dB
SWR: 1.5:1
Feedpoint impedance: 52Ω

The *Classic 20* is a product of *Mosley Electronics Inc., 4610 N. Lindbergh Blvd., Bridgeton MO 63042.*

Electronic Keyer has Multiple Functions

In addition to providing perfectly formed and spaced characters when used with a paddle or squeeze key, the EK-38 "Electronic Fist" provides semiautomatic keying with a straight key or a "bug" for use

on-the-air or as a code practice oscillator. Power supply, sidetone oscillator, and speaker are built into the small attractive cabinet. Sidetone pitch and volume controls are provided as well as momentary and locked TUNE switches. A jack is provided for an external manual standby key. *Curtis Electro Devices, Box 4090, Mountain View CA 94040.*

AN/ART-13 100-WATT XMTR
11 CHANNELS 2 to 18.1 Mc
200-1500 Kc

Collins Autotune Transmitter, extremely stable and suited for side band. Written up in QST Oct. issue, 1963. These are in boxes & crates as received from the Gov't & we will ship them out "as is" with no guarantee. They are supposed to be complete & with tubes. We are not even going to open the boxes and will simply stick a label on them and ship them out. We must make room for incoming material and our loss is your gain.
#ART-13 ..... $15.00

HAMMARLUND APC CAPS

Midget style, brand new, 4.5-100 mmfd.
3/$1.00 ..... 12/$3.50

APC GRAB BAG

Unused assortment of various sizes and styles. Thousands on hand & bargain priced.
5/$1.00 ..... 30/$5.00

TOROIDAL CORES

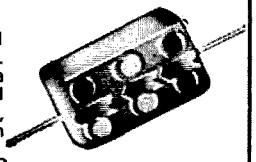
Insulated powdered iron core about the size of 25¢ piece. Very low inductance, hi-freq. Wind your own transistor xfmrs.
#A-70. . .5/$1.00 ..... 30/$5.00

PHOTOFLASH TRIGGER XFMR

Thordarson #22R44 brand new, produces 15KV pulse. With spec sheets.
#22R44. . .$1.75 each ..... 10/$15.00

RF FERRITE CORE CHOKE

Hi-permeability, ultra midget style, coated for moisture resistance, color coded. Used in xmtrs, receivers, converters, TV-peaking. Brand new, worth 40¢ each. Assortment of 1.8, 27.0, 330 uh. Pack of 30 $12.00 value.



#A-71. . .30/$1.00 ..... 180/$5.00

TRANSISTOR MOUNTING PADS

Round fibre glass insulating pads, used under 3 legged TO-5, TO-18, etc. Raises and insulates transistors from PC board. Permits longer leads to be used with less danger of heat destruction. Adds professional touch to finished circuits. Bag of 50 pre-drilled pads.
#A-3. . .50/$1.00 ..... 300/$5.00

SILVER MICAS

Misc. assortment of CM type small silver micas. Supply varies & will give a mix of available on-hand stock. Unused, long leads, standard codes stamped on each.

#A-4 . 30/$1.00. 180/$5.00

2 METER ARC-3

Just uncovered a batch of the famous ARC-3 rcvrs & xmtrs with all tubes. Range 100-156 mc, 8 xtl channels. Cheap way to get on 2 meters, CD nets, MARS nets, etc. With conversion details.
Rcvr $15/Xmtr $15 ..... Both for $25

Above equipment on hand, ready to ship. Terms net cash, f.o.b. Lynn, Mass. Many other unusual pieces of military surplus electronic equipment are described in our catalog.

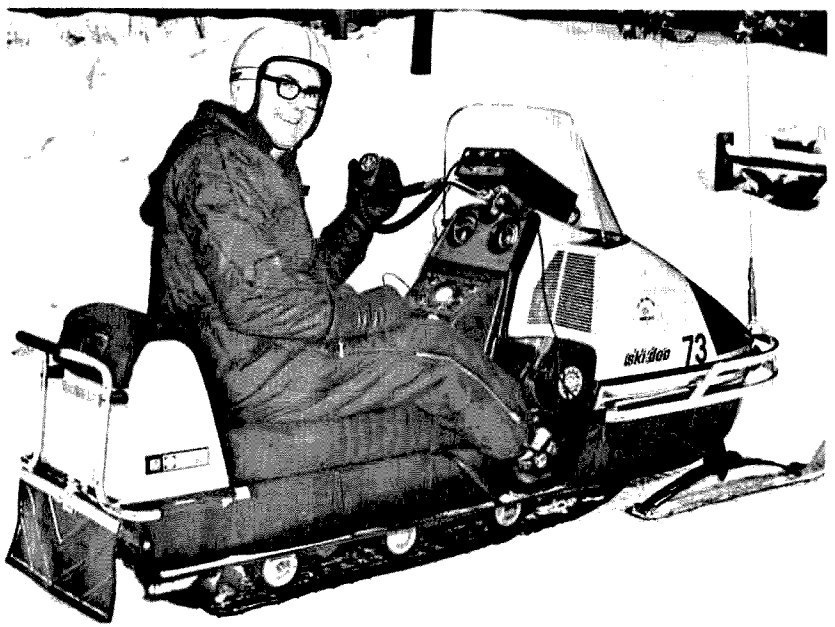
A bunch of people (listed at the left) worked far beyond the call of the almighty dollar to make this the biggest, best, most attractive issue of 73 yet published. They hope you notice. They are working on the Big April Special FM Repeater Issue which will carry the most complete and up-to-date listing of the over 300 amateur FM repeaters in the U.S. They solicit your help in getting interesting items for the Amateur News Page, the first ham newspaper of its kind. You're not on FM yet? You will be.

Amateur Radio News Page

Subbands Reallocated in FCC Action

Amendment of FCC Rules Adopted To Shift Frequencies and Emissions In the Amateur Radio Service



Amendment of Section 97.61 (a) of the Rules shifting frequencies and emissions in the Amateur Radio Service to the subband where A-1 emission is exclusively permitted from the 147.9—148 MHz band to the 144.0—144.1 MHz band; and shifting the subband where F-1 emission is permitted from the 29.0—29.7 MHz band to the 28.0—28.5 MHz band, has been adopted by the Commission, effective March 2, 1970 (Docket 18508, RM-886, RM-950).

The amendments were originally requested by the American Radio Relay League (ARRL). A Notice of Proposed Rule Making in the matter was released on April 3, 1969, (FCC 69-313), inviting interested persons to file comments on or before June 11, 1969, and reply comments on or before June 23, 1969.

Cl

Comments in support of the changes were filed by the ARRL, the Electronic Industries Association (EIA), Central States VHF Society (Central), and Forrest A. Bartlett (W6OWP). A comment filed by Donald R. Nelsch (K8EIW) supported adoption of the proposal in RM-886, but requested F-4 emission to be included in the 144.1 to 148.0 MHz frequency band. A comment filed by Howard McCall (W8TNF) was the only one which opposed adoption of the proposal in RM-950. No reply comments were filed.

SNOWMOBILE "MOBILE"... a first?

Bill Loeffler W1PFA Salem N.H. combines ham radio with the new popular sport snowmobiling. With a Galaxy FM 210 and Antenna Specialists 2 meter gain

CD Group Goes 2 Meters - FM

Bill Loeffler, W1PFA radio officer for the town of Salem, N.H. recently announced the RACES section of Civil Defense has planned to purchase 10 Galaxy FM 210 units of local communications. Recent tests made with the units proved the town to be neatly covered with mobile operation to base station with no blackout area whatever. Don Alexander W1UFK and Tony Coco K1ILB, communications officers for the town, feel that channelized operation on the 2 meter FM band, will greatly advance the local operation. Salem is expected to be the first RACES operation in New Hampshire to go FM.

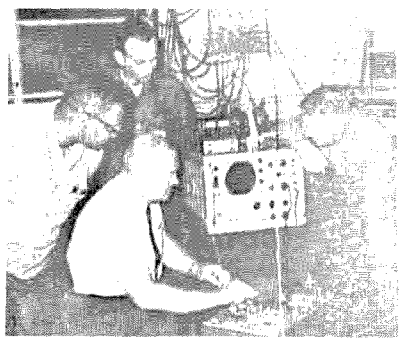
YA Club Formed, Award Offered

Group standardizes prefixes

Since there is no licensing authority in Afghanistan, amateur operation in that country has been somewhat confused in the past. Amateurs have mere-

In its comments, ARRL pointed out that the 144.0—146 MHz band was assigned to the Amateur Radio Service on a world-wide basis, and that the 146.0—148.0 Mhz band is authorized to the Amateur Radio Service in Regions Two (Western Hemisphere) and Three (Southern Asia and Oceania), and to the fixed and mobile services in Region One (Europe, Africa, and Northern Asia); that while the 144.0—146.0 MHz band is specifically authorized for amateur satellite operation, the present 147.9—148.0 MHz, reserved for A-1 emission, cannot be used in Region One. The proposed 144.0—144.1 MHz band may, however, be used world-wide. Canada also has set aside 144.0—144.1 MHz for A-1 only operation.

The Commission said it believes that "clearing a portion of the 144—146 MHz band is desirable for continued experimentation in space techniques by amateurs."



Central commented that, although it supported the proposal, the Commission was not going far enough. It stated that "the assignment of the first 100 kHz of the 144 MHz Amateur band to A-1 emission is at best a stop gap measure . . . " and that additional protection of experimentation may be required in the future. The Commission said, however, that the evidence submitted by Central is "insufficient to persuade us that a larger subband is needed and should be authorized at this time."

In reference to the suggestion made by Mr. Nelsch that F-4 emission be included in the 144.1—148.0 MHz amateur band because of the availability of facsimile equipment of commercial quality, the Commission said that this request is beyond the scope of this proceeding. It added, however, that the matter is the subject of a separate petition for rule making (RM-1429) filed by James L. Turrin (WA8DCE) and would be considered when that petition comes before it.

C

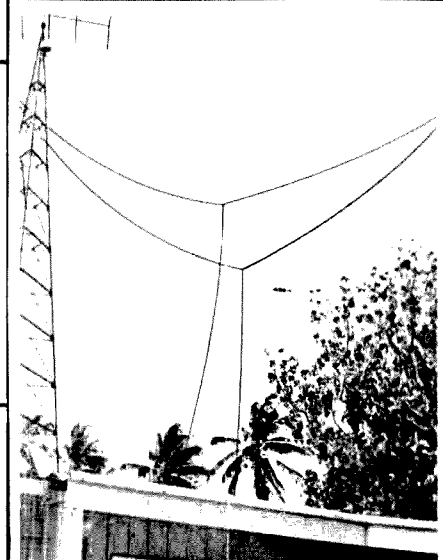
Howard McCall told the Commission that he disagreed with the proposal in RM-950 to relocate F-1 emission in the 28.0—28 MHz frequency band because it would result in a loss of 200 kHz for this type of transmission. Although the proposed relocation would result in a reduction of 20 kHz of bandwidth available for F-1 emission, the Commission said it believes this loss is "not extensive and is outweighed by the advantage of moving radioteleprinter emission (F-1) into the CW portion of the 28 MHz band."

Finally, the Commission stated that it believed that the shift in frequencies would not affect the operation of its users significantly.

FUCHU AS, Japan — Members of the Far East Auxiliary Radio League in Japan receive a demonstration of manufacturer's performance specifications versus actual performance in electronic equipment by Mark Radke (seated) of the U.S. Army Depot Command, Japan. Watching the demonstration are (from Left) Skip Brady, KA2SB/WB6RBI, Ed Frazier, KA2ZD/WA0ZZD, and Bill Ross, KA2DK/K5LLK, league president. The league is composed of U.S. military personnel in Japan with an interest in amateur radio. The group promotes activities of KA stations in Japan and fosters goodwill in the Far East and throughout the world through the medium of amateur radio.

Allied has free classes

Allied Radio Corporation will begin its annual Novice amateur radio license course on January 19, at the main Allied store, 100 N. Western Ave., Chicago.



The free 14-week code and theory course will meet each Monday evening to help prepare would-be hams to take the Novice FCC license examination. The course will be taught by one of Allied's staff of licensed radio amateurs, with the major emphasis placed on learning the code.

antenna mounted on front of Ski Doo, Bill works into the W1ALE repeater at Concord, N.H. Power for the rig is taken from the cigarette lighter socket on Ski Doo. The snowmobile is a Bombardier Ski Doo Nordic 640E. Bill is also a member of the Salem, N.H. S-Ki-Mos snowmobile club. The 73 on front of the 'mobile is Bill's registration number in the Salem S-Ki-Mos club; there are 85 members.

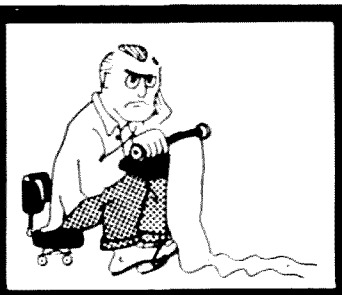
W1TNO (Ted) in Concord, N.H. reported that he worked W1PFA/snowmobile in Salem, N.H. in late January. Bill was out with the local snowmobile club, with some 90 snowmobiles, running a test to check on the emergency use of FM via the repeater. The test worked perfectly, easily turning on the W1ALE repeater in Concord, some 40 miles away. Is this the first repeater FM operation from a snowmobile?

FCC Nails Ham for "Fraud"

In a public notice issued on January 16, 1970, the FCCrevoked the license of Herbert L. Rippe W8DE. According to the report, Rippe had obtained his two-letter call by "fraudulent" means, in violation of Section 97.129 of Amateur Rules and Regulations, Part 97. His revocation was made effective as of February 16.

ly brought in their equipment, set it up, picked out a call they liked, and gone on the air, hoping that no one would get upset in the government.

A little order is appearing out of the chaos now with the formal organization of the Camel Drivers Radio Club, organized by YA5RG. The country has been broken up into nine prefix districts, and the club will endeavor to get all ops to abide by them. This may be helpful and will certainly go a long way toward preventing one op from coming to Kabul and using ten different number prefixes in order to generate more DX activity, giving the impression that he is actually moving around the country.



The club is offering the *Afghanistan Radio Award* to all amateurs and SWLs of the world. Contacts must be confirmed on at least two amateur bands and six contacts are required for YA amateurs, four for Asian amateurs (except YA), three for Europeans, and two for the rest of the world. Send QSLs and 10 IRCs (or one dollar), contacts from 1966 on count, to CDRC, Box 279, Kabul, Afghanistan. Send an extra dollar for airmail return.

VK9KY ACTIVE FROM COCOS KEELING ISLE

One of the more remote spots in the world is Cocos Keeling Island, off the coast of Australia and south of Sumatra. The only active station on this island is VK9KY, operated by Ken Young, who is living on Cocos running the Ionospheric Prediction Service station. The tower is used for the vertical sounding of the ionosphere and the fixed beam on top of the tower is pointed at Sydney for the weekly reports to the home office.

The dipoles are used for contacts on 15 and 20 meters and are broadside to Europe, thus holding the signal down a bit toward the States. Ken is planning on putting up a groundplane, and may even be able to swing a wire beam in a stateside direction. There are, of course, no materials available on the island for building even a simple regular beam.

If you might be able to help Ken out with antenna materials, his address is Box 31, Cocos (Keeling), Indian Ocean via Perth, Australia. QSL to his manager VK2SG. He often can be worked on 20 meters around 1200Z, sideband. Stamp collectors will treasure the beautiful bird stamps from Cocos.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

Since I am sure that many readers must be pretty sick of reading about the ARRL in my editorials, I will ignore them completely this month except for a short answer to a letter.

The letter (from Paul Crilly WA1IND, 15 Rosewood Drive, Simsbury, CT) is quite critical of me for having bad things to say about the ARRL, which he considers a fine organization which has helped hams in countless ways. He feels that the amateurs are enthusiastic about incentive licensing and that I am afraid of progress and improvement of the quality of amateurs.

You might think, from some of my mail, that I have written editorials saying that the ARRL is run by a bunch of crooks, headed by Captain Klutz, a chap whose morals would make the Mafia blush and whose intelligence would hardly qualify him for admission to the Crotched Mountain Home for the Mentally Retarded. No matter what I may personally think, I have not written anything like that.

The ARRL was started by Hiram Percy Maxim, a genius, the son of a genius, and the grandson of a genius. It took genius to get something like the ARRL going. When Maxim died there was the usual fight for control by those of less than genius talent. Some day someone will write an honest history of the ups and downs of the ARRL, but so far all we have seen are self-congratulatory rewrites of history.

Though the League has fallen into the hands of those of less than genius calibre, the organization continues to provide many very valuable services to the amateurs it was founded to serve. Few of them, unfortunately, are completely above criticism. We have not historically seen much improvement in ARRL programs until the tide of public opinion has forced changes. In connection with this you might note that the voice of 73 is the only one not stilled by fearful publishers. I won't list the manufacturers who withhold their advertising from 73 in an effort to force us to run bland editorials, but they are large and well known, and conspicuous in their absence from the magazine.

Perhaps I am deluding myself, but I can't recall running into a fervently anti-Wayne Green amateur that has read many of my editorials. When I talk with them I find that they are mad at me for things they have heard that I have written, not for what I have actually written.

Though I think of myself as a conservative, many readers seem to feel that I am a liberal. My reaction to incentive licensing is, I think, conservative. I feel that the ARRL management should have consulted the membership before petitioning the FCC for the rules change and I also feel that the whole idea would have been infinitely better if additional privileges had been offered for advancement rather than the punitive taking away of privileges from those who chose not to advance. It is basically the concept of using the stick or the carrot, with me favoring the carrot and ARRL the stick. You get more flies with honey than with vinegar.

A recent poll asked 73 readers if they thought amateur radio should have a lobby in Washington. The response was almost 100% in favor, yet the probability of anything like this happening seems remote. Why? The ARRL management certainly recognizes that such a lobby is not only needed, but is of critical importance to our future, yet they continue to do everything in their power to keep the directors from bringing it up at Board meetings. How come? As one of the HQ small fry explained it to me, the management feels that if a lobby is started in Washington there will be no way to keep the headquarters from eventually being moved to Washington, since HQ would have to follow the action. They don't want to move. They have nice houses, friends, and are comfortable in Newington where they are. As long as they can keep the Washington lobby cooled they can live on undisturbed.

But what of amateur radio, you ask? Since few of the ARRL management have been active amateurs in many years it is not really surprising at their seeming lack of emotional involvement with the hobby. I get a strong feeling that this is strictly a business matter with them and nothing more. They try and have business interfere with their personal lives as little as possible.

You might contrast that with the involvement at 73. Mike, Ken and I spend a good part of our waking hours working at 73 (or hamming), seven days a week. You will seldom not find at least one of us on tap by 6a.m., and the work goes on into the night when deadlines demand.

No matter how much good the ARRL does, there are bound to be some bad things and if these are not discussed and exposed, how can they be improved? Bad flourishes in secrecy and dies in the open.

When I write about the ARRL I try and differentiate *between* the 75,000 members (including me) and the management running the show at Newington. Most of the bad things that are going on are attributable to this small group, not the members. Now, do you feel that there is anything wrong about discussing the problems we are having with what can best be described as amateur radio's unelected "government?" Am I being picayune when I criticize this group?

Down through the years I have spoken out many times in my editorials in support of many of the programs run by the League. It seems to me that it would be redundant to do this in every editorial. For the most part readers of this editorial are the same readers that have endured dozens or even hundreds of my past editorials, so I try not to repeat myself too often.

When I first started in amateur radio I, too, used W1AW for code practice. Of course there were not nearly as many alternatives in those days. Few amateurs sent at less than 13 per on the air, there were no Novices yet, and about the only choice was an Instructograph tape machine or expensive 78 rpm records. Now, with inexpensive tapes and LP records available, plus thousands of Novices on the air, the need for W1AW code practice is probably not as dramatic as it was 35 years ago, but thousands of would-be amateurs still tune in W1AW every year for the service.

There has been considerable criticism recently of the W1AW practice of just coming on and sending code or bulletins with no regard for those already on the frequency, but I suspect this may be due to one tactless operator rather than headquarters policy.

The short-haul limitations of amateur radio were responsible for the beginnings of the American Radio Relay League, since relaying was the only way to cover longer distances before the short waves were discovered. This still lives on in the dozens of traffic nets spread out around the country, an activity that is basic to the ARRL. Since I have never been an enthusiastic CW operator, my own experiences with traffic handling have all been on phone or RTTY, but I certainly never put down the fellows that love traffic handling.

Are We Afraid of Progress?

Since 73 is normally months or years ahead of the other amateur magazines in bringing new technical developments to the amateurs, our marks in "progress" should be okay. The high density of technical and construction articles in 73 should acquit me on "improvement of quality of amateurs."

Might I point out, too, that only 73 has run a technical study course to help you upgrade your license. Are we doing more to help improve the quality of amateurs than the ARRL? Speaking of which, whether we like incentive licensing or not, it doesn't seem about to go away, so perhaps it is time to sit down and start plugging through our Extra Class series.

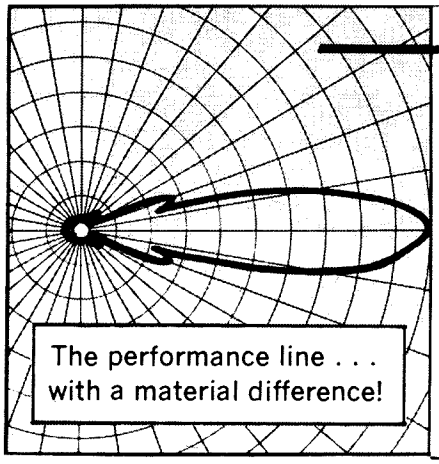
You know, I suspect that if Maxim were running ARRL we would be good friends and working together instead of the present system whereby HQ seems to be doing everything in its power to undercut 73 and ignoring as long as possible the needs and wishes of the members.

ARRL November Board Meeting

Several letters have been received complaining about the directors meeting, pointing out that they spent thousands of dollars getting together, only to discuss trivia and to ignore the major problems facing amateur radio. Since I have decided not to be critical of the ARRL in any way in this editorial, I shall say nothing about the Board meeting except that those of you who have access to the January QST will find it fascinating to read the detailed minutes of this historic Board meeting starting on page 75.

Improvement?

Now, didn't you like that editorial much better than those rotten ones where I am critical of the League? If this turns out to be popular I may write an editorial avoiding critical comments on our esteemed competitors down in New York.



New Year's Present for Wayne

A daughter was born to my wife Lin just hours before the new year. Name: Sage Anetta Green. Your wives may be interested that we used the bubble all through pregnancy and during labor. The long term results are to be seen, but labor was quite easy and the birth was quick. The bubble, if you are not familiar with it, was invented in South Africa recently and provides a way for extra oxygen to get to the baby's brain during pregnancy, theoretically helping the brain to develop better and faster than without the oxygen. It also helps greatly during birth, providing the extra oxygen at this critical time, and easing delivery markedly.

Million Dollar TVI Suit Dies

We checked with Grid W4GJO and found that the TVI suit against him has been dropped. I am sure that the impressive backing Grid got from interested amateurs who sent donations to help with the fight had a lot to do with the dropping of this suit. If you have any illusions about what a great fight ARRL puts up for amateurs that get into serious legal difficulties such as this one, difficulties that could well turn into a nightmare for all amateurs if not fought to the bitter end, then just drop in at the Ham Shack in Sarasota and talk with Grid. You will find that not one penny of the thousands of dollars Grid spent on his fight came from the League.

Legal battles like this one might never get started if the complainant knew that the amateur he was suing would be supported financially all the way to the Supreme Court by the ARRL. The Institute of Amateur Radio did furnish cash for

helping amateurs in legal difficulties, because one of its tenets was the belief that one ham's fight is amateur radio's fight. If the Institute could do this, so can the ARRL. The next time an ARRL director talks to your club, ask him about this . . .or write to him and ask. Get that ball rolling. Could you personally stand the $5000 to $50,000 that a suit like this can cost?

Band Occupancy

A recent study of the occupancy of our major bands during high density hours showed that the Extra Class segments are getting a lot more use than many of the underprivileged think. The survey, run by ARRL, and using about 100 amateurs as observers, might be more meaningful if it also covered medium and low density hours when the level of interference does not keep as many operators inactive that might otherwise be on the air. I suspect that the General bands fill up first, then the Advanced, and lastly the Extra. Full is full, and when all are full, then all are being equally used . . .right?

Free Advertising

Although we realized that 73 is very popular in colleges all around the country, we are flabbergasted at the strength of the student devotion. You may note, as we have, that pictures of college students with the "73" emblem on them are appearing in papers everywhere!

VOX POP

Monthly Report of Activities on our Bands

There are a lot of interesting things going on in our bands that are all too poorly reported. Starting in April we would like to devote some space in 73 to reports of doings on the bands, with a separate section devoted to each amateur band and mode. Reports should be in our hands by the tenth of the month.

What's interesting? That depends upon the band, of course. Our 160m readers would like to know about DX tests, activities in rarer spots, nets, new counties activated, and any other organized activities on that band. Heretofore, there has been no good place to report something like this or any way to organize special interest nets, etc.

On 80m we have lots doing with the traffic nets, plenty of interesting activities in the Novice band, plus DX. I don't have in mind anything like the QST Station Activities column which lists who bought what new equipment and who passed along how many messages. But if TR8MC shows up on 3565 now and then, I think a lot of fellows would like to know about it. Up in the phone band there are a number of interesting nets that could well use some publicity now and then. When the Eyebank Net gets an eyeball to the right spot at the right time, that's news. When KR6AJ comes through regularly on 3808, that's news. When DX-minded ops manage to get the DX stations to tune up into the band for them, that's news. When a DXpedition is going to give the 75m gang a workout, everyone would like to know about it. I'm sure that the RTTY group on 80 has some news now and then that they would like to pass along...etc.

DX chasers will want to know the frequency, GMT, and QSL manager of rarer DX. We will pass it along, complete with the call of the fellow reporting the news.

On the higher bands I am sure that many of us want to know what is happening around the country on FM, TV, SSTV, moonbounce, satellites, meteor scatter, and other specialized branches of the hobby.

Modulated Vibrator Hash

AN EDITORIAL BY K6MVH KEN SESSIONS, JR.

In the past several weeks I have been doing a great deal of soul searching. My position as editor of 73 requires that I give full and adequate coverage – nonpreferentially – to all facets of amateur radio. Yet my personal involvement has been almost entirely with VHF FM and repeaters. As somewhat of a prominent figure in FM circles, I feel that I am under a special obligation to make 73 take up where FM Magazine left off. On the other hand, 73 has always represented the DX'er, the sidebander, the CW enthusiast.

So you see the embryo of a dilemma that has cost me more than just a few hours of sleep. The problem became even more dramatic when Mike Van Den Branden, former publisher of FM, joined 73. With the entire *staff* of the now-defunct FM journal at 73, a commitment to heavy FM/repeater coverage seemed even more necessary.

Good ol' Father Green gave me the answer. He came into my office, closed the door; and said something like, "Okay, it can't be all that serious ... We've got Blue Cross, your rent's paid up, and we all love you. So what's on your mind?"

I told him that I felt a special obligation – and need – to publish circuits, stories, features and news about the fast-moving and ever-changing field of FM and repeaters, but I couldn't justify slighting the other amateur modes in the process.

There would be no need to slight the other aspects of radio, he told me. And he solved my whole problem without so much as a wrinkled eyebrow. All we have to do, he said, is include more FM articles each month than the Journal did – and do it without sacrificing any of our regular content.

Simple solution ... just make 73 a little bit thicker. So that's what we did! Is that any way to run a magazine? You bet it is!

RM–1542

One year ago last January, FM Magazine published a tentative petition with regard to repeater rulemaking, and repeater owners were invited to submit comments and recommendations for changes. The purpose was to present a comprehensive rulemaking proposal to the FCC that reflected the combined ideas of all active FM people.

Shortly after the petition was published, suggestions began pouring into the editorial office. Then the League decided to take a hand, too. With the FM'ers going all out on the one side to get a meaningful set of repeater rules, the ARRL went off in another direction by appointing a staff of seven men to study the requirements of repeaters so that the League itself could make a recommendation to the FCC.

The League ignored the efforts already under way, and chose instead to make up its committee of staunch League members, *nearly half of whom have not participated at all* in the actions of the rulemaking group. Because of the apathy of part of the League's committee, some of the more conscientious members have become quite piqued, and are looking for a reorganization. Several members of the committee have not participated in any of the group functions, a fact that has stirred considerable controversy among the members.

One member of the League's advisory group has taken a more than passing interest in the problems, and is trying to pull the group out of its slump by actively campaigning for a set of proposed rules drafted as a result of recommendations based on comments from repeater organizations (particularly the California Amateur Relay Council) and, presumably, the original set of recommendations published in FM Magazine. That man is John J. O'Brien W6GDO, who is serving the dual role of ARRL repeater advisory committeeman and FM editor of Ham Radio. (I didn't think it was legal, since League President Denniston told me personally a year ago that I was ineligible for the committee because of my former association with FM Magazine.)

At any rate, O'Brien's rules have been reviewed by a number of active repeater groups, but they have not been adopted by the advisory committee. His recommendations are sketchy, but they appear sound and workable. The unfortunate thing is that his proposal is a long, long way from home. The advisory group must agree to accept it, following which it must be sold to League officials in Newington.

Meanwhile, hundreds of active FM'ers responded to the call for suggestions published originally in FM. These recommendations have been sifted and integrated, reworked and redrafted. Finally, one full year after the first draft was published, the final non-ARRL petition was submitted to the FCC. I personally submitted the petition, which bears identification number RM-1542, and will attest to the fact that it contains the ideas, recommendations, and constraints recommended by the collective body of active FM'ers.

In case you're wondering what was in RM-1542, the essentials are listed in last month's "Modulated Vibrator Hash." If you're an FM'er and you *care* about recognition, licensing, and modifying the restrictions of repeaters, write the FCC now, and recommend quick action on RM-1542.

VIRGO

Probably every ham goes through the "cute phonetics" stage at some point early in his career. I started looking around frantically for something clever back in 1956 when I had a column in *Western Radio Amateur*, a west coast publication published by Don Williamson W6JRE. I wanted something snappy, like "Never Say Die," but my call, unfortunately, didn't end with "NSD." Quite coincidentally, during a late night QSO with my half converted military surplus transceiver, someone—I don't even remember who—commented that my signal was so raunchy it sounded as if I were modulating vibrator hash. The column title was born for me. It was something I was never crazy about, but it seemed reasonably apropos, so it stuck . . . through several amateur publications.

It wasn't until after I got to 73 and Wayne introduced me to someone as "Mr. Virgo himself," that I became totally disenchanted with the vibrator hash bit. After overcoming my initial depression resulting from the fact that I hadn't thought of the Zodiac tie-in myself, I elected to retire the tired "Hash" for good. From now on, I'll be Mr. Virgo Himself.

SPECIAL PEOPLE

Sometimes I think somebody ought to do something special for the "special people" in the ham radio business. The special people are those who manufacture and sell the gear we use. I've been around long enough to know that no one gets rich doing business with hams. Yet, as hams, we demand more of these fine folks than we'd expect of Sears or Montgomery Ward— and we get it!

I've lost track of the times I've pestered poor old Ted W6UOU at Henry Radio in Los Angeles. This rig didn't work right, or a part was missing from that antenna kit. Never a complaint or question. Always, the Henry people would make sure I was satisfied before I left the store.

My dad (Ken Sr., K6MQB) *really* puts them through their paces. He's an active ham with interests that change with the seasons. And he lives no more than a few blocks from Henry's L.A. store. He goes from 6 meters to 75...then he gets a yen for 15 and 20 sideband...it's beams and towers and quads...something for the shack, then something for the mobile. And each change means a trip to Henry, to check in the old gear and check out the new. I'm sure half the stuff he carts out of Henry's never even gets turned on. Everybody there pretty much knows him by name, and I suspect they don't even bother to write up the paper on half his purchases, knowing he'll be back in a week or two to trade it all in.

But they're good sports at Henry's—like they are at a lot of other stores where you and I and my dad buy gear. They may flinch when they see us walk in the door, but they don't show it, bless 'em.

...K6MVH FM

I spent this evening on the air, working old friends whom I haven't contacted in months. Now my antenna situation is cleared up I've been making up for all the time I've been struggling with limited means . . . dipoles mainly. After three or four contacts I got a call from a fellow in a nearby town. He has one of those shiny new two-letter calls, but he used to be an ordinary, garden variety K2 like the rest of us plain peasants.

"I've been reading your stuff in 73," he began. His tone was a little patronizing, as though he were at least the book reviewer of the Sunday Times. "It's pretty good," he says, "but I'd sure like to talk to you about one rock you pulled. I disagree with you completely on that one, Kid. I'm sure you didn't mean it the way it sounded, Dave."

This sounded serious and it piqued my curiosity. I asked him what part of the article he meant, but he demurred, saying he'd rather not discuss it on the air. He indicated that he would call me on the telephone, but did not wish to talk about it at present. I told him that I didn't mind his taking issue with what I had written...after all, the objective of a column like mine is to provoke thought and discussion. I never intended to write the sort of mealy-mouthed ambiguity with which everyone would automatically agree. I did not set out writing for 73 merely in order to put down on paper all those things which would justify widely held opinions, merely to bolster them. I added that sometimes an opposite opinion could serve to strengthen a reader's precepts and ideas, thus could serve two opposing viewpoints.

This particular column did not carry anything too terribly controversial, for I was merely trying to show how some topics might be handled innocuously. To be honest, the piece was written more or less jocularly, with no really serious objective in mind other than to illustrate the folly of outlawing particular subjects on the ground that they are in and of themselves unsavory and unwholesome. I thought to myself, "Perhaps he has taken exception to the part about religion. Many persons have rather thin skins on this subject, and consider it improper to discuss at all." When I asked him about this he said that it was not the part about religion.

By this time I was puzzled, and started pumping him. But he would not say anything more than he had already said. He simply changed the subject and would not "drop the other shoe."

Then I began to feel the pangs of annoyance. Why should I have to listen to what he had to say in the first place? He's not particularly qualified to do more than express an opinion, not being any sort of an expert, so far as I know. I'd gone over the column mentally in order to puzzle out what could have bugged him, but couldn't imagine what it was...unless it was the part about the pig farmer in Secaucus who ran for the Presidency so often. In my article I alleged that he could not have done worse than some of our recent Presidents, governors, and mayors. Maybe it was that apparent irreverence that annoyed him.

Now that I think of it, I tend to agree with him. I too am annoyed. I'm annoyed at myself for not saying that the pig farmer would have done better than some of our recent leaders!

• • •

The other afternoon the educational TV station programmed the new film produced and directed by Dave Bell W6BVN, entitled *The Ham's Wide World*. I was very much impressed with it, and must confess that it turned out a darned sight better than I thought it would. I don't wish to sound patronizing about it, for it needs no qualifying preface or apologetic foreword to prepare the way for some amateurish or unprofessional home-movie type stuff . . . it is a finished product in every sense of the term.

I was a little irked about its limiting the activities shown to those which are ARRL conmected, thus making *non*persons of hams who don't belong to the League. While it is perfectly reasonable for ARRL to depict League activities in any film which it sponsors, it should not be forgotten or overlooked that there are thousands of amateurs, engaged in helpful spheres of hamming, thoroughly in keeping with the spirit of dedication to the public good. This is only a minor point, however, and can be dismissed in view of the overall value of the film.

The best thing about it, to me, is that there are entertainment values in it, which have been all too lacking in its predecessors. Most of the earlier efforts were marred by a certain quality of dreariness. The voice of K4LIB, Arthur Godfrey, is so familiar that any audience can identify with it readily, and he was probably the best possible

choice as narrator.

You will probably have an opportunity to see the film since it has been accepted by National Educational Television for showing on all educational channels for the next couple of years. I recommend that you take the time to view it, for it is surely an excellent piece of material which should help to promote good relations between amateur radio and the public.

• • •

I've got to level with you about something that's been bothering me since I started writing LEAKY LINES. There have been letters and phone calls ... even visits, all expressing satisfaction and enthusiasm with my position concerning ARRL's extraordinary lack of responsiveness on certain issues recently.

When this sort of response occurs, It is natural to assume that it will be followed by some sort of action. Such a response signifies a readiness to roll up the sleeves and do a job. It denotes agreeement that the League's only chance to become, in fact, what it claims to be, lies in the direction of increased membership activity.

But what have they done? Precisely nothing! That is, all excepting the members of the Atlantic Division, who elected W3EPC, who may just turn out to be the best director in years.

How are the rest of us supposed to match the Atlantic Division? If the only action a member can take is to vote in an election, a lot of people are going to be cooling their heels for a long time. If a member has to suffer the leadership to do anything it wishes, pending the only date on which he can register disapproval, election day, it seems unlikely that anything will be accomplished to effect any improvements. What are we supposed to do until then?

I think the time has come to think realistically about some structural changes in the League machinery. Is it possible, I wonder, to restructure the League, so as to be able to recall or dismiss persons who are not doing, or show no signs of willingness to be doing, the job they were elected to do? In Britain, whenever there is any sort of disagreement in which the opposing forces are unalterably unwilling to come to a position of compromise, they hold a "vote of confidence," in which the popular support and rectitude of the "ins" is tested in a general election. If the Prime Minister cannot muster support for his program, the other party takes over the reins of government, and names a new cabinet. In this way, although the parties may face periodic crises, the body politic is constantly able to renew and refresh itself, secure in the knowledge that the will of the constituency is being served and gratified.

Perhaps we could establish some similar organizational arrangement in the American Radio Relay League. It would certainly be a distinct novelty to know that the democratic (small d) institution of a two-party system, which works so well for our nation, would guarantee a more equitable situation in the ARRL.

Doubtless, this type of change would result in one thing, at least. It would compel every functionary desirous of retaining his post to pay some heed to the membership, lest he get "dumped." If they did not like what he was doing, they would simply hold an election, and the guy would either shape up or ship out.

I've always admired the British. The main reason, I think, is because of this extraordinary tremendous concept of government, geared and gaited for the benefit of the governed, rather than those who govern. Good system, that.

Till next time, 73
... K2AGZ

LETTERS

Leaky Lines Feedback

In regard to the Leaky Lines editorial, I found it one of the most fascinating ham radio articles that I have ever read. I saw thru that bunch of ARRL clowns way back in the 50's. I sure go along with your ideas that the commission believes the ARRL is a spokesman for all of us hams, and I fully intend to tell them that I for one am not a fond member of the ARRL; further, I know hundreds of others who feel the same way.

Kenneth Mahoney K6OPG
455 41st Ave.
San Francisco CA 94121

I think that Dave Mann's ideas are very close to the truth...but I sometimes wonder if the mass of your readers are as fully committed to amateur radio. What I'm trying to say is that I feel that your articles and critiques are causing people to think, and most people don't like to think! If I'm wrong, please correct me.

Neil Johnson W2OLU

With reference to Dave Mann's "editorial" (73, February 1970) about QRM from W1AW, I would like to point out to your readers one example of the faulty reasoning found so often in your magazine. It is true that W1AW is just an amateur station, but unlike any other club station, it represents nearly 100,000 amateurs, worldwide. As such, it has special permission to operate transmitters on seven bands concurrently. As it would be impossible to check all frequencies just before transmitting–and we know that such checks are not always accurate, anyway– I would suggest that Mr. Mann's two friends should step aside graciously in the interests of the thousands.

Al Taylor WB4CTY
5722 1st St. S
Arlington VA

I have just received and read most of February 1970 issue. As I have received and read the first issue and all issues since, I must agree the Feb 1970 issue is one of the greaters. There are numerous articles in this issue and I am glad to see that not only both sides, but most sides are represented.

I must take issue with your Leaky Lines editorial by Dave Mann. It is such articles that have brought much of the things we are not proud of in ham radio today. He says that most all technicians got their licenses by fraud. Who is responsible for this, if true? Certainly not the Tech. Why not call all of the Generals or higher in that give these tests and ask them if the Tech. has a valid license, that they signed their names under oath.

It is a sorry thing that many advanced persons today hate to see anyone less gifted get anything or anywhere. I know of many hams that would rather see a piece of Novice equipment that had gathered dust for years remain so than to help some poor kid trying to get on the Novice band and give him something that will otherwise never be used.

Harold D. Mohr K8ZHZ
5670 Taylor Road
Gahanna OH

I find that Leaky Lines stuff on said-to-be-taboo topics not very interesting in a ham magazine. I am interested in the subjects all right, but not in a magazine that I regard as a technical gold mine. Speaking for myself, I have never hesitated to discuss anything over the air, and have found plenty of other hams ready to take part.

Bob Eldridge VE7BS
8386 McGregor Avenue
Burnaby 1, B. C.

Drumodulation?

Enjoyed the January 1970 issue immensely, especially the article on SSB, AM–FM Modulator by Bill Hayes. Seems though that this article should have been in the April issue. Would like to suggest another method to obtain the same results without using an oil drum. First, the trunk lid should be properly grounded to the car body. Silver-plated finger stock should be fine for this job. Next mount a 10 in. piece of heating duct to the bottom of the trunk. The cavity could then be tuned by banging on the trunk lid with a sledgehammer.

Wallace WA8OXR
5696 Williamson Ave.
Dearborn MI

You have got to be kidding! In the "SSB AM–FM Modulation System" article, Jan 70, F9 is not kosher for ham use.

What he has got there is most probably F9– depending on how he modulates the subcarrin, either AM–FM or FM–FM as in telemetry and all those Muzak-type SCA systems on broadcast FM. Minimum bandwidth of the signal must be in the subcarrin frequencies; in this case 35 kHz deviation, plus bandwidth of the Subcarrier modulation. Not such a good idea except for the wide-open spaces of two or up. Howsomever, the article rates a nod for the idea on cavities. The idea of trying a 55 gal drum hadn't struck me–trying for a low cost Magic Tee for a one-antenna 2 meter FM repeater. A drum might work!

Fritz Hervey WB4MSJ
Rt. 1 Indian Trial NC

Comparison

I received my issue of 73 which was excellent as always. I also picked up a copy of CQ at the newstand and this is what I noticed.

Number of articles in 73: 28 technical articles not counting the excellent editorials.

Number of articles in CQ: 9 and these were not all technical articles. Strange thing too about these 9 articles: 5 were by the same two authors, giving me the impression that CQ is hard up for suitable articles and good authors. This is bad enough but the editorials in CQ are all noncommittal and don't state a positive point. CQ is just

Ham Lobby

You undoubtedly saw the article (on spectrum grabbing) in the December 5th Wall Street Journal. This publicity certainly points up dramatically the need for a PR bureau and lobby for radio amateurs.

Everett T. Plumer Wb6VVT
1244 Sixth Street
Santa Monica CA

The article, "Spectrum Scramble — Airwave Jam Worsens As More Radio Users Demand Frequencies" backed up the editorials that I have been writing about the vital importance of our having a lobby in Washington, yet the ear in Newington seems to be as deaf as ever, and nothing else much seems to be taking shape. . . . Wayne

1984

Being relatively a newcomer to the ranks of radio amateur hamdom, having obtained my license only a year ago, I have carefully studied the situation which exists in the amateur world before plunging in with both feet. Years ago while yet in high-school, I had sensed something in regards to the ARRL which at that time I could not quite ascertain the nature of. In your battle against the undemocratic nature and scope of this organization, I believe I have been able to pinpoint the factor which gave rise to a "queasy" feeling earlier and remains with me to this day whenever confronted with this organization. In its manner of operation it resembles some of the radio societies in the Red fascist countries. It seems to serve the interests of "Big Brother" far more actively than the rights of the ham. But the, why shouldn't it *if it was set up by Big Brother* for the sole purpose of keeping control of radio enthusiasts? Instead of trying to instill democratic concepts into an organization which because of its nature can only reject them, would it not be far wiser to organize a new ham organization along the lines of the NRA, AOPA etc? Any new movement though, established while a prior despotic group is still in power, must have as a focusing point a published medium which breathes life and spirit into the soul of the new organization.

Tailored Callsign

When I write to you, it is primarily to announce the event of the year! I've got my call sign, at last.

I got it on my birthday, and it reads LA8PM. Since my name is Per Marienborg, I thought it pretty nice of Televerket (Norwegian FCC).

After having spent my two months summer holiday working, I bought a Sommerkamp FT250 transceiver for about $350. And a Mosley H-band vertical. In addition, I have a W3Dzz multi-dipole for 80 and 40.

Now, I am QRU on 10 meters almost every day. I may be identified by overmodulation, and the fact that I say Ah..., each third word and Well...about every seventh. I suffer from mike fright.

Per Marienborg LA8PM

Hoybraten Norway

Helping Hand

The STI Amateur Radio Club (WB9ADF) has undertaken a "Helping Hand" project to assist hams or would-be hams in solving their technical problems. We wish to extend this service to hams in all parts of the world, and particularly to those who are just getting started in ham radio or who are isolated from help. As a technical pool from which to draw solutions, the members are students working toward the Associate Degree in Electronic Engineering Technology, and are hams themselves for the most part, with a highly trained staff of instructors to back them up.

If you feel this project is of a worthy nature, we would appreciate it if you would mention it in a future issue. Inquiries and problems should be addressed to: STI Amateur Radio Club, Sams Technical Institute, Interstate Industrial Park, Fort Wayne, IN 46808.

Jeffrey Stineburg WA9TOJ
Trustee, STI Amateur Radio Club
WB9ADF

Why?

Why is it that...the only audible station on the entire 20 meter band has an operator who speaks only Esperanto and I have no way in God's world of making contact...the only 9M6 I ever heard was when the XYL gave me the supper ultimatum on the double...the one maritime mobile I really wanted came back to me when my swr bridge took a turn for the worse...the most important phone patch I ever tried was lost in band transition...the one opportunity to impress a VIP resulted in a "no propagation" day...the one last country I have looked for to make 200 was heard by the XYL while I was at work and I have been listening for 2 years while she has just learned how to tune the rig...the one piece of gear I ever bought through advertising was damaged before I got it...the QSLs were sent with an apology for being the wrong color...the YL with the most pleasing voice turned out to be an XYL...the day I was about to trade in my rig was the day I had the best contacts...my neighbor who complained about my interference admitted that his hi-fi broke down and then, when he had it repaired, he complained that he could *not* hear me: I have had no interruptions from my neighbors ever since I explained that my large antenna (beam) was for color TV...that the pink slips were an attempt to work WAFCC stations...I had failed to achieve this very simple goal.

Author Talkback

This letter is in reference to my article (published in the July '69 issue) "A Simple Effective RTTY Terminal Unit." In this article it was not made clear as to the counting of the pins of the integrated circuits involved. Since I have received so many letters and phone calls from readers who can't make the unit work, and the problem, with only one exception, has been the integrated circuits in the circuit wrong, I would like to point out the correct basing diagrams.

On the μA 710C, the tab is over pin 8 and looking at the bottom view, the pins are counted clockwise in ascending order. On the MC1429G, the pins are counted in the same manner, *except* that the tab is over pin 1.

As I mentioned, I have heard from quite a few readers who have had minor problems, now I would like to hear from a few who are using the circuit.

RG-8 Dummy Load

"Lossy Transmission Lines" by KH6IJ/1 (Feb 70) rang a bell with me: somewhere in the pile of junque I moved down here to the land of warm (?) winters, white likker, and some of the best looking women in the wide world is a hunk of RG-8/U labeled "Federal" which has a grey-ish looking dielectric rather than the usual translucent sort. About 60 feet long, this has long been my "Don't buy surplus line" convincer. Terminated w/50 ohms, fed by any 2 mtr xmttr thru a Bird Thruline will show, say 10 watts in, NO refl pwr. Move the Bird down to t'other end, feed in same 10 watts, *NOTHING OUT!!!* Repeat Experiment with two Birds, same results. Lossy? You bet! Loss showed up above about 20 MHz, negligible, lower. Experienced same thing with new 7/8" foam line, solid OD: 42 MHz loss 100% Found water in the foam!

New Church

Now that the impact of this incentive license business is being felt by the majority of radio amateurs, many of us are becoming dismayed by conditions on the portion of the bands we are forced to use. Even some of the old timers have given up amateur radio as a hobby.

I can't see any hope that The Organization will ever do anything for us. Yet they have so many advantages ever over any of the other three amateur publications: They alone have the amateur's bible and sunday school pamphlets; they are the umpires of all the games (contests); they set up the rules on how the games are played. There are no other referees.

As I see it, we need a new church, a new ritual, and above all a new bunch of deacons. Perhaps then we can get back that which was taken from us.

John McFarland
Port Richey FLA

Candid Suggestion

As editor/publisher, you will of course be responsible for everything in your mag, and quite probably a lot not in it. Perhaps you could perforate the page with your comments and the people not liking same can detach and file, while enjoying the rest?

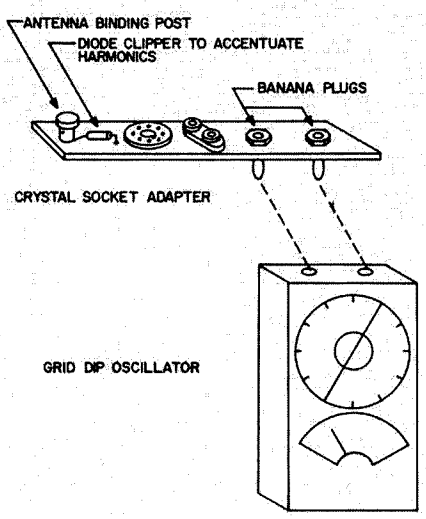
EXTRA

SERVICES FROM YOUR GRID DIP OSCILLATOR



A plug-in adapter turns the oscillator into an A1 crystal calibrator . . .

One of the handiest instruments around the average ham shack is the grid dip oscillator, but many hams do not get all of the advantages this little instrument can offer. Most people know that it is useful for finding the resonant frequency of an LC circuit, or for generating a signal someplace in the range, although it is not quite a substitute for a well calibrated signal generator in this respect.

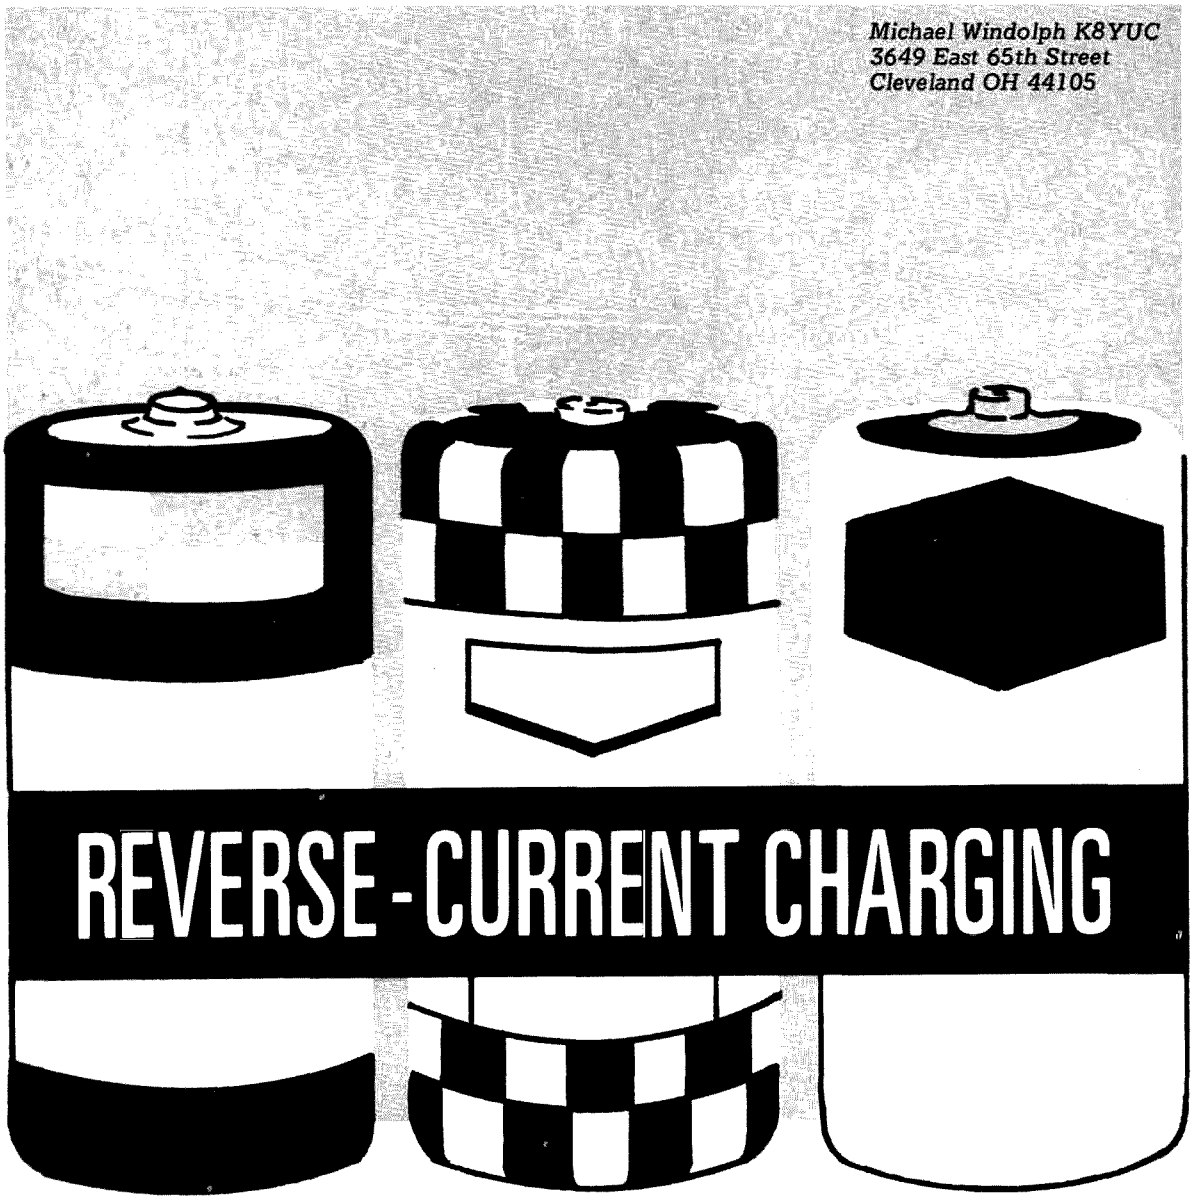
Many people do not realize that the grid dip oscillator makes an excellent crystal

calibrator as well. The typical grid dip oscillator uses a two-terminal coil and a two-section variable capacitor, connected in the form of a Colpitts oscillator circuit, with the variable capacitor providing the voltage division for proper feedback. This same circuit, with a quartz crystal replacing the coil, becomes a very satisfactory crystal oscillator. In this case, the variable capacitor becomes a trimming capacitor capable of putting the crystal on the proper frequency with considerable accuracy and also allowing a fairly wide latitude higher or lower for checking bandpass.

The meter reading gives an index of crystal activity. What is required is an adapter to match the pins of the crystal holders to the coil socket of the grid dip oscillator. I have made up such an adapter for my particular unit which consists of a 1½

Crystal socket adapter for grid dip oscillator extends the unit's capability by enabling it to read crystal activity.

inch by 4½ inch piece of masonite which carries two banana plugs to insert into the oscillator socket, and several different sizes of crystal holders, all connected in parallel, to accommodate any crystals I happen to have around the shack. I carry in my tool kit various assorted crystals. These give me spot frequencies for band edges and other reference points on all of the amateur bands.



In checking the higher frequency bands, I find it useful to add a diode clipper and have one permanently wired on the same adapter board. This is a 1N69 which simply goes from one side of the crystal to a terminal point at which I can attach an antenna or a lead to the input jack of the receiver. By simply attaching a short length of wire approximating a quarter wavelength at this frequency, I can provide a strong enough signal from the shack to enable me to check out my direction finding loop in the automobile fifty feet away.

In tuning up my 2 meter FM gear, I plug in a 3061.25 crystal (which is the transmitter oscillator crystal for my Link 2m FM unit) and then couple from the 1N69 to the input of the receiver. This provides a signal stronger than most of the local signals on the band, and adequate for initial tune-up. For finer adjustment of the i-f strip, I clip the lead from the 1N69 to the chassis close to the antenna input jack and the leakage provides a signal of the order of .2 μV, which is useful for final adjustment of the critical tuned circuits, the squelch control, and others. For best results, I leave the oscillator and the receiver on for a half hour or so to warm up, and then with the variable capacitor in the grid dip oscillator, I zero-beat the incoming signal of a station generally considered to be on frequency. Once this is done, I have a signal source on the bench with which to check the receiver for passband balance as indicated on the microammeter connected to the discriminator output.

One thing which could be added to increase the utility of the instrument is some form of modulation. It would not be too hard to add an outboard modulator connected to the oscillator through pin jacks or some other means. I have not done so simply because I happen to have a modulated signal generator in the shack.

REVERSE-CURRENT CHARGING

With an almost foolishly simple technique you can successfully recharge ordinary dry cells — and make them hold the charge — again and again!

Do your kids continually pester you with their battery-operated toys that don't work any more because the batteries are dead? Or do you use a flashlight or other battery-operated gadget often enough yourself that you wish you could afford rechargeable cells? Maybe this article can provide the necessary relief without any extra strain on your pocketbook.

Would you believe you could make a better battery charger? How about one that can charge at twice the usual rate or more, without damage to the battery? Or one that can charge, *really* charge the ordinary flashlight battery even higher than its bought-new charge?

It can be done! The process was invented in 1954 by Ernst Beer of the Netherlands

and bears patent number 2,752,550. Recently tested by Donald J. Vargo of Lewis Research Center in Cleveland, the process resulted in a better mousetrap – it really did the job better!

Although normal flashlight batteries will give, in a lifetime, about 2 or 3 A-hr of current (at 250 mA drain), with this new technique of recharging, some have given 30 to 40 A-hr and are still going strong!

Such claims sound fantastic –but try it before you decide it's impossible. It is quite a simple discovery and one that is not yet fully explained. But it works. Chemists are not really certain of all the chemical changes taking place in the normal battery. Theoretically, the chemical changes taking place when a cell is discharged should be reversed when the cell is charged. But this theory does not take into account an effect called "polarization," which tends to restrain the reaction. Besides, it has been found that with the ordinary dc charging technique the zinc of the regular LeClanche (flashlight) battery does not just migrate back to its proper place. It tends to clump up and form crystals or spikes of zinc on the negative electrode. Then further discharging thins out even more the zinc between clumps and you soon have holes in the zinc. Your cell dries out and you have a dead battery.

The discovery of Mr. Beer was a way to get the zinc to return to the negative electrode in an even layer instead of in clumps. This he accomplished by putting a small reverse current through the cell at the same time he was charging it. No one as yet has figured out just why this works but tests indicate that the reverse current seems to serve as a depolarizer. At any rate, it improves the efficiency of the charge many times.

In electroplating, this technique is used and results in much smoother, hard and even plating. Another effect of this higher efficiency in charging is that one can charge a cell at a much faster or higher rate without the cell heating up. With flashlight cells the only condition is that the cell not be already dead. Nickel–cadmium cells, of course, can be completely discharged and will still accept a charge.

It is best to recharge a carbon–zinc (flashlight) cell before it has dropped below 1.3V. After this point, the cell soon develops holes in the zinc with consequent drying out and deterioration. However, it was found that even a cell with some very small holes could be rejuvenated because the zinc is recoated so as to actually seal up the small holes! A lead–acid cell which would accept no more that a 50% charge by the ordinary technique was built up to a complete charge by alternately charging and discharging with this new circuit until it was up to full capacity.

The circuit is simplicity itself. All that is necessary beyond the diode rectifier and the resistor (or capacitor used as a reactance-type resistor) found in the cheapest recharger, is another resistor across the rectifier. This second resistor allows some ac to flow through the cell and so the technique is called asymmetrical alternating-current charging. It has been found to work best when about 10% of the forward current is allowed to flow backward in the circuit. You can easily calculate the necessary resistance.

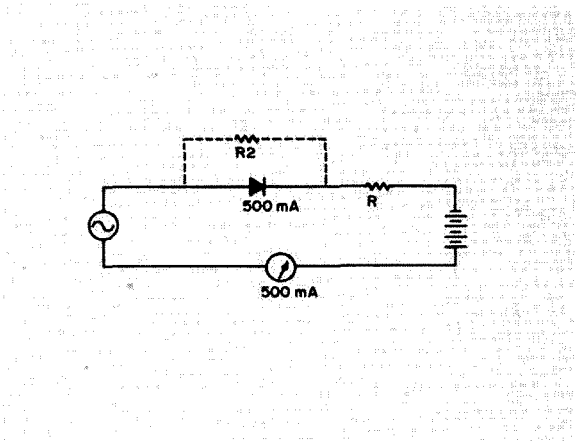

Fig. 1.

First set up your circuit as in Fig. 1. By trial and error figure out the resistance of R. Do this by deciding how much charging current you want; e.g., for a typical nickel–cadmium cell, you might choose the 100 mA they are usually rated for – or about the same or more for an ordinary flashlight cell. Begin by using a high resistance at R. This depends

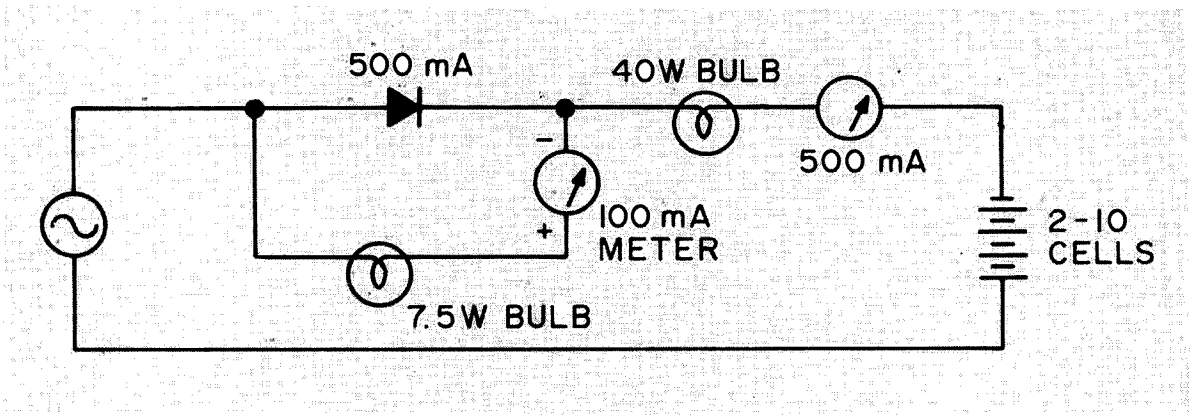

Fig. 2

on your ac source; if you use 117V you could try a 10W light bulb in series, but with only 25V or so from a transformer you could get by with a few thousand ohms to begin with. Then gradually reduce the resistance (or use a higher wattage light bulb) till the meter shows about 100 mA. Remember, the resistance has to be able to carry 100 mA, so use one of adequate rating.

Next, multiply R by 10 and place the corresponding resistor across the rectifier and you're finished. Make it big enough to carry the 10 mA of current it will be drawing in reverse. Or if you like to use trial and error, you can try different resistors at R2 also, starting with one at least 10 times greater than R and reducing it till you get the 10 mA reverse current. Remember, this is *reverse* current, so connect your meter leads accordingly.

As previously stated, this system allows recharging at a much higher rate than ordinary chargers, and without overheating a cell, I recharge my 100 mA nickel–cadmium cells at 275 mA with about 30 mA reverse current flowing. Figure 2 shows the circuit of my complete battery charger using this new technique, along with an added refinement. Due to the 117V source current and the current-dropping light bulbs, this circuit enables one to charge anywhere from 2 to 8 or more cells in series at one time without changing the circuit at all for each cell I add to the circuit This is because the line voltage with only the bulbs in series produces an essentially constant-current source for the rectifier and any number of cells. Actually, by bulb ratings one should use a 4W bulb to go with the 40W bulb, but according to actual current drawn, the 7.5W bulb proved a better match to draw 10% of the forward current.

The meters are not necessary, of course. Once you measure and obtain the current you want, or just use this circuit as is, the meters are no longer needed unless you want to be sure current is being drawn. With this circuit you will draw about 275 mA through from 2 to 8 nickel–cadmium cells. If you use ordinary flashlight cells there will be less current as carbon–zinc cells have more internal resistance than nickel–cadmium cells.

The best way to determine length of charge is to figure the normal capacity of the cell and charge accordingly; a 1 A-hr cell, for example, could be charged at 250 mA for about four or five hours. Cells have been left for days in this charging setup without any apparent damage, so don't be too concerned over a few extra hours.

Another way to check charge is to measure the voltage across the cells. Towards the end of a full charge the voltage will rise. Ordinary flashlight cells, if new, can be charged to almost 2V each. They lose the extra voltage soon afterwards but it is an increase of energy that no common charger will give.

So, dig out all your dying batteries and see which ones are capable of a lot more life.

A Poor Man's Frequency Meter

How to turn a few cheap surplus sows' ears into a satin handbag.

While the FM'ers may be the only hams around who make a religion out of being precisely on frequency, virtually *all* active amateurs have a need for a frequency meter periodically. Well, this may come as something of a shock to some, but there *is* a way to measure frequency accurately without the use of expensive equipment. With a handful of parts and a few items found commonly around the radio shop, you can build the *poor man's frequency meter*, which is capable of tolerances that should amaze you.

This is *not* a substitute for a good frequency meter for commercial use, but if you have a limited number of frequencies that you want to be "dead on," this may be the answer. And it ought to be a must for the group of fellows who maintain the local FM repeater.

A nice feature of the *poor man's frequency meter* is the fact that it puts to use that old surplus military communications receiver which has undoubtedly been sitting around in a dark corner of your basement under piles of old magazines and discarded dynamotors. It also uses any old commonly available surplus wideband FM receiver, such as the types advertised in this issue of 73.

The idea is not new; hams in the two-way business will recognize it as the system that has been used for many years for the Motorola station monitor and various other common applications. Basically, it is composed of four major units:

- Receiver converter with calibration oscillator constructed on a high-band front-end deck from an old Motorola Sensicon A receiver chassis.
- Monitor receiver (any 150 MHz wideband receiver); a low i-f of 455 kHz is best.
- WWV receiver (here is where the surplus communications receiver comes in).
- Accessory items (hang a modulation meter on it).

The block diagram of Fig. 1 shows how the individual items of equipment are interconnected to form the frequency meter. Note that although a narrowband receiver can be used, a more dependable "off frequency" indication is obtainable with a wideband i-f receiver. Periodic calibration (before use) to WWV is recommended for high accuracy measurements; however, the unit will maintain its operating frequency to within 1 kHz (an error of 0.0006%) for an ambient temperature within the range of −20°C to +60°C.

Principle of Operation

The frequency converter operates on the heterodyne principle. A station frequency is

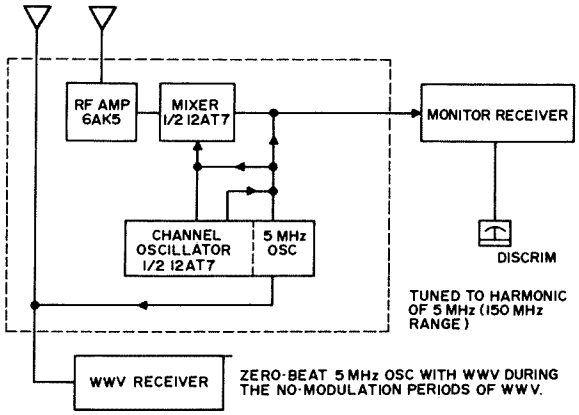

Fig. 1. This system block diagram shows how equipment should be interconnected to make the frequency meter setup.

monitored by heterodyning its carrier with the output frequency of the crystal oscillator and then feeding the resultant frequency of these two signals into the calibrated monitor receiver. If the beat frequency between the crystal oscillator signal and the monitored carrier is exactly equal to the frequency to which the receiver is aligned, the discriminator meter will indicate zero. If the beat frequency is lower or higher in frequency than the one to which the receiver is aligned, a direct indication of carrier frequency error in the monitored transmitter will be given on the meter.

The monitor receiver is aligned to a predetermined frequency. The specific frequency used will depend upon the spurious harmonics emitted by the channel crystals which will be required to monitor the specific carrier channels in consideration, plus the operating frequency to be measured.

The beat frequency fed to the control receiver may be either the sum or difference frequency of the channel crystal frequency and the monitored carrier frequency. Channel crystals for operation in the range from approximately 1.6 to 12.5 MHz may be used.

Calibration Oscillator

The calibrating oscillator consists basically of an rf amplifier stage, a mixer, and an oscillator. The calibrating crystal, shunted by a trimmer capacitor for any minor adjustment of oscillator frequency, is used for calibrating the monitor receiver.

Although the crystal is temperature controlled, a *greater degree of accuracy is obtainable without the use of the heater.* The trimmer capacitor provides *exact* calibration of the crystal frequency at any temperature by zero-beating the oscillator against the WWV signal.

The crystal heater should be used *only* when a quick check is necessary; such as, where it is desired to quickly bring the crystal to a temperature that would eventually be reached due to the heat dissipation of the equipment.

The control receiver may operate in the 145-160 MHz range; therefore, when using a 5 MHz calibration crystal, the 29th, 30th, 31st, or 32nd harmonic of the 5 MHz crystal

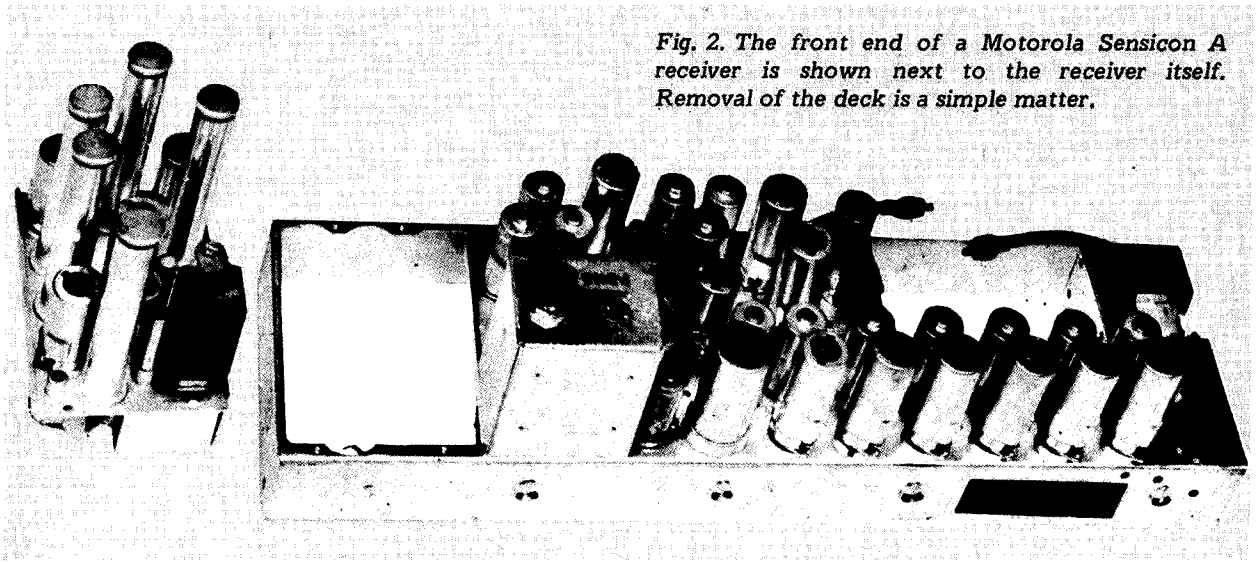

Fig. 2. The front end of a Motorola Sensicon A receiver is shown next to the receiver itself. Removal of the deck is a simple matter.

frequency is used to calibrate the receiver to 145, 150, 155, or 160 MHz.

The selector switch operates in conjunction with the calibrating oscillator. This switch may be used to select any one of several crystals as the frequency controlling element of the oscillator. These crystals include the 5 MHz calibration crystal and the five channel crystals.

One half of a 12AT7 tube is used as the oscillator while the other half of the tube functions as the mixer. The carrier frequency to be monitored is picked up by the VHF antenna, amplified by the 6AK5 amplifier, and then mixed with the selected channel crystal frequency. The output of the mixer is fed to the calibrated monitor receiver where it is determined if the transmitted carrier is on frequency.

Assume that it is desired to monitor the output of the transmitter which is operating on 146.94 MHz and that the control receiver has been calibrated at 150 MHz. The necessary channel crystal frequency will be the difference between 146.94 MHz and 150 MHz, or 3.06 MHz. If the transmitter is on frequency, the 146.94 MHz signal will mix with the 3.06 MHz channel crystal frequency to produce an input signal of 150 MHz at the control receiver. In this case, no indication will be given by the discriminator meter. If the monitored transmitter carrier is above or below its designated frequency, the input signal to the monitor receiver will be above or below 150 MHz, causing the discriminator to produce an output voltage. This voltage is fed to the meter, which is calibrated in kilohertz to give a direct reading of carrier frequency error.

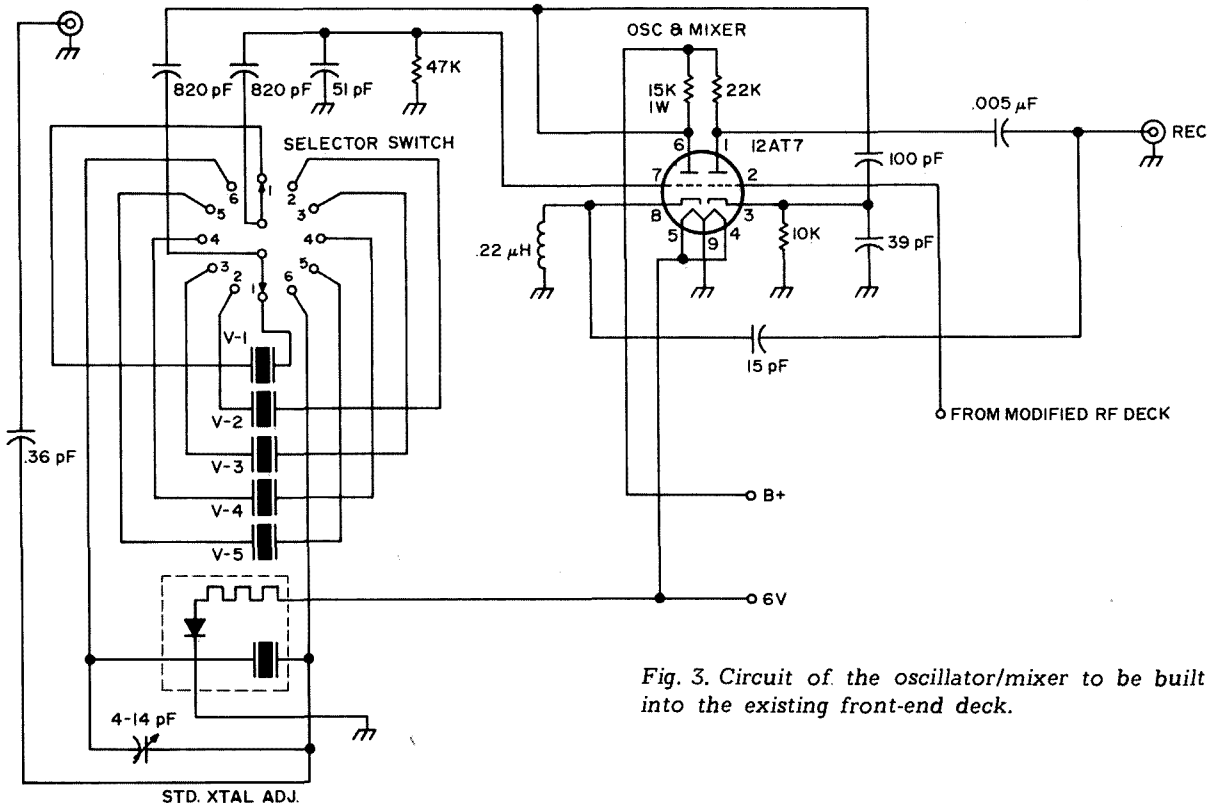

Fig. 3. Circuit of the oscillator/mixer to be built into the existing front-end deck.

When monitoring transmitters which operate in the 420–450 MHz band, the monitor must be placed so that the monitor antenna is within a few feet of the transmitter. For this application, the frequency of the stage preceding the final tripler is monitored. This is done by selecting a difference frequency crystal for the monitor which, when beat against the frequency of the transmitter stage preceding the tripler, produces the frequency at which the control receiver is tuned.

Say that it is desired to monitor the output of a transmitter operating on 443.75 and that the monitor receiver is calibrated at 150 MHz. The channel crystal frequency is determined as follows:

443.70 ÷ 3 (tripler) = 147.90
(frequency actually monitored)
150 – 147.90 = 2.1 MHz
(channel frequency crystal)

If the transmitter is on frequency, the frequency of the stage preceding the final tripler will mix with the 2.1 MHz channel crystal frequency to produce an input signal of 150 MHz at the monitor receiver. In this case, no indication will be given by the discriminator meter. If the monitored transmitter carrier is above or below its designated frequency, the input signal to the monitor receiver will be above or below 150 MHz, causing the discriminator to produce a positive or negative output voltage. This voltage is fed to the discriminator meter *which can be calibrated to give a direct reading of carrier frequency error.*

Any error in carrier frequency indicated on the discriminator meter is an error in the frequency of the stage preceding the tripler; therefore, the error in the transmitter signal from the final amplifier will be three times as great. When using this method of monitoring, check the output (420–450) of the transmitter with a reliable wavemeter to ascertain that proper frequency multiplication is made.

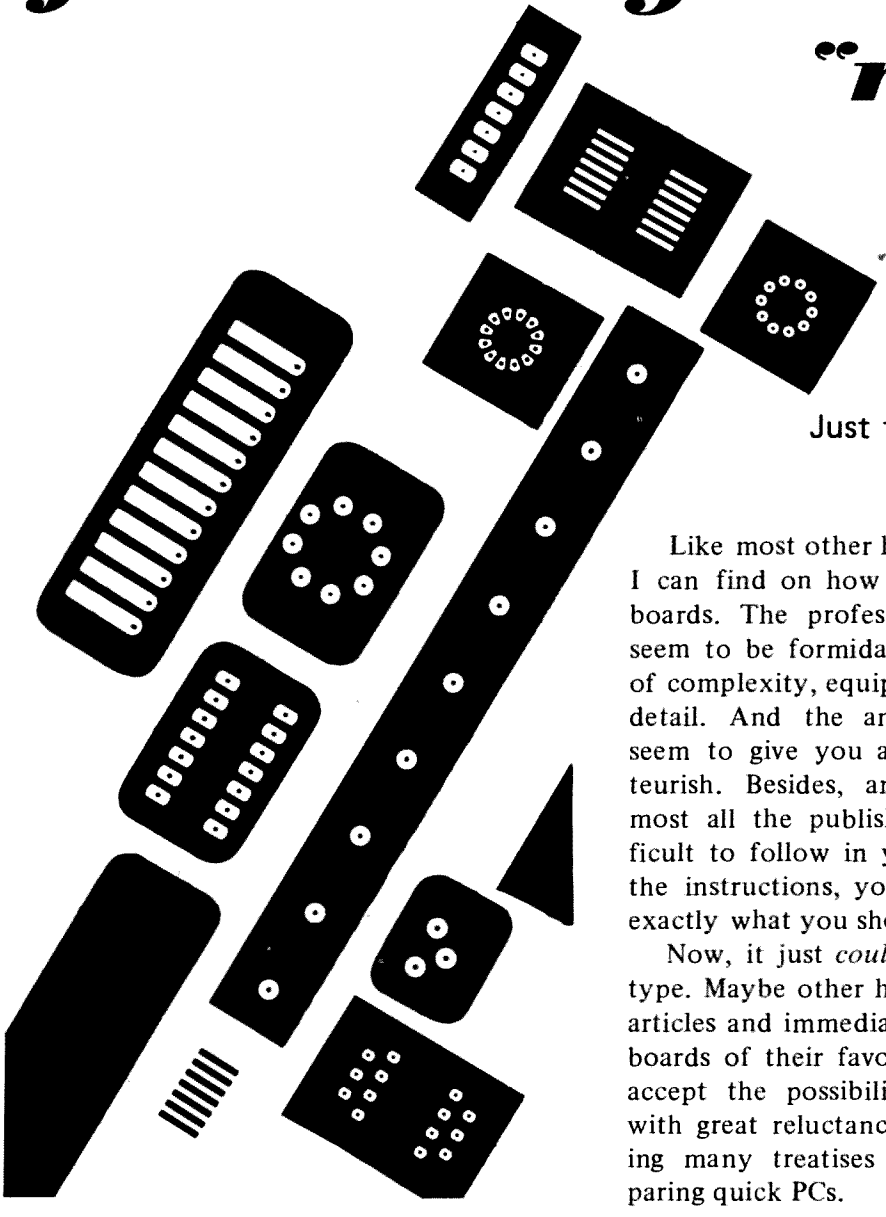
Channel Crystal Accuracy

Since the fundamental frequency of the channel crystals is used, any error in crystal frequency is not multiplied. Therefore, the error in monitoring a frequency by this method is very small. Crystals are held to within 0.002% of the specified frequency over the ambient temperature range of –30°C to +60°C. Therefore, with the previous 2 meter example, the maximum frequency error of the 3.06 MHz crystal would be 3.06 x 0.0020%. At the frequency being monitored, the percentage error would not be discernible on the meter.

The "improvement factor" of possible percentage accuracy at the channel crystal frequency over the percentage accuracy at the carrier frequency is approximately the same ratio as the monitored carrier frequency over the channel crystal frequency, or 146.94/3.06 equals 48. This is another way of stating that the channel crystal is more than 48 times as good percentage-wise at the monitored frequency than at its fundamental frequency.

The improvement factor may be checked on any channel by the above method. It will always remain reasonably high; therefore, the possible error of the channel crystal frequency is negligible.

The front end deck of a Motorola Sensicon A receiver provides an ideal converter for the *poor man's frequency meter.* Figure 2 shows this assembly as a separate unit as well as in its original form installed in a Motorola Sensicon A receiver. The part numbers referred to in the modification procedures described here are those part numbers called out in the Motorola manual for the Sensicon A 150 MHz receiver. The procedure is quite simple, too. Here is all you do:



1. Replace R102 (2.2MΩ) with 3.3 MΩ and ground low side.
2. Remove C104.
3. Replace R103 (33 kΩ) with (470 kΩ).
4. Replace L101 with a 100 kΩ resistor.
5. Remove R112 (3.9 kΩ), complete B+ circuit.
6. Replace X102 with 9-pin socket (with shield).
7. Remove wire from pin 1 and connect to pin 2.
8. Connect 1 MΩ resistor from pin 2 to ground.
9. Wire 12AT7 socket for 6V filaments. (Connect 6V to pins 4 and 5, and ground pin 9.)

This completes the modification of the rf amplifier. To construct the oscillator/mixer, remove the balance of the circuitry on the deck with the exception of the crystal socket. Then build the circuit as shown in Fig. 3 around the new X102. Be sure to use silver mica capacitors in the crystal circuits. The crystals themselves are Motorola SFMT-2 (R11, 5 MHz), and they may be obtained from Sentry or International.

The Sensicon A receiver is found in a number of the older, less expensive Motorola FM units, such as the 40V, the early 41V, and all Model series bearing the AAV and AAD suffix. These are available from Newsome (Detroit), Mann (Tarzana, Calif.), C & H (Long Beach, Calif.), and Gregory (Saddlebrook, N.J.). . . . W6YAN■

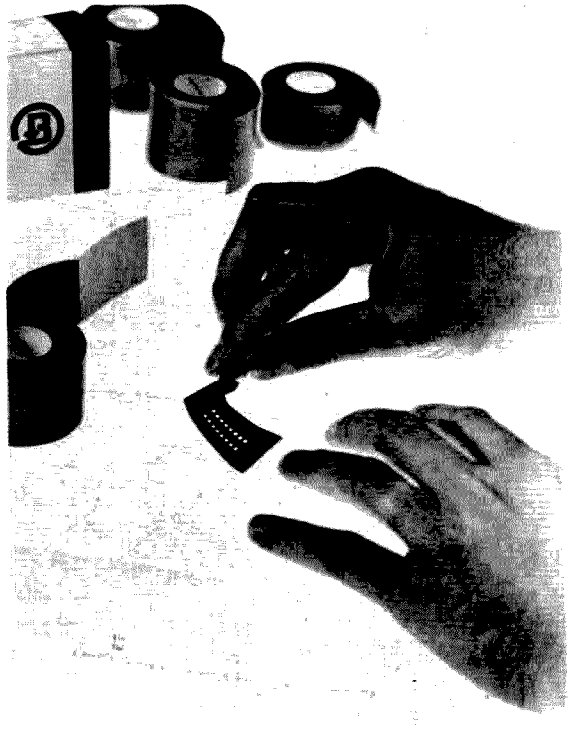
Professional PCs from roll-your-own "negs"



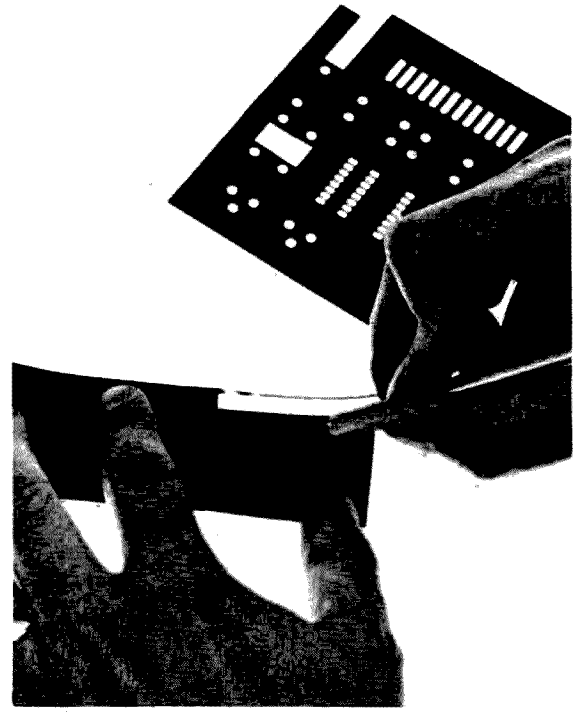
Just the thing for the next club project!

Like most other hams, I read every article I can find on how to make printed-circuit boards. The professional processes always seem to be formidable from the standpoint of complexity, equipment requirements, and detail. And the amateur methods always seem to give you a board that *looks* amateurish. Besides, amateur or professional, most all the published procedures are difficult to follow in your mind; as you read the instructions, you find it hard to know exactly what you should be doing and when.

Now, it just *could* be that I'm the dense type. Maybe other hams breeze through the articles and immediately whip up five or six boards of their favorite circuits. I began to accept the possibility of my "numbness" with great reluctance and only after digesting many treatises on the subject of preparing quick PCs.

Then one day, while I was preparing a batch of "new product" announcements for a trade magazine in Chicago, I happened across a news release from Sol Shein Advertising Agency that extolled the virtues of a simplified PC production process developed by Bishop Graphics, Inc., a California firm. The text supplied rapidly lost me as had all the previous articles I'd read, but the cagy

Step 1. Negative (B-Neg) version of a typical dual in-line IC package is laid down just the way positive configurations are handled.



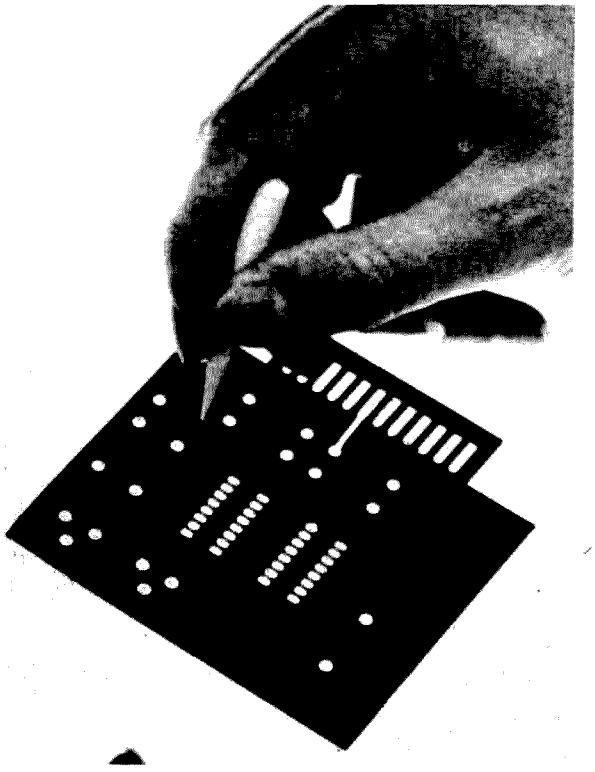
people at Shein were clever enough to foresee possible confusion, so they included a raft of photos that showed the complete preparation process, from layout to finished board.

I made a mental note at the time to write an article for 73 Magazine at my earliest opportunity; 73 readers, I reasoned, would appreciate as much as I do a truly easy way to make their own professional PC boards. The "mental notes" proved to be ill-filed, however, because I lost them as well as all of the photos when I moved from the Chicago area to Peterborough. But – as luck would have it – the Shein agency was on the ball; their press releases were also sent to 73, photos and all.

The Bishop Process

The Bishop Graphics company produces a photoresist solution that can be used to sensitize a copper-clad board for photo exposure. The product line also includes developer, etchant, and stripper; but the big thing is the technique they have for eliminating any drafting, camera work, or the necessity for darkroom processing.

The Bishop method involves the use of preprinted "negatives" which can be placed in any configuration to suit the needs of the individual. The negative patterns – including transistor layouts, dual in-line IC patterns, and a thousand and one other variations – come already printed on pressure-sensitive "B-Neg" acetate. The company also



Step 2. Opaque black B-Neg "background" film fills in spaces between terminals.

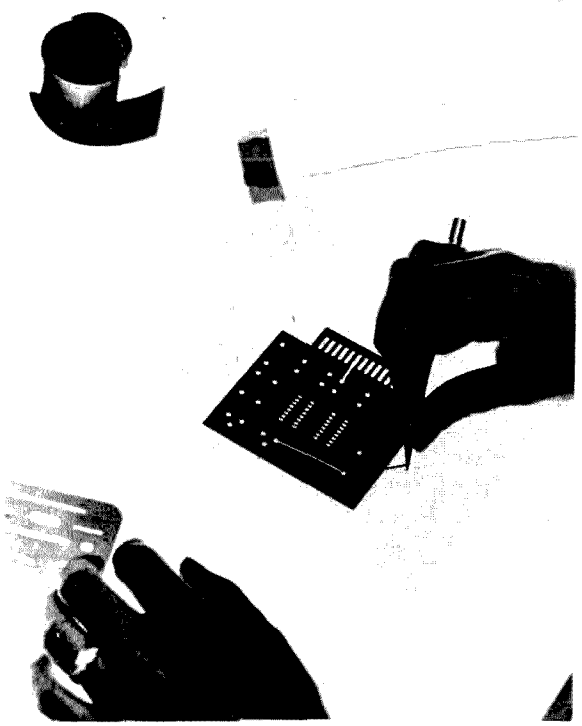
supplies pure black pressure-sensitive B-Neg material so that anyone can form his own completely custom-designed negatives.

The completed B-Neg pattern can be used to produce a positive pattern on the presensitized (photoresist) copper-clad laminate or film. And the laminate, quickly etched on the spot, becomes a circuit board ready for drilling and component wiring. The whole

process takes an hour or two –and the result is a *professional* job.

The steps are simple. After the B-Neg pattern is laid down on a thin transparent Mylar, acetate, or film base, the clear areas are overlaid with a mask of B-Neg opaque film. Then, with a sharpened piece of white chalk or any light marker, interconnecting circuit lines are drawn on the B-Neg mask to establish conductor paths. Corrections of

Step 3. Circuit lines are traced in white chalk or marking pencil.



mistakes or changes are easy. Simply rub away the chalk and redraw the conductors.

The final conductor paths are established by cutting along the established chalk lines and peeling away the B-Neg material. Fine conductors may be scribed. Conductor paths can just as easily be eliminated by covering with the black B-Neg mask material.

The completed B-Neg and copper-clad laminate (which has been coated with Bishop photoresist) are placed in a contact frame or in a plate glass "sandwich." Exposure under an ultraviolet light source (or a noontime summer sun) takes no more than a few minutes, and the subsequent developing, etching and strip/rinse cycles can be completed in approximately an hour. The board is then ready for drilling and assembly.

If you are accustomed to producing your negatives with a regular process camera, you should know that existing negatives can also be changed quickly with B-Neg. Entire patterns can be relocated or conductor traces changed without retaping and reshooting original artwork.

All B-Neg pads and patterns are available in 1:1 scale. Other necessary materials are available from Bishop dealers: Mylar matte base material and grids, knife, tweezers, erasing shields (for cutting accurate conductor paths), and white charcoal pencils. If you don't know where to get Bishop's B-Neg stuff, write to the main office at 7300

Step 4. Using common eraser shield for a guide, neat circuit paths are cut and peeled.

Radford Ave., No. Hollywood, Calif. 91605. Chances are you'll even get a free sample.

Getting the Material Together

There are several ways you can go when you get on a PC production kick. You can do it the easy way by sending $28.50 to Bishop Graphics, which gets you a complete PC production kit, including an exposure frame and a couple of processing trays. Or you can scrounge and cumshaw and do

everything kind of slipshod the way I do. My system differs a bit from Bishop's recommended procedure, because I am inherently cheap; as a consequence, I don't employ the trays and contact frames and other trinkets and niceties the Bishop brochures rave about. But my method is just about as effective, even if a bit more cumbersome . . . and after all, it *is* my story.

The table presented here shows the material recommended by Bishop alongside the material I recommend for the cheapskate scroungers. With care, you should get excellent results regardless of which bill of materials you use.

Step 5. Finished B-Neg and photoresist-coated copper-clad laminate are placed in contact frame.

Bill of Materials

Bishop Catalog number, description, and price.			Scroungers list and price
	B-Neg material and patterns as necessary		Same as at left
7902	Photoresist, 7 oz. aerosol spray	$6.85	6.85 Same as at left
7904	Developer	1.50	1.50 Same as at left
7905	Stripper	1.25	1.25 Same as at left
7906	Tray set	1.25	2 shallow pans—one metal, one ceramic, plastic, or paper.
7908	Etchant	5.80	5.80 Same as at left
7909	Contact pressure frame	7.55	2.98 8 x 10" picture frame w/glass and backing
7952	4 x 6" boards (1 side copper)	4.50	4.50 Same as at left
	Ultraviolet fluorescent lamp	29.95	Free Sunlight
		$56.65	21.88

Preparing the Board

Prepare the copper-clad laminate *carefully*. All soil, stains, and foreign matter must be completely removed. Scrub it with ordinary household cleanser and a stiff brush. Rinse. Repeat the scrubbing. Rinse again. Wipe off thoroughly with a clean towel. Rinse *again*. Now air-dry (or oven-dry at 110° to 120°F), always handling with care and never touching the surface with bare hands or fingers. (Residual oils in the skin will reduce the quality of the end result.)

If you don't have a darkroom, wait until after dark before you prepare the board. In the dimmest light possible, place the clean, copper-clad laminate on a protective background (several paper towels) and spray on a full, even coat of Bishop photoresist, following the directions on the can. Immediately pick up the board and slant one edge toward the floor. As the 'resist runs to the lower edge and forms a bead, soak the bead off with a paper towel. Turn the board 90° and repeat (the equivalent of a slow spinning action) so that excess 'resist is removed and no longer forms droplets at the lower edge. Then place the board flat for air-drying (or in an oven at 110° to 120°F). The 'resist will flow out, leaving a very even layer. For further processing, the board must be completely dry . . . no tackiness, no solvent smell.

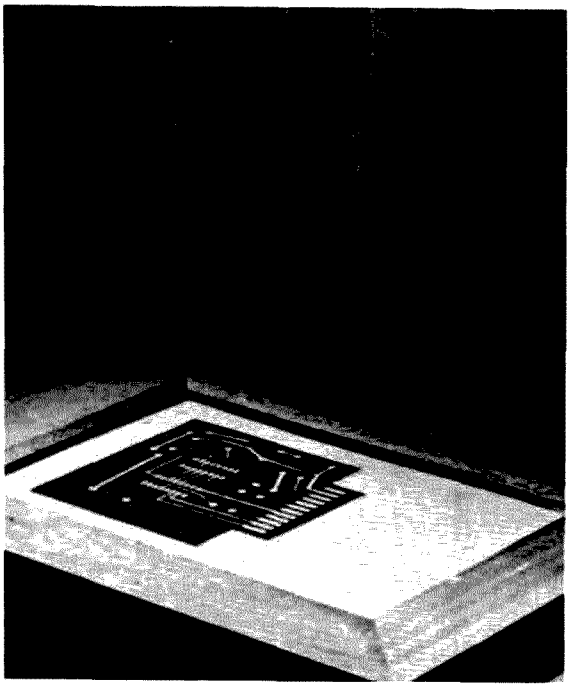
With the B-Neg protomaster and a contact frame close at hand, half-fill a shallow metal or ceramic dish or tray. (Don't use plastic or you'll find yourself with no dish and a big mess.)

VHF FM MONITOR RECEIVER

NEW

100% MADE IN U.S.A.

Only $79.95 Postpaid in the U.S.A.



The new **VANGUARD FMR-150** is not just another frequency converter but a complete FM receiver with outstanding performance.

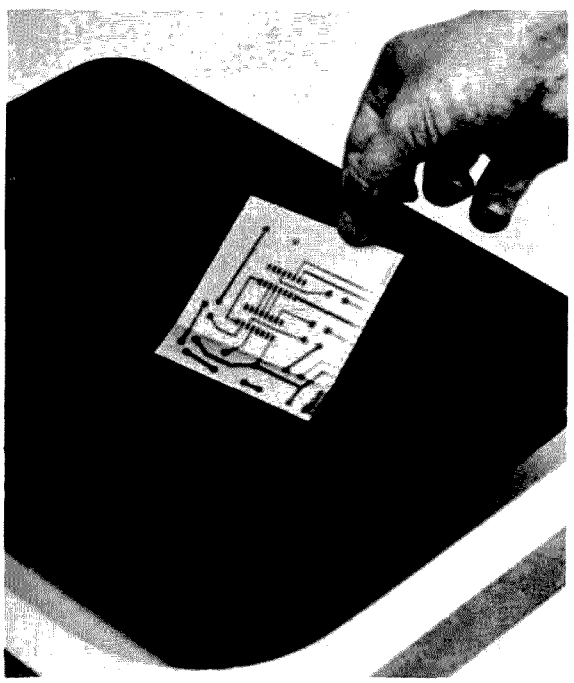
Check the following features and see why it's the best. Collins IF filter for separating those closely spaced stations you hear together on other sets● Double conversion to eliminate interference from image frequencies● Dual Gate MOSFET RF stage for low noise. .2 uv. sensitivity, and minimum cross modulation● Automatic squelch for eliminating noise● Self-contained speaker● Operates on 12v. D.C. negative ground● Heavy gauge anodized aluminum case 6" x 7" x 1-3/8"● Provision for 4 crystal controlled channels at the push of a button● One channel of your choice supplied with receiver. Additional channels available just by plugging in another crystal at $4.95 ea. No need to buy another RF unit as in some other sets● Factory tuned to cover any 6MHz segment from 135 to 175 MHz.

HOW TO ORDER: The **VANGUARD FMR-150** is available only direct from our factory. Include remittance in full plus sales tax if you reside in N. Y. Be sure to state the 6MHz segment you will want to cover and the exact push button frequencies to be included.

VANGUARD LABS Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

Open the contact frame (or substitute therefor), placing the B-Neg face down on the glass. Make sure the sprayed board is completely dry and place the 'resist side against the B-Neg. Close and lock the frame, and place it under the blacklight source about 3 in. from the lamps. Expose for two to four minutes (a test or two will give you a

Step 6. Exposure to ordinary black-light fluorescent lamps takes less than four minutes.



Step 7. It takes only a few seconds for a crisp pattern to show in the developer tray.

reliable guide). If you use bright sunlight, allow 10–15 minutes around noon.

Immediately after exposure, immerse the board in the developer. Agitate gently; 30 sec to 1 minute should produce a bright, sharp image. Now rinse in running water at the sink, where etching and stripping will soon complete the process.

To etch the board, dissolve one packet of Bishop etchant powder in a pint of hot water in a *plastic* tray. Immerse the exposed

Step 8. The developed board is immersed in a solution of Bishop etchant and left for an hour.

and developed board. In about an hour, the board will be fully etched. Gentle agitation from time to time will speed the process. Hot water around the plastic tray will keep the etching solution warmer, speeding the process.

As soon as the etching process is complete, pour some Bishop stripper over the board, and, with water running over it, rub the stripper over the pattern until the copper is glossy . . . and all the dye is removed. Then dry the board and it is ready for drilling and assembly.

When you add the prices shown in the table, you may feel that the overall cost of producing your own boards is prohibitive. And of course it *would* be for a single board. But the amounts of chemicals you get are sufficient to turn out quite a few printed

SIGNAL/ONE'S CX7 GIVES YOU

ELECTRONIC COUNTER FREQUENCY READOUT

Electronic counters belong in the laboratory . . . because they're big, expensive, precision instruments . . . right? So what's one doing in the CX7? Well, it gives you . . . . . .

- **CALIBRATION ACCURACY OF 100 HZ** at every point in every band
- **READOUT DIRECT TO 100 HZ** . . . without interpolation
- **LIFETIME PRECISION** . . . free of error due to aging or environment
- **BIG, BRIGHT DISPLAY** . . . virtually impossible to mis-read

SIGNAL/ONE engineers did it by putting state-of-the-art technology to work in a precision counter no larger than a small book. This remarkable unit actually counts each individual cycle of VFO output during a precise (crystal-controlled) 1/100 second time interval . . . and displays the last four digits of the total on an electronic readout. (For example, a VFO frequency of 3521.7 kHz (3,521,700 cycles/second) yields a 1/100 second count of 35,217 . . . and the display shows **521.7 kHz**). The readout is as accurate as the 1/100 second timing. Timing is derived digitally from the 100 kHz reference standard. So, by simply zero-beating the 100 kHz oscilator to WWV (or a BC station) you automatically calibrate the VFO to 100 Hz accuracy . . everywhere.

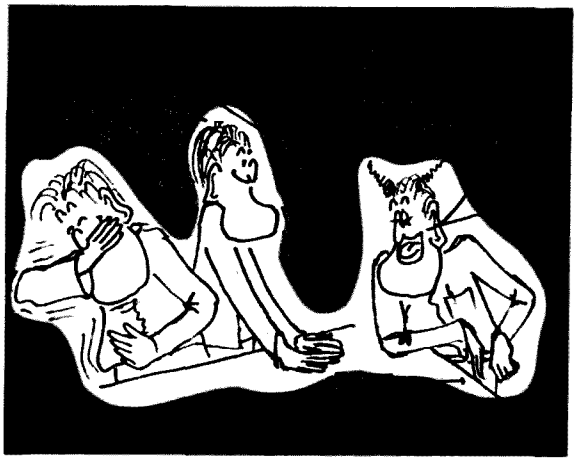
how I read the Radio Operators Handbook and found happiness

. . . and he thought a logarithm was the beat of a jungle drum

R. W. Johnson
31 Maclarnon Road
Salem NH



There are one hundred fifty-four million ham operators living on my street. Some of them sleep six to a room. Together with the thirty-two thousand at the office that I work with and socialize with every day, you can probably well imagine that for some length of time, I have felt somewhat alone if not downright black-sheepish. considering the fact that up until last Saturday evening, I didn't know the difference between a waveform and a potentiometer. For years,

whether at parties or the water cooler, I felt left out.

Don't get me wrong! I'm not insinuating that the ham population has grown to unhealthy proportions or anything. All I'm saying is that when the time comes that a milkman or grocer or any other normal type of unassuming personage such as myself develops serious psychological traumas because of an inability to discuss capacitive reactance with every Tom, Dick, and Alfred, then one must do something. What one must do is largely up to oneself. I – having a very agile and analytical mind – chose to acquire an education in electronics.

So last Saturday I read the amateur radio operator's handbook –from cover to cover (minus the ads). Granted, this doesn't make me an engineer. But you wouldn't believe how it has changed my life. Things are different now. I not only feel confidence in my relationships with my contemporaries, but –and get this– I actually feel *a little cocky*. Don't laugh! I know what you're thinking. *Here's a guy who reads something and comes on like the guy who wrote the book.* Right? Isn't that what you're thinking? For my defense, I submit that all things are relative (I didn't make that up; I read it somewhere). What I mean is simply this: My knowledge on Saturday night compared to my knowledge on Friday night makes me something of a Marconi–Faraday–David Niven conglomerate. It's unbelievable how my life has changed. My confidence is not unlike that of a Karate black-belt.

Like yesterday, for instance, I went into the local Radio Shack. I didn't need a thing. It was just a place where I could feel at home –*wanted*, if you will. I asked the electronics guy if he had any microfarads, and you could tell he was really impressed because he didn't say anything for a while. He just sort of looked around and blinked a couple of times. He asked me if I was putting him on. I assured him I wasn't and he muttered something that I couldn't quite catch, and called a couple of other guys over to meet me. Their names were Chuck and Lennie, if my memory serves me right. Anyway, the four of us stood around smoking for a while and talking about this and that. Chuck and Lennie were a couple of pretty good guys. Lennie kept giving me cigarettes and lighting them for me. You could tell he wanted to keep me around for a while. Then, the first guy I had spoken to asked me how many microfarads I wanted. I told him I could use about a handful (I knew

they had to be cheaper in quantity orders). "Wouldn't use anything else," I said with a sly, knowing smile. You could tell they got a big kick out of this because Lennie kept nudging Chuck.

Now don't get me wrong. I'm not bragging or anything. That's not the point of me telling you all this. This is just to illustrate what a little erudition can do.

When I left, Lennie, Chuck, and the other guy were all hee-hawing their heads off and slapping each other's shoulders and everything. Chuck looked like he was ready to roll on the floor. Boy! You could tell that they really enjoyed electronics.

Like I say, though, life is different for me now. I can *talk* to people. I really can! New worlds have opened up to me. I feel comfortable – contented – relaxed– IN!

A few days ago, I put a dipole on my roof. It's beautiful. The ole sun reflects off that thing like there was no tomorrow. And the gleam is enough to knock your eye out (what kind of wax do you use on those things anyway?)

Hank, my next door neighbor, says I ought to get a "rig" for it. But I figure it can wait a while. First things first, you know. I'm in no hurry. I figure: today a dipole– tomorrow an ohm.

. . . WOW ■

The first eight years of amateur FM repeater operation in the United States has been a period of growth and stabilization. Today, because of the unprecedented popularity of repeaters and channelized operation on the VHF amateur bands, we are faced with such problems as:

- *Frequencies for new systems*
- *Channelizing*
- *Logical frequency pairing*
- *Deviation and bandwidth*
- *Tone frequency standards*
- *Guard channels*
- *Command methods*
- *Selective calling standards*

Many systems have grown in their present shapes because of availability of equipment, bulk availability of crystals, long-term usage on certain channels, patterning from a successful scheme, or because it seemed the thing to do at the time. In most cases, changes were made before cost prevented modification and systems developed so that members were served as necessary. But now it is 1970, we are thinking nationally—and for good reason. Travelers report that directories are inaccurate and that they have found activity not quite as reported or that the local repeaters are tone-protected. Frequencies in one area are not used in another. Interconnection presents problems in selective calling and command. Multichannel users compromise equipment performance. One area is narrowband, the other wide. So-called national frequencies are used with a variety of input frequencies, depending on area. UHF users find a wild variety of pairings and come to the conclusion that this band is haphazardly planned with frequencies confidential.

But all is not so bleak. With a little forethought, users can plan together, applying techniques known as spectrum engineering, frequency administration and conservation, or whatever name suits. It has been done with great success for the past two years in the west and I'll wager that with a little intentional planning that even in Los Angeles — that great super hodge-podge of "secret channels" and RF overlay — a measure of order will result in the next five years. Let's take a look, then, at what we can achieve and how to go about it with minimum outlay.

First there must be some form of mutual planning, whether on an agreed basis, by meetings of the repeater groups in a state or area, or by the principal repeater group taking the initiative. Acceptable standards can be determined and, though planned changeovers would meet with little acceptance, any changes could conform to agreements. Most amateur relay systems have changed enough in five years to prove they are fluid. In some concentrated areas of relay activity, coordinators, gentlemen's agreements, or adherence to accepted plans have been very successful. To my knowledge, very few systems have gone into service haphazardly and without thought. Those that ran into technical or operational problems soon changed because of opposition or impracticality.

NEW RELAYS

Where is there room for additional groups, especially in areas of intense usage? By being careful with the spectrum — that is, by channelizing and establishing standards of bandwidth — the greatest number of channels can be rendered with full compatibility. A generally accepted plan for 2-meter FM operation, for example, is each 60 kHz up from 146.04, leaving the lower portion to AM and DX'ers. Greatest activity still seems to be the upper portion of 146 MHz. A significant amount of narrowband FM equipment is available and the 30 kHz channel standard on 2-meters could within five years fit in very nicely, rendering 32 discrete channels. I see no problem in using this plan, then selecting a suitable deviation standard for one's own purposes. The equipment is made for either 5 or 15 kHz; anything else is a compromise in performance.

Six meters is less intensely used and 52.525 MHz seems to be the most popular for wideband operation. Narrowband operation does exist in some areas, from

51.0 to 52.0 MHz, on a 25 kHz channelizing plan. TV high-pass filters, though limited in effectiveness above 52.0, will help prove to TVI complainants that they often eliminate problems. AM operation stays low on 6 for reasons of self-preservation.

The 450 band is a world apart. Only the coordinators and trustees seem to know what really is in service and all admit there is more than meets the eye up there were channel frequencies are semiprivate. In Los Angeles as well as other places, for example, 50 kHz channelizing is the rule except that in L.A. ALL channels have been used above 440 and a coordinator tries vainly to keep accurate records. Those who prefer to go it alone find someone is sharing the space. Pairing is not in vogue just yet but efforts have been made to standardize, and several nets have adopted 5 MHz separation utilizing 440-444 outputs with 445-449 inputs. TV repeater experimenters have been a potential hazard, but recent concessions, after realization that FM'ers are serious, agreed to TV in the 435-440 portion of the spectrum. 450 is looking better each month as those who use this band for mobile operation see the value of planned pairing and reconfigure frequencies for better usage.

PAIRING

Armchair planning is always subject to criticism and rationalizing why it won't work. Moreover, existing nets complicate the matter. But let's look at what is being done in some areas and consider it for future planning in others.

	RELAY OUTPUT	INPUT
6 METERS	51.000	51.600
NARROWBAND	51.025	51.625
15 CHANNELS	51.050	51.650
	51.075	51.675
	51.100	51.700
	51.125	51.725
	51.150	51.750
	51.175	51.775
	51.200	51.800
	51.225	51.825
	51.250	51.850

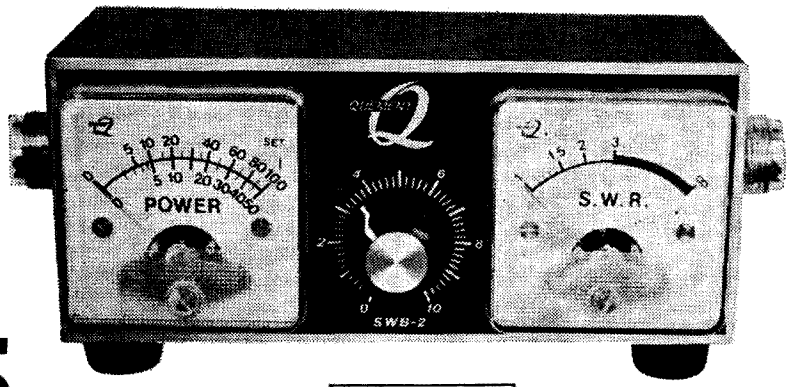
		UNPAIRED
2 METERS	146.610	146.010
NARROWBAND	146.640	146.040
13 CHANNELS	146.670	146.070
	146.700	146.100
	146.730	146.130
	146.760	146.160
	146.790	146.190
	146.820	146.220
	146.850	146.250
	146.880	146.280
	146.910	146.310
	146.940	146.340
	146.970	146.370
	146.400-146.580	
		UNPAIRED
	146.940	(GUARD
	51.275.	51.875
	51.300	(GUARD
		CHANNEL)
	51.325	51.925
	51.350	51.950
	51.375	51.975
	51.400 - 51.575	
		CHANNEL)
450 MHz	440.050	445.050
100 CHANNELS	444.950	449.950

This arrangement aims at compatibility with other amateur operation, best utilization of the spectrum, and extension of existing FM relay systems. It is placed in nomination as a national plan.

TONE

Overlapping repeater coverage on the same channels as well as the desirability of multichannel compatibility brings us to the realization that pulse tone must be standardized where used. If pulse tone entry is planned, choose standards and hold to this plan

Touchtone is gaining popular acceptance for control and signaling in some areas and probably will dominate as ability to produce good decoders becomes more widespread. This is an excellent approach for the more talented groups.



GUARD CHANNELS

Faced with the problem of where to establish a common meeting ground for members of various groups, each operating on its own discrete frequencies, the

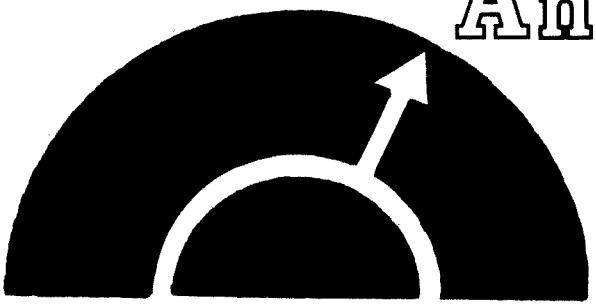
A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.



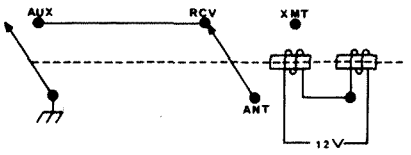
VANGUARD LABS

Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

idea of guard channels has become an acceptable solution and has proved successful where implemented. 51.3 and 146.94 are logical choices here, having been sanctioned by the California Amateur Relay Council as a regional solution. By guarding these channels or using a receiver scanner which samples more than one channel, a surprising flexibility is possible. By guarding one's regularly used channels plus the common calling and working frequency, we can provide ourselves with even better systems, both at home and while traveling.

The first eight years of repeaters has taken us through a period of organizing and building. Let's let the next eight be devoted to sophistication and joint planning. With good nonrestrictive repeater regulations a good possibility within a year a fine magazine to spread the word and cement us together, and the enthusiasm we all possess, the future looks promising indeed.

. . . WB6DJT ■



An Inexpensive RF Wattmeter

Walt Pinner WB4MYL
7304 Lorenzo Lane
Louisville KY 40228

While on vacation recently, I was rummaging through the various surplus outlets in the Detroit area. Among the goodies purchased was a small surplus "Antenna Current Indicator." It has a 2½ in. meter movement, three spring-loaded feedthrough connectors, and a power plug for connection to an internal antenna relay. It also includes the pickup unit and shunt necessary to operate the meter. The unit is a thermocouple-type antenna current indicator. Its nameplate states it was manufactured for the Army Signal Corps under the name of "Antenna Current Relay Unit BC442-AM."

The unit has a fitted bottom cover and ample room to install two SO-239 connectors in place of the feedthrough connectors already there. The antenna changeover relay is mounted to a plate and secured to the box with four screws. It may be removed as an assembly for use elsewhere. The rf contacts appear to be more than adequate for amateur use up to the legal limit of power. The rf contacts have an additional single-pole contact which may be

used for B+ control or grounding of the receive antenna lead during transmit, as shown in the diagram.

The relay is operated by two series-connected coils and requires +12V at 80 mA. If the coils are parallel-connected, a 6V source may be used. A single diode with a small filter on the rig's filament supply works nicely.

The meter scale reads from 1 to 10. Comparison readings of this unit, with no change other than substituting standard coax fittings, were made against a Drake W-4 wattmeter into a 50Ω dummy load. The results are tabulated below:

BC442 reading	Power (watts)
1	100
2	200
3	300
4	400
4.9	500
5.5	600
6.2	700
6.9	800

These readings remained constant over a range of frequencies from 3.5 to 30 MHz. Power levels of 25, 50, and 75 watts may be read with reasonable accuracy if the mechanical zero meter setting is adjusted with the meter in the vertical position and the power readings taken with the meter in the same position. The best part of this unit is its price. It was purchased from Bauer Industrial Supply, Redford Ave., Detroit, Michigan for $3.00, less his 15% discount (to anyone) which lowers the already ridiculous price to $2.55 plus tax. A terrific buy for your surplus buck.

E. Syracuse NY

A REMOTE MULTIFREQUENCY

A simple method for modernizing your surplus FM unit by adding those extra channels.

If your VHF FM gear is a single-channel type and you have been wondering how to add multifrequency capability, here is your answer. This article describes a remote crystal oscillator with switch selection of up to four crystals.

Since the original unit was intended for the transmitter of a GE pre-Progress Line ES-1B 2 meter FM unit, 3 MHz crystals were used. The circuit should work equally well with crystals of other frequencies (up to 15 MHz or so), and it can be applied to receiver local oscillators as well as transmitters. It is not designed to work with overtone crystals, however.

The circuit, Fig. 1, consists of a transistorized Pierce oscillator coupled to an emitter follower for isolation and low output impedance.

The oscillator unit may be mounted in any convenient location and coupled to the transmitter by a length of ordinary shielded cable. Neither the type of cable nor its length appears to be critical. In the original installation, a four-conductor shielded cable having a length of about 6 ft was used. The output impedance of the circuit is low enough to tolerate the shunt capacitance of 15 ft of shielded cable or coax without any drastic reduction in output voltage. Impedance matching is not necessary, since optimum power is not a requirement.

The rf output from the remote oscillator is fed directly into the grid of the former

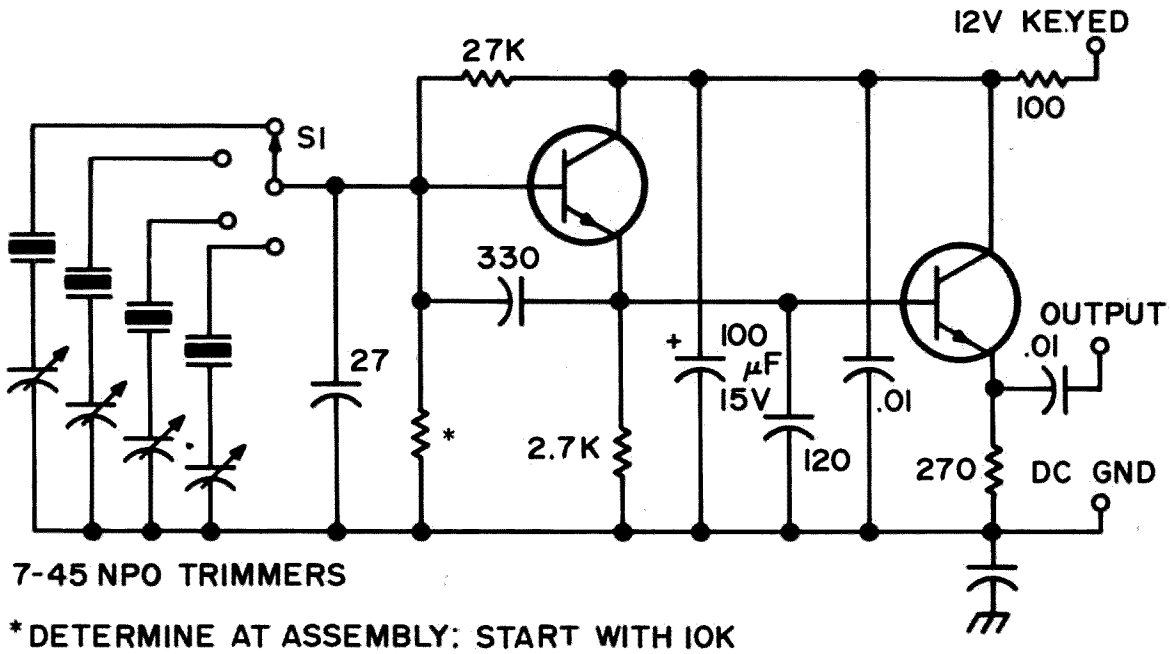

Fig. 1. Remote multifrequency oscillator schematic.

OSCILLATOR FOR SURPLUS FM UNITS

oscillator tube in the transmitter, so that this stage now becomes a buffer. The cathode of this tube (and screen, if a pentode) should be bypassed to ground for rf if not already done in the existing circuit. In my installation, the grid current in this stage was not as high with the remote oscillator as it was originally, but the drive level in the subsequent stages was unaffected.

The output frequency is not affected by the load, and changes only a few hertz when the supply is varied between 5 and 15V. Although the output voltage increases as the supply voltage is increased, the use of more than 15V is not recommended.

The oscillator consists of a two-board "sandwich" and a third board, which mounts perpendicularly to the other two, as shown in the plan view of Fig. 2. The actual size layouts of circuit paths for all three boards are shown in Fig. 3.

Once the etched circuit boards are made, assembly of the unit is quite simple. After soldering the components to the main circuit board (see Fig. 4), attach the output, power, and ground leads and mount the board in the Minibox. Be sure that leads and solder do not protrude more than 1/16 in. on the foil side of the board. Then attach and wire the connector (J1). Next, the rotary switch (S1) should be put in place and connected to the main board. The remaining two circuit boards with the crystal sockets and trimmers are fastened together and mounted last in the box. The front of this assembly is supported by the leads from the boards to the switch, so no size smaller than 20 AWG solid wires should be used for mechanical

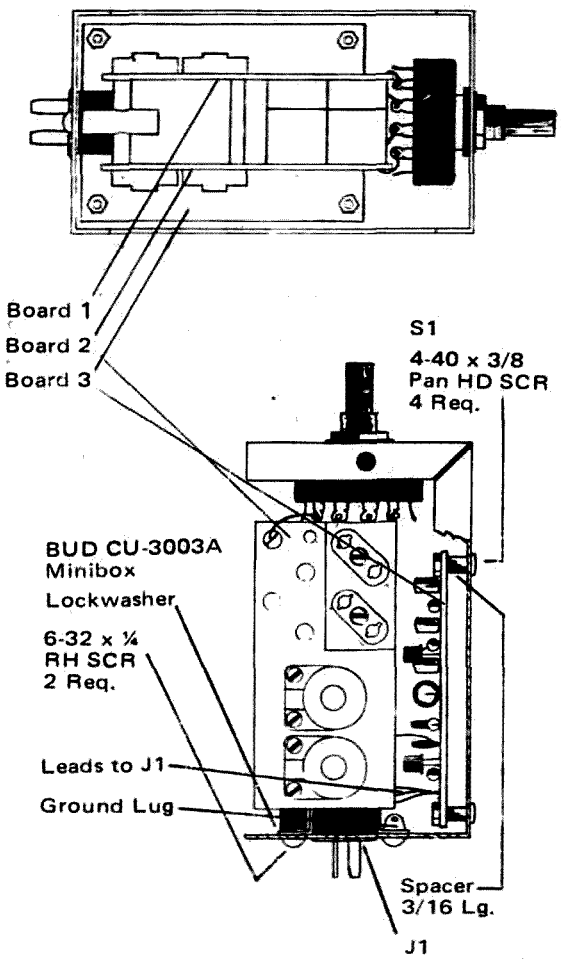

Fig. 2. Layout of oscillator.

stability. Use care when inserting or removing the crystals so as not to crack the circuit boards. Glass–epoxy board material is worth using, if available, because of its greater strength. Figure 5 shows the construction and layout detail for the two-board sandwich. When adjusting the trimmers for

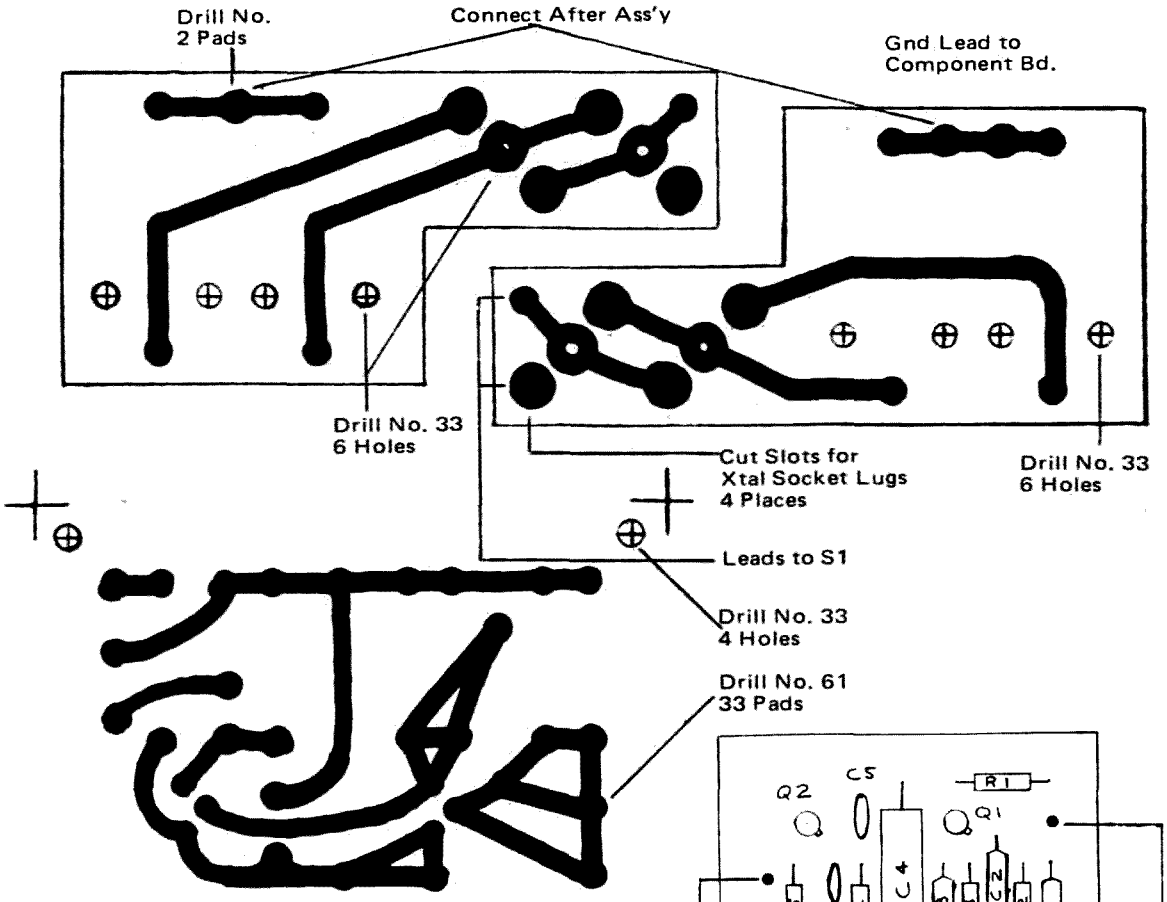

Fig. 3. Actual-size printed-wiring layouts for the three boards.

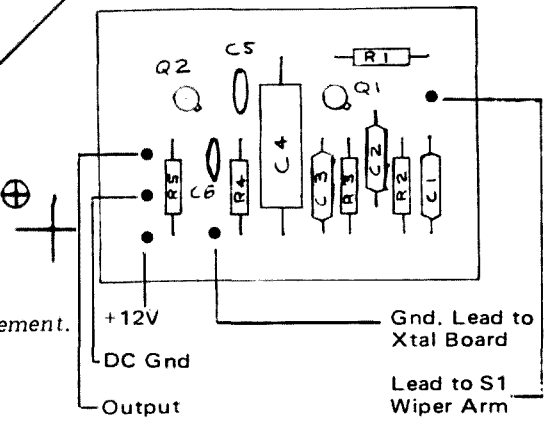

Fig. 4. Main circuit board component placement.

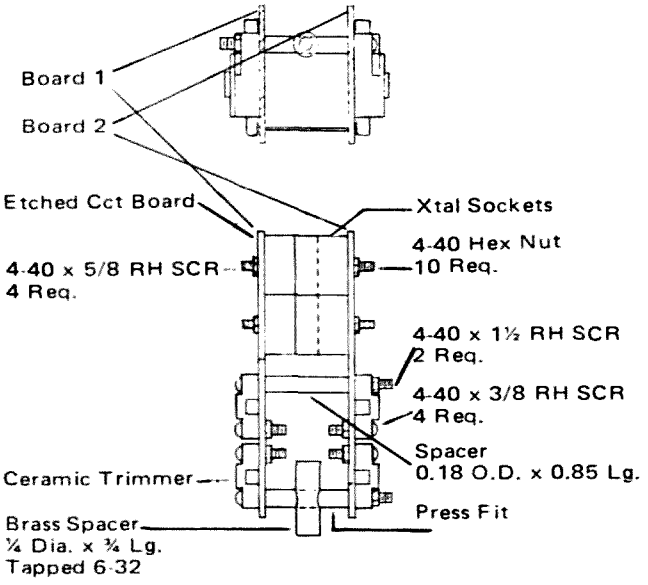

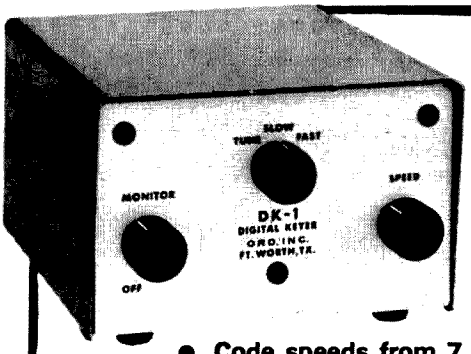

Fig. 5. Vital statistics for the two-board "sandwich."

exact frequency, remember that placing the cover on the box will lower the frequency slightly (10 to 20 Hz with 3 MHz crystals) due to the added capacitance. To avoid this problem, holes can be drilled in the cover for access to the trimmers. Because of its small size, the oscillator can easily be taken to a counter or other measuring equipment for accurate frequency adjustment.

Measurements of thermal stability have not been taken yet, but experience has shown that in the usual mobile environment the frequency does not change enough to be evident at the receiving end.

I am indebted to N. V. Friend, who furnished the idea for this device.

THE DK-1 DIGITAL KEYER

is designed to allow the CW operator to transmit morse code with a MINIMUM of hand motion. No other keyer exceeds the DK-1 in this respect.

● Code speeds from 7 to 60 WPM with correct inter-letter and inter-word spacings ● Mercury reed relay for transmitter keying and receiver muting ● Input for manual key ● Keying monitor with built-in speaker ● 18 integrated circuits, 12 transistors, 5 diodes

These examples illustrate the minimum hand motion required. The dot and dash keys may be closed or released in the order indicated within microseconds of each other.
"A"—Close dot-dash key. During the dot or dash, release dot-dash key.
"R"—Close dot-dash key. During the dash or second dot, release dash-dot key.
"P"—Close dot-dash key. During the second dash or dot, release dash-dot key.
"L"—Close dot key. During the first dot, flick the dash key. Release dot key during the last dot.
"B"—Close dash-dot key. Release dash key at any time during the three dots and dot key during the last dot; or, release dash-dot key during the last dot.
"Double Dash"—close dash-dot key. Release dot-dash key during the last dot or dash.

Note that in the above examples, only one depress-release cycle of the dot and dash keys is required. All letters, numbers and punctuation marks may be generated using variations of this technique.

ADD SPOTTING TO YOUR VFO

K. N. Gray K8BYO
1391 Schoolcraft Road
Copley OH 44321

To spot my vfo on a received signal, I needed a quick and easy way to power the oscillator independently from the transmitter.

Normally the ac-driven heaters are on all the time, so why not connect a 6.3V transformer in reverse order, rectify the output, and use it for low B+ for the oscillator?

After some experimentation, I came up with the circuit shown here. As shown, I connected a double-pole (single-throw) switch in both ground leads of the transformer primary and secondary windings to prevent feedthrough when regular B+ is applied as the rig goes into the regular transmit mode.

A diode in the B+ to the buffer prevents it from operating when spot checking and still allows regular operation.

TOWARDS AN IDEAL SOLID-STATE I-F FOR AMATEURS

PART 1 LOW FREQUENCY MODULES USING ICs

. . . and believe it or not, 455 kHz isn't it!

William Hoisington K1CLL
Far Over Farm
Peterborough, NH 03458

This article is a two-part series that deals with design methods, components, and circuits using solid-state devices leading to an i-f system that will meet the special requirements of the amateur builder who wants a reasonable-cost, selective, low-image, tunable i-f for use following converters on 6 or 2 meters, or the UHF regions above 420 MHz. This portion of the series describes design details of the 1.65 MHz and the 135 kHz i-f modules, using subminiature shielded coils and ICs.

Requirements

Selectivity and Freedom From Images. The easiest way for the homebrewer to get selectivity is to use a low intermediate frequency; however, this cannot be done without suffering from image trouble unless

several conversions are used. An image is the unwanted signal on a frequency separated from the desired signal by twice the i-f. This is caused by the presence in a mixer collector circuit of several frequencies other than the desired one. For example, if the local oscillator is on 28.5 MHz and the desired signal is on 28 MHz, a beat note at 0.5 MHz will be produced, which is used for the i-f.

Unfortunately, a signal on 29 MHz will also produce a beat note on 0.5 MHz. This unwanted signal is called the image; you can see that it can cause considerable strain on the selectivity requirements of the rf and mixer stages in a 10 meter receiver in order to remove it. This is one of the main reasons for multiple conversion amateur receivers that use a first i-f of 1.65 or 2 MHz, which places the image some 3.3 to 4 MHz away from the desired signal. Here it can be handled by the selectivity of the two tuned circuits of the rf and mixer stages generally found in such a receiver. The requirement for reduction of the image is met in this fashion in our "ideal" i-f.

Tunable I-Fs. The use of converters with crystal-controlled local oscillators for stability reasons requires tuning somewhere else down the line. For the fellow interested only in a large, stay-put home station, this can be accomplished by using his 100 lb communications receiver, with switched inputs, etc. However, that does not meet our planned types of operations, such as battery-portable-anywhere, mobile, and emergency use, all of which are applications well suited for solid-state devices. A tunable, selective front end with rf stages, mixer, and tunable oscillator does the trick.

Practicability. The next requirement is for available components at reasonable cost. The J. W. Miller Co. has produced a line of shielded, subminiature adjustable rf coils (9050 series) which fill the bill for inductors. They have a threaded core of powdered iron in the center for trimming, an outer magnetic shielding cup which also helps the Q, and an aluminum case for electrostatic shielding (½ in. square by 9/16 in. high). They also are handy because you can easily add extra windings—for coupling with solid-state devices.

Resistors in the 1/8 and 1/10 watt range are available at most mail order houses, along with subminiature capacitors. Subminiature terminal pins have been described in my own previous articles in 73 Magazine.

Active devices having high gain and low internal feedback, that do not need neutralization, are available from Motorola. The HEP 590 is one of these; it is easy to use and performs excellently.

Demodulation Characteristics. These articles being mainly concerned with AM on VHF and UHF, the demodulation is important. This is given scant treatment in many handbooks, but I find that when you're actually digging those call letters (at least!) out of the mud, you need the best possible diode circuit available. It seems, from all the tests I've made, that the diode demodulates more af when connected across the entire winding of the last tuned circuit.

AF Amplification. Next in order of importance comes a good af amplifier. There is no doubt at all in my mind on this one. The Amperex TAA-300 is it. It has 1W output, a response of 20 Hz to 25 kHz, and an 8Ω transformerless output impedance, and sounds good. With bass and treble controls in front, it really does the job for voice communication frequencies for amateurs.

Single-Package I-F Pair. The last requirement (for now) is for a double-frequency i-f. This is just a handy phrase for the combination of the 1.65 MHz and the 135 kHz i-f in one package. You can put more gain—with greater freedom from feedback troubles—into the amplifier when the input is on one frequency and the output on another—a tried and proved method.

I-F Considerations

Let's face it, 455 kHz is not the best i-f for amateur communications receivers. Its use as an intermediate frequency dates from the early 1920s which is by now nearly 50 years ago, and was intended for the broadcast band. There was and still is a good reason for using it on the BC band: It is the only i-f that even partially suits a "cheapie" BC set. I say only partially because using a mixer on the BC band, without an rf stage in front, which many millions of BC sets do, you get images from 540 kHz up to about

690 on the dial. I have a $100 set that covers 540 kHz up to 54 MHz—it is an excellent set for the money and is invaluable for checking harmonics, oscillators, mixer outputs, and the like; but not having an rf stage, it does have an image on the low end of the dial.

Car radios, mostly working on the "me too" design theory, use 262 kHz for the i-f. The reason given: "greater selectivity." Sure, it is easier to get better selectivity with a lower i-f, but the image is worse also, so they use an rf stage. If this rf stage is properly made and tuned, it solves the problem on the BC band. And I'll take my hat off to most of the designers of car radios that I've had, as most of these have performed pretty well. For many years of mountain-topping on 2 meters, driving home after 2 a.m., I kept awake listening to "Grand Ole Opry" and such, and those car radios did a good job.

But what about amateurs? These bands begin at 160 meters, so up around 10 meters, with an i-f on 455 kHz, the image is only 910 kHz away! You can't really put an i-f in the middle of the BC band, so the next slot is up at 1.65 kHz, or near that point. This works out fine for the image problem, but now your selectivity has gone to pot.

Of course, you *can* use a Gonset-type i-f with selectivity of around 30 to 40 kHz. In fact, right in this article I describe a "nice little i-f" on 1.65 MHz, with just that kind of selectivity. It works fine with just a single conversion on 6 or 2 meters, but when the band opens, stay away from the low end! I was in Maine one fine evening on a little rise of 400 ft or so when 2 meters opened. I worked Washington D.C. and VE1, but I couldn't separate one signal from another on the crowded low end using my "tried and true" Gonset III.

So, it is probably best to devote the extra time and money required and try for the ideal i-f, which conquers images and provides excellent selectivity at the same time. There are two components which help the home-brewer reach this goal: the Miller Series 9050 subminiature coils and the Motorola HEP 590 communication IC.

Our ideal i-f will therefore look like the block diagram in Fig. 1. When designed, components selected, the circuit formed up, and packaged with its small battery supply, it should be a useful addition to amateur VHF, UHF, and microwave equipment.

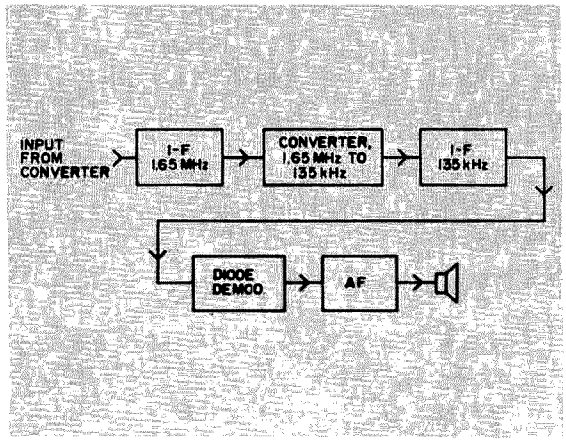

Fig. 1. Block diagram of the "ideal" i-f for amateur use.

Miller Series **9050** Coils

Here is something good, that you can really tailor to suit your needs. **Figure** 2 shows the inner workings. The Bakelite base is normally supplied with two pins, but is easily drilled for four extra wires (which you need for a link-coupled base input, for example). The coil form has a neat spiral ridge inside to take the 6/32 in. threaded

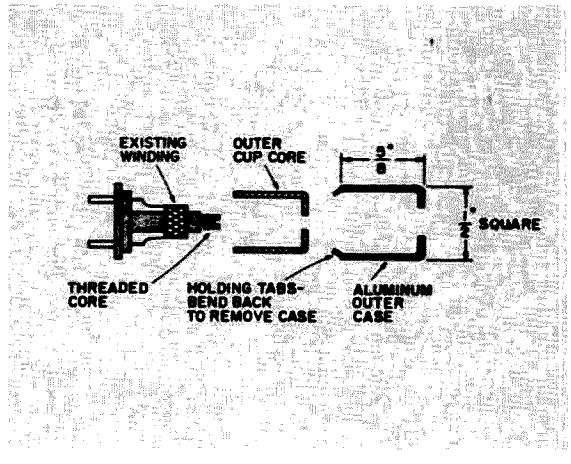

Fig. 2. Miller coils, 9050 series.

core. This ridge type works better than some other types of coil holders I've used. The outer powdered iron cup generally has room between itself and the existing winding for the few extra turns needed in solid-state work. The aluminum outer case comes off easily enough after you bend back the four crimped aluminum tabs on the case that hold the coil form in place.

As you will see in the section on coil data, you can wind on 1-10 turns of link coupling and a 5-turn base coil, both on top of the existing winding, for a base input network. I used a small drill to make more holes in the Bakelite end piece to bring out the extra wires, and find the entire series adaptable from 30 MHz down to 135 kHz; and the good Q resulting from the use of these coils is particularly noticeable in the overall selectivity figure of the finished i-f. **Figure 3** shows one of them with an extra

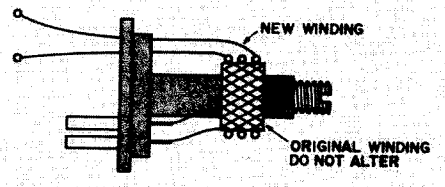

Fig. 3. Two holes at the bottom of the coil permit the two additional leads to be brought out with the original windings.

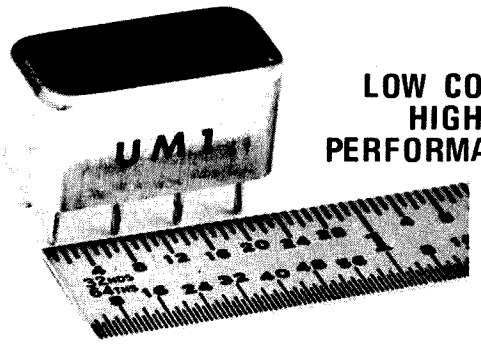

three turns installed. Until Miller comes up with something better, these are my coils.

Loaded Q vs Turns. Various sections of a communications receiver i-f have different amounts of loading, which affects the Q and energy transfer. For example, the HEP 590 input circuit works well with only a single-turn input link at 1.65 MHz, while at the same frequency a 5-turn link is required when going into the diode circuit, which is heavily loaded.

The HEP 590 output circuit, rated at 100 kΩ ac impedance, needs only 2 turns for maximum transfer of energy into a 50Ω cable or link to the next stage. Naturally, a lot depends on what impedance you're looking into, or out of, and how it is treated. The HEP 590 input circuit, rated at 1.8 kΩ ac impedance—if loaded directly onto the inductor—will swamp the Q way down.

Looking at **Fig. 1**, you can see what has to be done for this type of i-f. A winding of the correct number of turns to suit the impedance of the IC is installed over the existing tuned circuit, which is resonated at 1.65 MHz. A cable input link of only a single

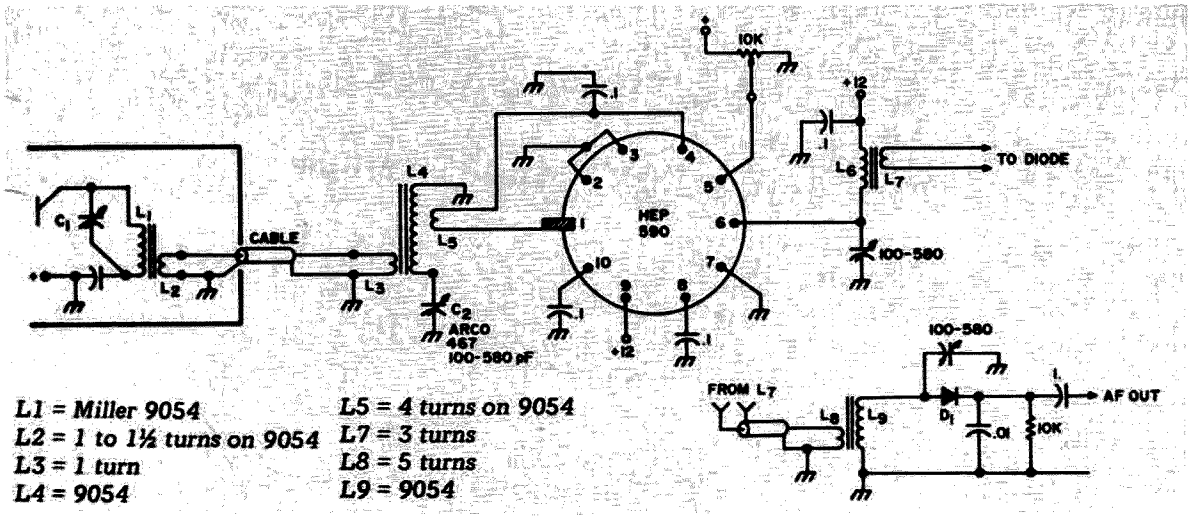

Fig. 4. Coil interconnection and winding data. At left is VHF converter (Part II). Test diode demodulator schematic is shown at lower right.

turn is also wound over the same resonant circuit. Don't forget that the presence of the powdered iron both inside and outside aids this coupling. When the inductor is heavily loaded and the Q is lowered, the number of turns required to effect a transfer of energy may be as much as five times greater. This can also be seen in the coil table in Figs. 4 and 7. The base input is very easy to match by this method of varying the number of turns, as in Fig. 4 (L4) and in Fig. 7 (L3).

When using link coupling, which is very desirable at times *with modulator type units*, be careful not to couple too tightly (by the use of too many turns). This will show up as excessive detuning of one tuned circuit by the one link-coupled to it. It may also cause broad tuning. For maximum selectivity and proper handling, use slightly *less* than the coupling showing maximum energy transfer. Remember, *gain* is cheap, *selectivity* is not.

The 1.65 MHz and the 135 kHz modules will be described in the first part of this article, and the converter and avc detail in the next.

The 1.65 MHz I-F Module

This unit is what you could call a "nice little i-f." Following a 6 meter front end, it has *plenty* of gain, and selectivity of 30 to 40 kHz. It is also very easy to tune on 6 or 2 meters.

The schematic is shown in Fig. 4. Each of the seven windings, L1 through L7, has been the subject of considerable work and testing here, for selectivity and general handling properties. The tunable i-f or VHF converter shown at the left is the subject of other articles and is not taken up here. It does use one of the Miller series 9050 coils, though, as shown for L1, with but one turn added on to it for feeding the 1.65 MHz i-f energy over to the i-f module being described. Inductor L2 is installed on top of the existing winding of the 9054 coil. Also low in turns is L3, with only one turn being needed at 1.65 MHz, due to the high Q of the 9054 design. Coil L4 is another 9054, which has a third winding going to the base of Q1 in the HEP 590 IC. The input of the HEP 590 is rated at 1.8 kΩ.

The input tuning of C2 is very sharp due to the correct amount of coupling to L4 which has a high loaded Q. The HEP 590 communications IC and its advantages have been described several times in 73 Magazine, so only a brief mention will be made here. Inside the IC there are three transistors and a diode. The two transistors that do the amplifying are arranged as in Fig. 5, in a grounded-emitter, grounded-base pair, which is a high-gain configuration with no detectable internal feedback. The third transistor is connected as an avc unit, and the diode is used for temperature control.

Another Miller 9054 is connected to the output circuit on pin 6 and tuned by an Arco 467 mica compression trimmer of 100 to 580 pF capacitance. You can also get the needed capacitance by using fixed dipped micas and trimming up to 1.65 MHz with

the threaded-core tuning slug. If you do it this way, be sure to adjust the fixed capacitors so that most of the slug remains *inside* the winding for best coupling and Q.

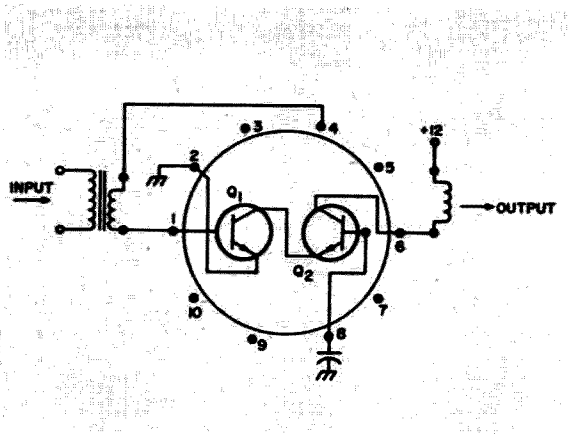

Fig. 5. Internal details, HEP 590, Motorola.

A 3-turn link winding is added to L6, which goes to an output connection. For tuning up, I used L8, L9, and a diode. When used with a tunable front end on 6 or 2 meters, this makes that "nice little i-f." Follow it with a good af and try it. You'll be surprised. It does not have ideal selectivity, but a 6 meter front end is wonderfully easy to tune with it!

Pin 5 of the HEP 590 can be used for a temporary manual gain control with just a

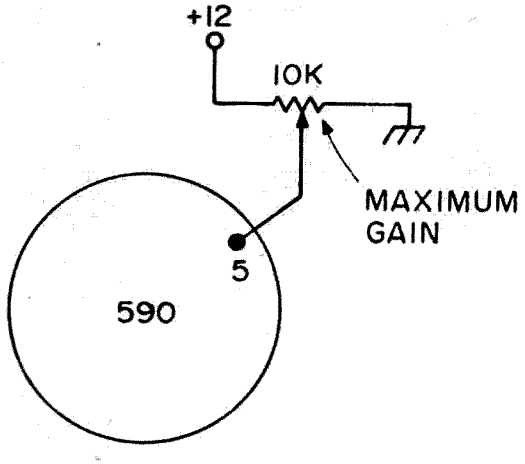

Fig. 6.

pot as in Fig. 6. Nothing else is needed. (The second part of this article deals with the avc circuit for use with pin 5.)

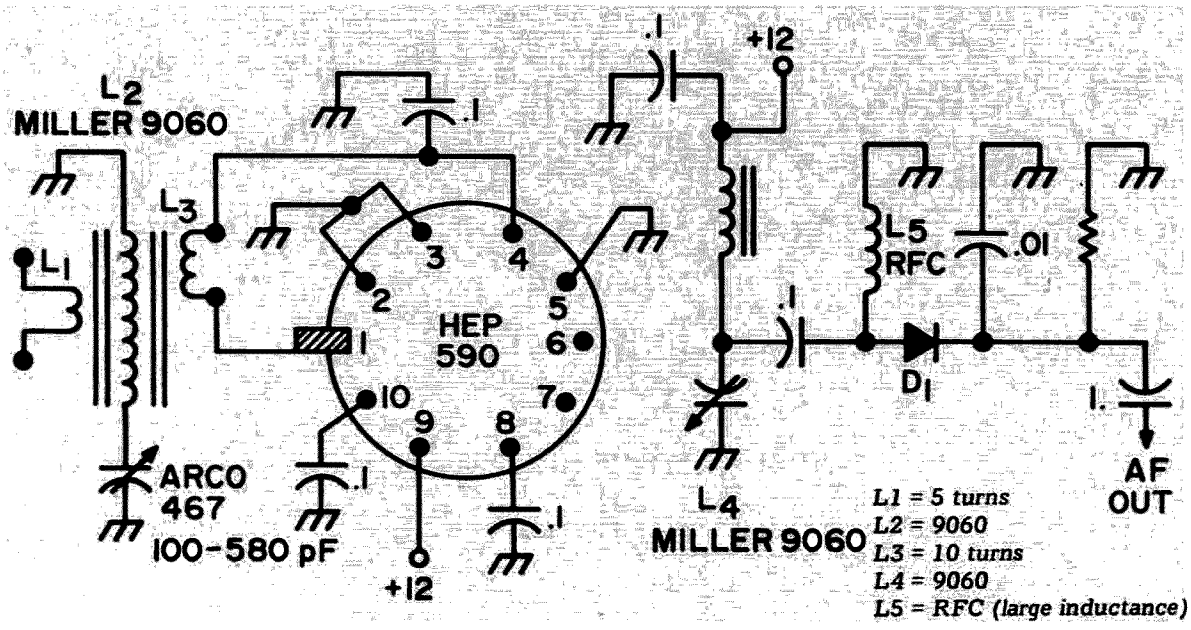
135 kHz I-F Module

My bypassing of the converter module to describe the 135 kHz i-f may seem abrupt, but the work involved with the i-f coils and the IC units makes the continuity better this way.

Figure 7 shows the schematic of this module using the Miller subminiature 9060 coils (with added windings) and the Motorola HEP 590 IC. The circuit is quite similar to the 1.65 MHz version except for the output.

The Miller 9060 tunes to 135 kHz with an Arco 100 to 580 pF trimmer, but here again you can make up the capacitor with the small dipped mica ones to bring the 9060 near resonance and trim to the exact frequency with the internal threaded slug.

The input cable from the converter module (second part of this article) goes to L1, a 5-turn winding installed over the existing winding of the 9060. I use 32 AWG double cotton-covered for this and put small tabs on the input wires of coil L1 for identification. You can also use different colored wire if you have it on hand.



The HEP 590 was described in the first i-f section. It is treated identically, except that pin 5 is left grounded, keeping the gain full on, which is best for avc action because this is the unit that drives the avc diode and needs full gain.

The output coil is another 9060, with the diode connected to the *high* end. Some circuits call for tapping down the diode on the coil, but I have never found any connection as good as that shown in **Fig. 7** for high quality af output. Only two tuned circuits are shown here but there is a third in the converter module; the total selectivity is thus as sharp as you may want to use, because you can still recognize your friends' voices on the air. It is sharp enough so that using it on 420, for example, I have been able to separate the audio of stations that were heterodyning each other. Of course those $600 receivers can have crystals and 2.5 bandwidths, but that isn't the class of machine we're building here.

This first part of two sections on trending towards an ideal i-f system has covered the 1.65 MHz and the 135 kHz modules using modern coils and ICs. The aim is to build the best i-f possible, using reasonable-cost components and homebrew methods. The difficult requirements of an i-f with very low image characteristics and very high selectivity have been met. The second part of this article details the converter and avc systems.

James P. Kirkgasser WA2ELA
105 Haddonfield Place
Dewitt NY 13214

The boys from Syracuse had a great time this summer doing something different. Of course, you have read about the idea put forth in 73 concerning Ham Hop, providing foreign hams places to stay when traveling about the U.S. We have already done something like this plus one better. We have set up "Ham Exchange."

This program is aimed at setting up hams going both ways, to Europe and to the U.S., with a home base that provides lodging and food at a ham's home. Thus, a traveler has a home away from home, plus the very important feature of cutting the daily living expense to the bare minimum.

The first test of the program was initiated by Fred Trode DL8VQ/W2, who enlisted the help of Uwe Rehage DL8QP to organize the DL side of the program. And we were off to our first and successful year.

Fred, my XYL, her sister, and four harmonics were the brave ones who met the charter aircraft at JFK airport at 3 a.m. on August 12 of last year. Of course there were the usual customs problems, including Eberhard (DJ9CJ) placing his passport in his luggage which went into the terminal when he needed it to get off the plane. After the normal fumbling in customs, the DL's were cleared at 5 a.m.

Fred crowded five of the hams and their luggage into his station wagon for the drive back to Syracuse where they met their hosts and the first ham exchange was off and running. My wife (Jo), with her sister and husband, took Eberhard and Ilse to see New York City and the one-time-only reception for the moon men. This was unbelievable as far as timing of the trip, etc., because our European visitors watched the Apollo XI all the way—including the walk on the moon (except Eberhard DJ9CJ), who fell asleep. I guess he had watched television eight hours straight and then pooped out at the first step on the moon).

A tour by sightseeing boat was perfect to get the feel of New York for our tired guests. Wall Street, Broadway, and the U.N. Building and two more days filled in the picture of New York City. Then we pulled the biggest goof in history—try and get through the traffic on the way to the first (hope the only one we have to go through) rock convention at Woodstock. Eberhard commented, "I have never seen so many cars boiling over in my life."

Once in Syracuse the variations on the exchange started. Some people wanted to travel, some wanted to work DX, etc. We had used 20 meters early in the summer to

NEW KRIS SCANNING RECEIVERS

Spectacular Monitoring with any one of 5 Kris Receivers

Own the ultimate in Automatic Scanning Receivers. The new Monitor Receivers enable you to lock-out specific channels and scan only the ones you wish. Automatically scans until a channel becomes active. Kris unit will then lock on the active channel and listen until the message is completed. When message is finished, the Kris Receivers will automatically resume scanning, skipping frequencies locked out.

Choose any of the Kris Receivers listed and just sit back and listen. No tuning knobs, no adjustments, no heat, and no service problems. Uses 2 FET's in the front end, all solid state construction for unparalleled performance. Use at home on 115 VAC or mobile 12VDC.

FEATURES

- Lock-out Switches
- Greatest Sensitivity
- Base or Mobile
- Stainless Steel Front
- 7 Channel Capability
- Better Than 1 Microvolt Sensitivity

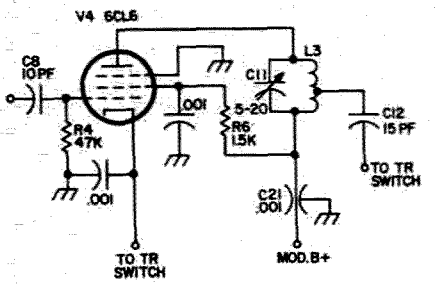
find out that travel was of most interest for Eberhard and Ilse. Boston, Niagara Falls, Montreal, New York City, and the local area were of prime interest. A trip was also arranged to Washington D.C. for Eberhard. Needless to say, we had a full four weeks.

I took a two-week vacation and combined it with the long Labor Day weekend to cover the areas outlined. We used a camping trailer for everyone including the children. This really cut the expenses and placed everyone in the person-to-person situation (where you can learn the most). One perfect Sunday was spent at Tanglewood, where we heard Erich Leinsdorf conduct the Boston Symphony in Beethoven's Ninth Symphony (Ilse's favorite). This is the main point about "Ham Exchange"—the people involved set up their own programs. Some traveled, some used Ham Hop, some sat home and drank beer and just got to know people.



So this is "Ham Exchange." Write your own ticket! Travel to a new land! We will help find a ham at the other end who will provide a place to live and food. The rest is up to you and your host. We hit the road and covered the northeast quarter of the

United States. Out of pocket, it cost us about $350 overall for one month, which included a vacation for our family and two additional weeks including New York City, Niagara Falls, etc. For the fun we had, and for six people, this was quite reasonable. Now we are ready for next year, and we are planning our trip to Europe with our two children.

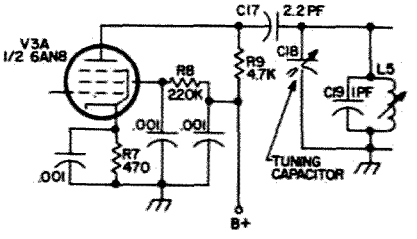
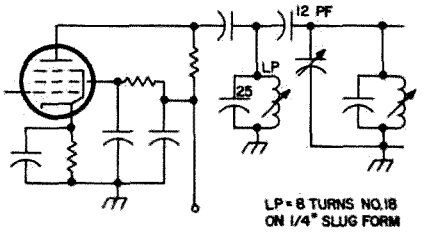
Unmodified Sixer final amplifier.

SUPER SIXER

. . . to the rescue



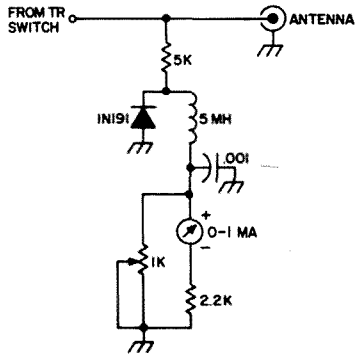
Modified Sixer final amplifier.



There's just something about a Sixer that can drive a ham crazy with "modification fever." Have you ever noticed the number of improvement articles written on them? It was a touch of such a "fever," induced by TVI, that got me digging into the bowels of my Sixer.

TVI has a bad way of catching up with you, sooner or later. Naturally, it wasn't too long after the little rig was first put on the air that a flood of complaints of television interference began. The use of a lowpass filter was obvious, though I couldn't bring myself to sharing the kW filter on the sideband rig with such a peanut whistle of a tranceiver. Why, the filter looked as large as the Sixer! There must be some other quick way around the interference...

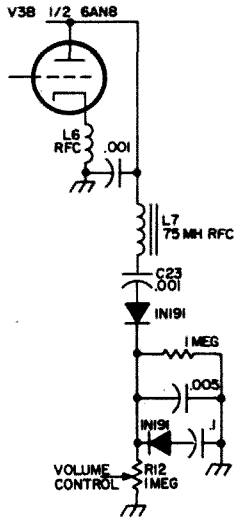
On the premonition that C12 (15 pF) in the plate tank circuit was passing something other than just 50 MHz to the antenna, I changed over to link coupling. L3 was cut down to 6 turns and another coil of insulated wire, LX, of 2 turns was wound over it.



Unmodified Sixer receiver, rf stage.

Modified Sixer receiver, rf stage.

The results were amazing. The TVI was not only gone, but in addition, the transmitter loaded into the antenna better. This was great, so other modifications were begun.



Improved tuning system.

Two holes were next drilled into the front panel, one to mount the new load control, and another for a capacitor to tune the plate of the final (6CL6). Two 0-100 pF variables were used because they were on hand at the time. The plate variable was placed in series with a 15 pF capacitor (the former C12), to make the tuning less critical at resonance.

Next, the grid and screen resistors of the final were changed from 47K and 1.5K to 10K and 1K, respectively. Input power increased two watts. Now some form of visual indicator for tuning the transmitter was needed. The original relative power output measuring arrangement of the Sixer leaves a lot to be desired. With a small light bulb as a dummy load, you can actually see a decrease in power when a meter is inserted into the circuit. A better, less lossy arrangement was substituted to sample the output rf. It is then read out on a 1 mA meter that was installed on the front panel.

Just for fun, a neon bulb was soldered in series with a .001 μF capacitor, and then to the cold side of L3. Instant modulation indicator.

The receiver section of the Sixer is its weakest spot. While the sensitivity is good, the selectivity is too broad to be usable when the band is crowded. A certain degree of selectivity was gained by adding a tuned circuit between the rf and detector stages of V3 (6AN8). How much selectivity was added, is hard to determine, but stations tune more sharply with less overload interference now.

Noise limiter.

Since the ultimate aim was to use the rig in a car, a noise limiter was tried. Even with the good limiting action inherent to a regen receiver, ignition noise was still a problem while operating mobile. From the Diode Handbook (73, Jan. 1968) came a circuit for a shunt diode noise limiter. One was installed between the detector and the first audio stage. Nothing truly spectacular resulted, for the ignition noise didn't disappear. It was reduced to a more tolerable level, however.

The crystal socket was moved to the upper right hand corner of the front panel. Instability was avoided by installing a tube shield over the 6CL6. And last, a 4PDT relay was wired in to allow PTT operation—a must when you're mobile. The Sixer was a nice rig to begin with; it's even better now.

Bob Manning K1YSD
Box 66
West Rye NH 03891

Bob, Bob, Bobbin' Along

K1YSD beside himself beside himself beside himself beside himself beside himself beside him

"This is K1YSD—mind if I get in on your roundtable?"

"Come aboard! What's the handle? Handle here is Bob!"

"It's Bob here, also!"

"Good enough, we got Don K1QES and Don K1NDA, and also another Bob WA1ACH on frequency."

"Oh swell. Say, Bob, what's your QTH?"

"Which Bob?"

"AOH."

"Mugwump Valley—but Don's got the best location."

"Which Don?"

"Whaaaaa me?"

"Me?"

"Who me? You call me? I was out in the sandbox."

"Who's this?"

"Don!"

"Which Don?"

"QES. Who's this?"

"Bob!"

"Which Bob?"

"YSD. Who said that?"

"Said what?"

"Said, 'Which Bob?'"

"Me, Don!"

"Which Don?"

"NDA!"

"Hey fellas, can I join the roundtable? My name is Herschel!"

"Herschel?. . .Herschel!!! You bet your sweet Aunt Matilda's hand knitted antimacassar you can join! Fact is, we'd appreciate it if you took over as the moderator of this group. Here's the situation as it now stands: We have three Bobs and two Dons on frequency. We can simplfy it if we label TFC as Bob 1, AOH as Bob 2, and YSD as Bob 3—then label QES as Don 1 and NDA as Don 2. Now, Bob 2 wants an informal with Don 1 and Bob 3 wants to talk to Bob 2—he has a message from Bob 2's son, Bob Jr. 4—Don 1 wants words with Bob 3 about what Howie 1 said to Howie 3 and Harold 2 about Don 2's meeting with Bob 1.

"Have you got all that Herschel?. . . Herschel!!!. . .Herschel???. . .Now, where the devil did he go?"

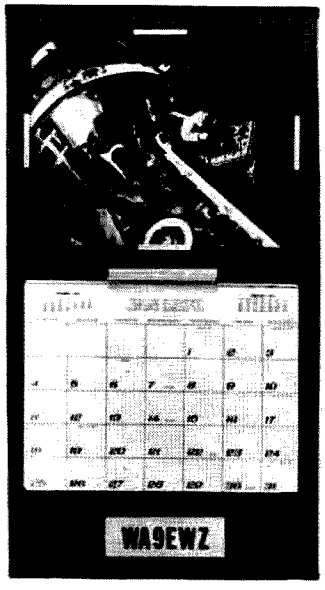
"I think I heard him mutter something like, 'Good Lord, I've tuned into the 'intra-happy-home-net' just before he pulled the plug!"

"Who said that?"
"I just told you, Herschel said it!"
"Yeah, but who are you?"
"Don!"
"Don who?"
"Number two—who's this?"

At this point something must have snapped, for the next thing I remember is clawing frantically through the metal and cloth grill, reaching in and disemboweling my MS-4 speaker (turning a $20 speaker into an 89¢ *frisbee*). Then, standing fully erect, and with all the force of a Paul Bunyan with prickly heat, I cleaved my Drake R4 into

two equal parts with my boom mike (giving myself two R2's, a chromium W.C. Fields cue stick and a possible double hernia).

Shrieking, "GERONIMOOO!!!, I hurled myself through the screened window—straining myself—counted ten and pulled the "D" ring which, as luck would have it, happened to be the snap fastener on my sansaband trousers, and went stomping down the by-ways of our otherwise normally quiet New England town, clad only in a terry cloth robe, knee socks and boondockers with a pair of earphones clamped on my head, from which dangled, 'twixt my knees, the earphone cord and ¼" phone plug, resembling either a grotesque umbilical cord or some other potentially hysterical physical malformation . . . still clutching the misshapen boom in my hand. (I still wake up nights with the memory of a wild-eyed, horny, but impotent shepherd clomping and frolicking ungainly—not unlike a rhinoceros in heat—down the road to the tune of "Hippity Hop to the Barber Shop.')



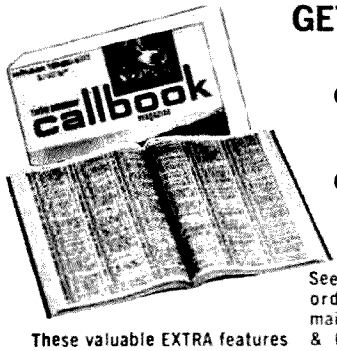
I kept up a continuous chanting mumble of, "I'm Bob, no—you're Bob, I'm Don, he's number two, you're Don, he's Bob, I'm number one—Herschel! Herschel?? *Who the hell is Herschel??*"

I might well have gone on like this forever and, since it was summer, there's a good chance I'd have reached route #1 (Blood Alley) and been scrunched into unrecognizable mush by some boat-hauling, arm-dangling, gum-chewing, antique-collecting kamikaze driver from Massachusetts, possibly adhering to one or more of their treadless retreads (though this would have made me a big man in concentric circles, I must confess ,that I had no real desire to become a permanent part of the Spaulding Turnpike).

Every summer, these juggernauts—with the instincts of the suicidal lemming and the finesse of a "dropped rock," burst into our State like mindless shrapnel from a fragmentation grenade.

They come, on their annual pilgrimage, like a horde of soldier ants, or locusts, firm in the belief that not only is the shortest

New Personalized Station Calendar



Dress up your ham shack with this exclusive appointment calendar wall plaque. Full color Apollo glossy photo, 1970 calendar, your name or call personalized on metal plate, all attractively mounted on walnut plaque. Nets, Skeds and Contests can be noted one month at a time. Size 11½" x 22". Mounting hardware included. 1971 replacement calendar available this fall. Only $4.75 ea. plus 75¢ for prepaid postage and handling.

distance between two points a straight line, but that the Massachusetts plate gives them license to disregard any and all safety precautions and that nothing should—indeed, nothing could—stand in their way.

Ensconced in a formless, unidentifiable 2000 pound mobile pig-sty, held together by Band-aids, inspection stickers, rusty wire, primer paint, ding-a-ling decals and a modified law of inertia, which, in this case, states that the vehicle—once set in motion—must not only remain in motion, but must do so with ever increasing speed mathematically proportionate with the distance covered, accidents caused and terror instilled in New Hampshirites. Failure to comply will result in instantaneous disintegration, creating either a 'Susan Spotless NO! NO!' or a new ski area complete with 200 foot bar.

Dragging a crusty, fish-tailing old boat behind, pushing a huge bug screen in front

and carrying, overhead, what appears to be next year's entire work load for the Goodwill Industries . . . at the wheel, a wild-eyed nut with at least one loose screw, a skaggy old bag and half a dozen sticky fingered, rock throwing kids with lollipops stuck in their ears and a howling mongrel dog slowly being strangled by 127 feet of 'Discover America' banners . . . they steam roll over stop signs, traffic lights, back yard fences, dogs, cows, kids, pedestrians, historical monuments and especially other mobile pig-sties. (Quite

often they are fired on by irate New Hampshirites and occasionally even by the Welcome Wagon.) All this in search of a pool of stagnant water (even a backed up septic tank will suffice) in which to launch their 22 foot boat (?) with twin 50 hp motors, an antique shop from which to buy a piece of driftwood, a broken rocking chair, a two legged buffalo milking stool, some genuine Indian artifacts (made in Hong Kong) or a hand painted lobster claw with 'Souvenir of Kankgamangus by the Salt Flats' painted on it, or to find some picnic/rest area where they divest themselves of a year's accumulation of HoJo cups, napkins, straws, half eaten Texas-burgers, glad bags and other assorted garbage.

The contamination record (presently held by a family of four) is 2 minutes 19 seconds to turn a picturesque rest area into a mess that has all the charm and beauty of a blighted and deserted land fill project.

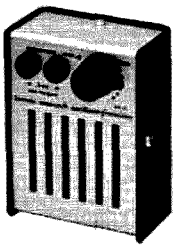
Fortunately, however, I was saved from exposing myself to this danger when I was suddenly blocked by a taxi which pulled up in front of me. The driver, noting my garb and hearing my mumbles, quipped, "Need a lift to Foam Rubber City, Buddy?"

I sped around the cab to the driver's side, reached in, grabbed the driver by both lapels, shook and twisted and shook some more while screaming hysterically, "What's your name, What's your name? Just what the hell is your ruddy name?"

"Lillian! Lillian!" she gagged, "What's yours?"

"It's Bob," I replied, "No, it's Don—no, it's Howie—no, it's Herschel—I dunno—maybe it's Lillian."

She swung her dashboard mike like a bolo, catching both my hands and causing my thumbs to become jammed, one in each ear like deer horns (if it had been winter, I'd have been gunned down by a leaky booted Massachusetts hunter carrying a modified bazooka firing 88mm flare rockets). As she careened round the corner, and out of sight, I had the final satisfaction of seeing her hair turn white.



If you're reading this, I'm assuming two things not necessarily in evidence: One, that you have some sort of interest in radio and aren't just an itinerant kleptomaniac that absentmindedly scooped up this magazine as part of your daily quota and, two, that you know what a 'handle' is.

A 'handle,' besides being the mechanical accoutrement for lifting a pot, teacup, or thunderjug, is also, for some inexplicable reason, the coloquial idiom used in amateur radio by the Neanderthal ham in-group as a synonym for the name, 'name'; i.e. 'handle' replaces the name, 'name.'

The apprentice/greenhorn ham (or 'tongue-tied jerk' as he is ofttimes unfairly referred to) just breaking in and, not wishing to sound like an idiot, which incidently, is practically an impossibility on today's bands—it has long been my contention that you could recite any arbitrary exerpt from such books as, "The Orthopedic Surgeon Looks At Your Mattress," "The Abnormal Sex Life of the African Tse Tse Fly" or the prologue to "The Cause and Effect of Rampant Fungus on the Yucatan Peninsula" backwards, in Sanskirt or Pig-Latin and no one would think it strange, probably replying, "Roger O.M. Fine Business—I agree—I got a doublet here fed by 600 ohm twin line etc, etc., C.U.L. . .anyway, not wishing to sound like an idiot, the apprentice invariably slips into the 'dead sea scroll' word, 'handle.'

However, the younger generation—as it gains confidence and wishing to show its individuality and create its own neo-radiophyte in-group—has started a crusade to substitute the word 'name' for the word 'handle' which, of course, means 'name.' Consequently, if you wish to be of the modern in-group, you'd say, "My name is Bob!" Translated into Cro-Magnon ham lingo, this would mean, "My 'handle' is

mark2
oscillator/monitor

- makes an audible tone to monitor the RF of any CW transmitter from 10Mw to 1 Kw & 100Kc to 1000Mc, using only an 8" pickup antenna.
- can be self-triggered for code practice or the testing of solid state components and circuits.
- aids in tuning up & testing RF oscillator and power circuits.
- 4 transistor, 2 diode circuit, speaker, tone adjust, AA pencell, test tips, 8" ant., & magnetic base.
- cabinet is 16 gauge black & clear anodised aluminum, 3.4 x 2.3 x 1.2"

Bob!", which, translated into English, would mean, "My name is Bob!"

Logically, it should follow that when you say, "My name is Bob," you in reality mean, "My name is Bob!" but this, by antiquated League standards, is not only totally ridiculuous and ludicrous, but downright sacrilegious! (This transgression may be forgiven if you immediately yell, "Hail Huntoon et tu Hart" ten times while ingesting the first fifty pages of the Handbook, having "I LOVE I.C." tatooed on both pectoral muscles, or goosing a non-League member with a hot soldering iron.)

I might also add that the younger—or upstart—generation, as a further impiety, is attempting to do away with speaking CW phrases on the phone bands . . . damned kids. The CW advocate when switching to voice retains a lot of the CW colloquialisms such as "Q" signals. Ever try to talk in "Q" signals? At best it's like trying to pronounce pharmaceutical conglomerations while sucking three jaw breakers underwater with a split palate.

You can get away with 'cue-so' for QSO and 'Q Street' for QST and Quirt for QRT, but you're gonna rupture your larynx pronouncing QRP, QRO, QRV, QSL and QTH (Quith?).

The opening dialogue may have sounded unreal, but tune across 75 meters any evening and ye shall find the truth.

I've been net control on many occasions when there were four Bob's, five Don's, two Bill's, two Walter's, three Howie's and two Ed's. Occasionally, however, you'll run across a Vladamir or a Katrina to break the monotony and keep you from turning 23-year-old female taxi drivers into white-haired old ladies on a daily basis.

[Funny my mentioning Katrina. Poor ole Katrina—she recently ran amuck when some good intentioned neighbor, thinking that the name 'ham' applied to the male of the species only, called in an ITVI complaint and called her a 'sow.' Katrina took immediate affront to this, cornered the caller and

force fed him a mixture of 2 pints of milk of magnesia and 1 pint of vodka (the world's second largest Phillips Screwdriver).

Katrina was brought to trial, convicted and sentenced. Now, I don't know your feelings about capital punishment—in this State the maximum penalty is hanging—but, by golly, I just don't believe a woman should be hung like a man!]

Since the age span of any arbitrary group of clustered hams may range in years from 20 to 70, it is, indeed, a weird phenomenon that you'll find a sickening repetitive duplication of names. It gives one pause to wonder if, by some E.S.P. or precognition on the part of the parents that their offspring would end up being hams, they, through either a singular lack of imagination, some secret sense of humor, bestowed a seemingly endless string of common, lackluster names on all hams and hams to be.

If you were to recognize any ham by his upraised joystick or slipstick or notice him mounting his hustler, accost him and ask him—point blank—what is *the* most single important item in his shack, he'd like as not

reply, "The receiver, or possibly the antenna." This is a malicious rumor spread by the same group that sponsored Edsels, slipped amateur radio the purple shaft with oatmeal clusters by turning 50% of the ham bands into a vast wasteland, and that is trying to give 10 meters to the CB'ers.

Let me assure you with a conviction born of frustration (mental constipation) that the most important item in your shack is your name and you will be saddled forevermore with the first name you give on the air.

If you've been cursed with a common name, then by all means adopt a *nom de plume* (pen name, for you illiterates).

Selecting the proper 'on-the-air name' should not be handled lightly. Television—especially late night movies—offers the most versatile virgin land for procuring a name.

Horror: Bela, Boris, Igor, Krag, Zandor, Mandrake, Luthor, Kral.

Cowboy: Wyatt, Duke, Matt, Knobby, Windy, Bat, Tex, Bret, Bart.

Ancient: Mars, Herc, Eros, Ajax, Thoth, Vulcan, Cronos, Thor.

War: Sarge, Gunner, Chief, Buck, Cap'n, Doc, Tex.

Misc: Kelly, Sully, Murph, Tab, Ty, Rip, Dash, Rock, Torn, Sue (?).

Just remember that, in real life, every Tom, Dick and Harry is named Tom, Dick and Harry, but in ham radio I've found that every Tom, Dick and Harry is named "Bob!"

One word of caution. Don't get too cute or you could end up like this:

"Name here is Spiro T."

"Spell it!"

"Spiro T—Sierra Papa India. . ."

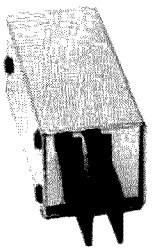
"Whazzat last?"

"India—India November Delta. . ."

"Whazzat last?"

"Delta—Delta Echo Lima Tango. . ."

"Whazzat last?"



"Hell, I dunno—what am I spelling anyway? Who am I? What's my name? What's my name? It's Bob, no, Spiro T. I'm number one—you're Don, Quirt Quirt cue-ess-why Quirt WWAAAA—HOOOOOOO! Run for the hills, Lillian, HERE I COME AGAIN. . . GERONIMOOOOOO!!!"

"Look out for that guy wire!"

"What guy wiiiAAAWWWKKK??"

DUAL GATE MOSFET
PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

THE DIP LIGHT

Have you ever wondered how the grid dip meter got its name? I think it is self-explanatory to a certain extent, indicating that there is a meter in the grid circuit of a tube and that it measures the dip in current that occurs as the energy is absorbed when the oscillator tunes to the same frequency as the circuit under test. The name is all right as long as you think in terms of the tube circuit, but in recent years we have been seeing circuits using transistors and tunnel diode oscillators taking over. In other words, no grids.

So now the name has changed to "dip meter," which is fine as long as you have no objection to the meter part. As I see it, the meter has done a very good job in the past on this instrument, but nowadays we can come up with devices not limited by the constraints imposed on the people who first developed the grid dip meter. Think of a pilot light bulb, for instance. How much better it would serve the purpose, since you would not have to concentrate on it to see a dip as you would with the meter. Many times as I stared at the meter (which happens to be at the opposite end from the coil), I would find that I was getting no dip simply because I had inadvertently moved the coil away from the circuit under test.

A light bulb is much more obvious than a meter needle, and in this use you really would not need the precision that a microammeter gives. All you really want is a dip. A light bulb is just not sensitive enough to read microamperes. But what if you were to help it with a couple of transistors? This is the crux of the dip light shown in **Fig. 1**—the little devil that will do everything that a grid dip meter will do, only better. And it can be built more cheaply, to boot.

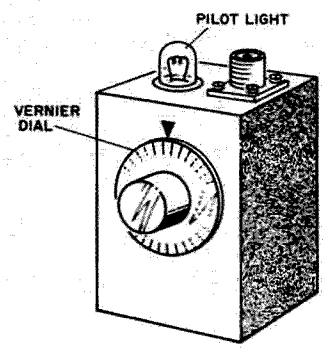

Fig. 1. A vernier dial on the front of the unit can be calibrated without much difficulty. The bulb itself can be held in place by cementing it to an ordinary grommet.

Construction

You can use regular coax connectors for the coils and build the latter on a stub of coax about 3 in. long, with the connector at one end, the outer cover and shield peeled

back as shown in Fig. 2. The coil is wound on the plastic core, soldered to the center conductor and shield and then covered up with GE crude rubber cement, which is quite soft and flexible even after having cured.

The indicator lamp should go somewhere near the coil, where you can see it and the coil at the same time. For the frequency readout I used a small calibrated vernier drive. You'll find this easier than making

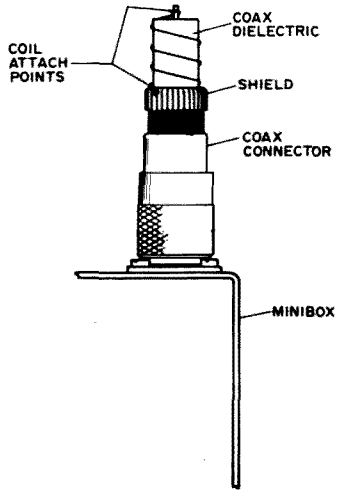

Fig. 2. Coils can be built onto bits of RG-8/U cable and terminated with UHF connector.

your own dial, and you can use a chart or set of curves to correlate frequency with the calibrated increments.

For the tuning capacitor, use an APC with a ¼ in. shaft. Mine had some plates removed, but I would guess it to be about 30 pF.

The oscillator circuit happens to be my pet one, but since it is not critical, you could use your own circuit. It occurred to me that one could open up one of those two-dollar modules sold as FM wireless instrument broadcasters. At least one that I know of is not encapsulated in epoxy. I built my own (Fig. 3) with GE9 transistors and have no trouble getting this little gem to oscillate up to 120 MHz.

Capacitor C1 should be chosen to oscillate down to the lowest frequency to be used. My unit worked well with a 55 pF capacitor. Resistor R1 should be 100 kΩ initially; then, when you have finished building you can replace this with a 0.5 MΩ temporarily, adjust this for a good indication on your lamp (I set mine for maximum rf, but don't know how good this might be for the transistor), and then replace with a fixed value to correspond with the setting of your pot. The lamp amplifier is a Darlington circuit to provide a better load for the diode circuit, but you could use a one-transistor circuit almost as effectively.

Be sure that you use high-gain transistors in either case though; they should be medium-power "driver" types to handle the current required to light the lamp, which should be a low-current one such as the 48 or 49 bulbs (coded with pink beads). Use two penlight cells for power and you end up having a really versatile instrument.

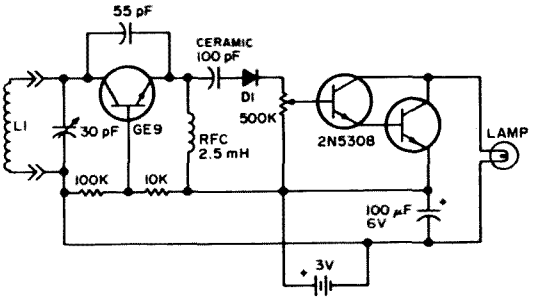

Fig. 3. Dipper is nothing more than a simple oscillator and a Darlington amplifier pair.

Plotting the Frequency

Making the frequency curves should be a simple enough matter using "science" graph paper and an accurately tuned receiver. Simply tune the receiver to the frequency that you need then find it with the frequency control of your dipper. First find the highest and lowest frequency that the instrument will cover, and mark this along the side of your graph. Mark the maximum number of divisions of your dial along the bottom of the graph. Then spot a few frequencies more or less evenly spaced between the maximum and minimum, and draw your curve to touch all the points. Voila! You have a curve for one coil. Repeat this for the others. This method is good because if you ever wish to make an extra coil, you simply make an extra frequency curve for it and do not have to alter your instrument at all.

. . . VE3ECU/WØ■

73 Checks Ont The KRIS Scanning Receiver

One of the most interesting technological innovations in recent ham radio history has been the "scanner"—a transistor FM receiver that has the capability of monitoring a multitude of crystal-controlled channels by sequentially scanning the frequencies at a high rate then stopping and "locking on" to a frequency where a signal is present.

The idea of scanning is not new; there were a number of military "autoscan" receivers in use during the second world war—but these were large and cumbersome, they used mechanical contrivances for slewing, and they tuned at a rate so slow that short-duration transmissions could take place without being spotted. Today, with more and more frequencies being "standardized" for repeater operation in the VHF bands, the scanning receiver takes on more the stature of a necessary part of a truly "mobile" mobile setup, and less that of a conversation piece.

In the New England area, for example, where repeaters stud the hilltops, a user who wants to get the optimum use from his equipment will have to be prepared to transmit and receive on as many as four repeater frequencies—in addition to those frequencies established as "point-to-point." The problems of monitoring for activity can become trying when you pass through areas where several repeaters—on different frequencies—are operational. I found myself monitoring 146.94 MHz for signs of action on the W1ALE repeater while the Mount Snow and Concord machines (146.88 and 146.76, respectively) were hopping. A scanning capability, I felt, would serve as a "funnel" and allow monitoring of all the repeaters and point-to-point channels at once.

So that I could check out the practicability of monitoring with a scanning receiver, I invited the manufacturer of the Kris scanner to lend me a unit for a while for test purposes. I had seen Kris' ads and was frankly impressed with the specifications. The people at Kris were accommodating, and provided a receiver that was tuned up, crystaled, and ready to go.

I was in for a few surprises when I opened the box. The ads I had seen on the Kris units had been for the "Snooper," a

$139 unit with an "automatic–manual" switch for mode selection. But what I received was the top of the line: a $149 receiver with a built-in switching capability that permits the operator to "lock out" any channels he does not wish to monitor. Also, I discovered that the unit is not restricted to mobile use; it comes with a built-in power supply to permit use from either 115V house current or the 12V power from a car battery. It also comes with a removable telescopic whip antenna that attaches through a grommeted hole in the cabinet top.

On the negative side, the regular antenna connector on the back of the scanner is made to accept the plug that comes standard on automobile BC radio antennas. This might be great for someone who wants to forego his mobile BC listening in favor of monitoring the local FM nets, but for most of the hams I know, it would be an annoyance. The ideal connector, in my estimation, would be a conventional UHF connector suitable for matching with regular RG-8 or RG-58/U coax. It is probably safe to assume that the unit was originally developed for use by off-duty civil employees and other nontechnical people who would be stopped by so strange a beast as a PL-259 or its mate. At any rate, the required adapter is an Antenna Specialists M46; and the Kris people indicated they would supply the adapter if the request is made at the time of order.

Operationally, the Kris scanner is a wonder. It sits there silently and does exactly what it was made to do–quickly, efficiently, and rhythmically. The receiver scans at the rate of 20 samples per second, so that each channel (there are seven of them) gets "visited" every 0.3 second. The scanning rate remains the same whether some channels are skipped (locked out) or not. Each of the seven channels has a numbered indicator lamp that glows during each "sample-taking" period. When a signal appears and the receiver locks on, the lamp for that channel stays on so the operator can identify the active channel.

I checked the unit out in the 73 Magazine office where the sophisticated test equipment complement consists of a volt-ohmmeter and a pair of pliers–so there was little in the way of measurements that could be done. But I did have a receiver of known sensitivity for comparison, and all indications were that the Kris performed in consonance with the manufacturer's specs; signals that quieted the known receiver by 20 dB did the same on the Kris scanner. Since the "control" receiver was rated for a sensitivity of 0.5 μV for the 20 dB quieting factor, it is safe to assume that Kris' specs (identical to those for the control receiver) are accurate.

With respect to bandwidth, it should be noted that the Kris is a "good" receiver–and, like any good receiver, it is reasonably selective. But a highly selective receiver can't have a broad bandwidth without some compromise. Thus, the Kris scanner should be tuned for the frequency in the center of its range. The performance tends to degrade gradually off either side of the center frequency of interest. Since the degradation is insignificant over a range of several megahertz, this little tidbit of information will be inapplicable to most users. But if you plan on monitoring the local repeaters as well as the police frequencies in the 155 MHz region, try to plan your channels so that the top frequency is no more than 8–10 MHz from the lowest frequency of interest. And even then you'll have to compromise the sensitivity on the low end if you want acceptable performance on the top. For the conventional repeater frequencies, however–between 146 and 148 MHz–you'll find no deterioration in performance over the whole range.

All things considered, I think the scanning receiver will find a home with the FM crowd. Even if you don't have a lot of active channels in your area, it's always nice to monitor the more popular frequencies for transient mobiles, DX, or blossoming FM activity. The scanner is really great . . . easy to get used to . . . easy to get dependent upon. But what I can't figure is why nobody has ever made a scanning transceiver?

TWO CONVERSIONS FOR THE MOTOROLA 41V

PART 1: AC POWER SUPPLY

Jim Romelfanger K9PKQ
117½ 4th Street
Baraboo WI 53913

This power supply was designed to provide the voltages necessary to operate the 41V Motorola mobile as a base station. The idea behind the supply was to make it possible to convert a unit for ac operation without removing any parts necessary for dc use. This adds considerably to the utility of the unit. An operator can use it at home on ac, but when he wishes, he can reinstall it as a mobile by the simple addition of a jumper plug.

The supply uses a common TV transformer in a full-wave circuit to provide a B+ potential of 325 to 350V, and a divider network for the low B+ stages of the rig. You may have to adjust the divider resistor values to come up with the exact values of low B+ called for.

The relays are supplied by a small filament transformer and a full-wave bridge rectifier. The diodes here can be most anything over a 500 mA rating and 100 PIV or better.

Please note that the diagram shows a supply for a 12V dc rig. If your rig is for 6V, either convert it for 12V or be sure to use a 6V relay supply transformer, and use only one 6V winding on the power transformer (the heaviest, of course).

With this conversion, control connections are made through the normally used 19-pin connector on the front panel. If the rig is a front-mount unit, you are really in business.

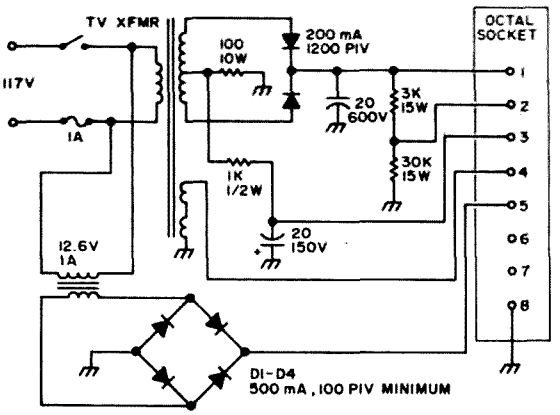

Fig. 1. Ac power supply for Motorola FMTRU-41V. (Original supply is shown in companion article.)

Step-by-step modification:

1. Remove RED lead from C10A and connect it to power socket pin 7.
2. Connect power socket pin 1 to C10A.
3. Connect power socket pin 2 to C9A.
4. Connect power socket pin 3 to terminal 10 on transmitter power supply strip.
5. Connect power socket pin 8 to ground.
6. Remove yellow lead from fuseholder and reconnect it to power connector pin 6.
7. Connect power socket pin 4 to fuse.
8. Remove relay lead from pin 2 of driver tube (2E26) and run to power socket pin 5. This step is for 12V units only.

Table I. Power plug connections.

Pin	Voltage	Current	Mode	Notes
1	350	150 mA	transmit	
2	200	55 mA	receive	
	150	50 mA	transmit	
3	-20		transmit	Bias
4	12.6 ac			6.3V ac in 6V equipment
5	12 dc			Relay supply
6	N/C			
7	N/C			
8	Gnd			

NOTE

If the unit being converted is a 6V model, change step 8 as follows: Remove the lead between E2-9 (transmitter supply tie strip) and K1-9/K1-10 (relay). Connect K1-9/K1-10 to power socket pin 5. Supply filament voltage to pin 6

The octal chassis connector plug is mounted on a small aluminum plate on the metal extension above the 19-pin control connector (top side of the power supply chassis).

Note that there is very little filtering in the ac supply. The capacitance in the rig has been found to be adequate to take care of ripple. It is possible, however, that the filters in the unit may have deteriorated and lost some of their ability to filter. In that case, replace 'em. Many units of this type have been subjected to considerable heat, which is rough on electrolytics.

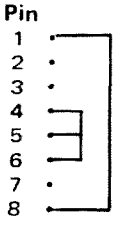

Fig. 2. DC jumper plug wiring.

The jump plug for dc operation can be wired up and then tied to the rig with lacing cord. Then it's there when you want it. Jumper wiring is shown in the shcematic.

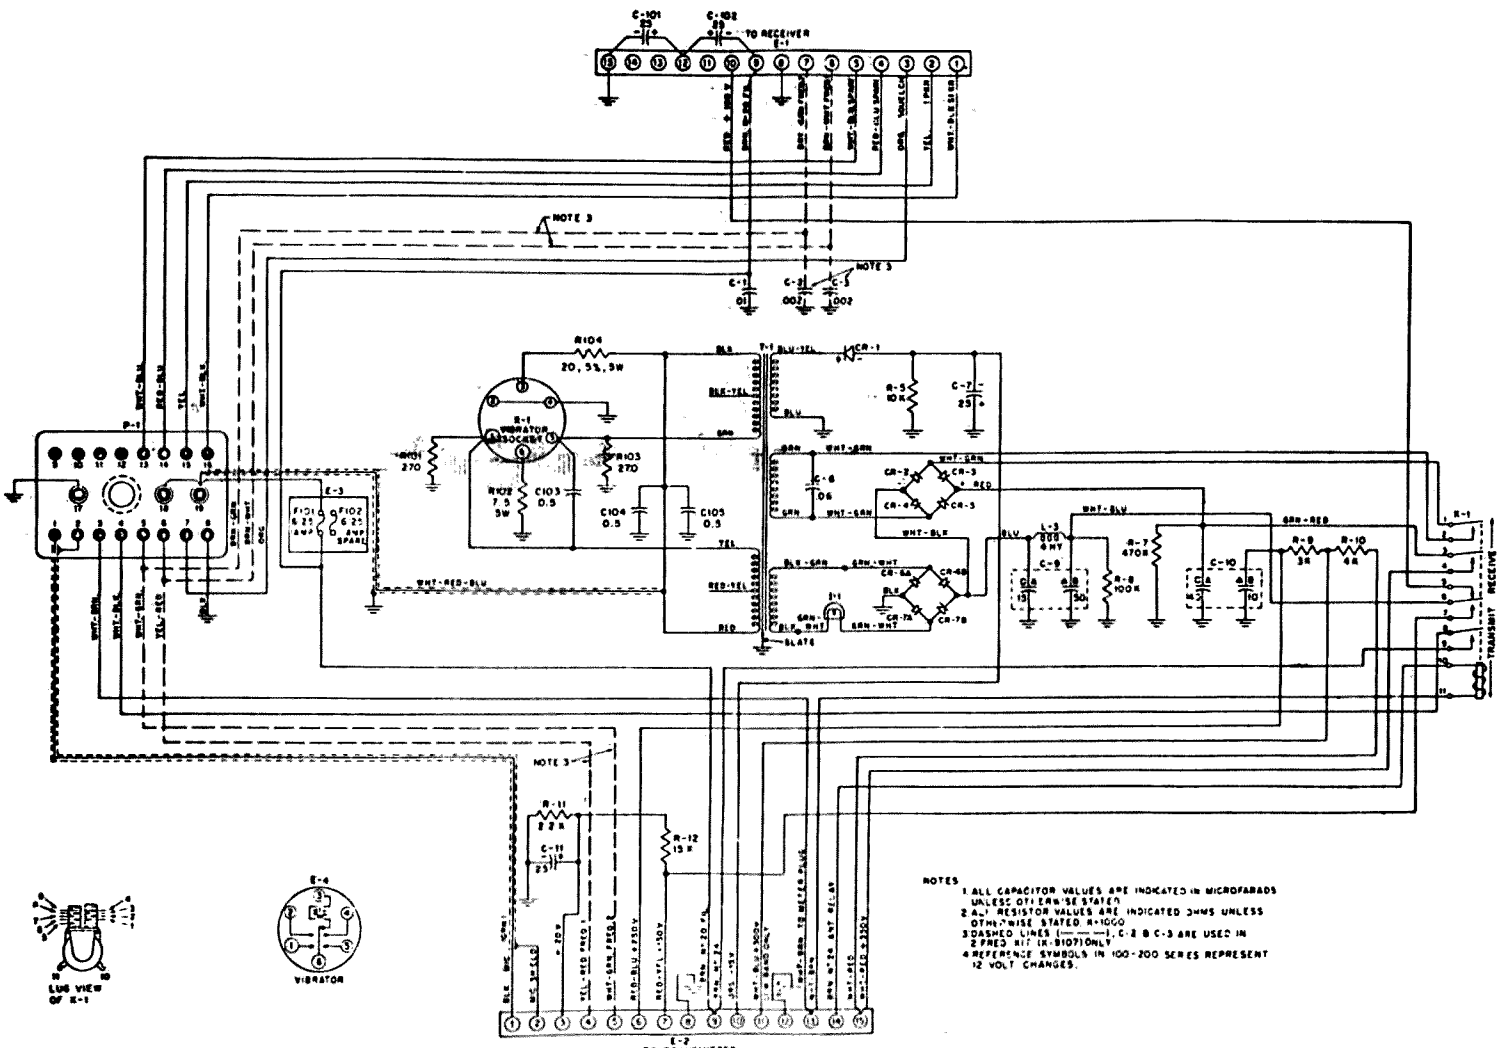
PART 2: 6 TO 12V FILAMENT CONVERSION

Donald L. Milbury W6YAN
Box 463
W. Covina CA

Setting up the 41V to operate on two meters is too simple to warrant a complete article on the subject. After a few preliminary value adjustments, the tuneup procedure is perfectly straightforward. This article deals primarily with changing a 6V unit to 12V; but, in the interest of completeness, here is the frequency conversion information:



1. Add 2-5 pF from pin 1 to pin 3 on L1, L2, L3, L4, and L5 of receiver.
2. Add 4 or 5 pF from pin 1 to pin 3 on L7, L7A, and L8 of receiver.

Crystal data:

Transmit – Motorola Type R09, 85°C oven. Specify operating frequency; Sentry will correlate.

Receive – Most common is Motorola Type R21 (85°C oven). Specify operating frequency; Sentry will correlate.

Sentry address is: Crystal Park, Chickasha OK 73018.

41V POWER SUPPLY AFTER MODIFICATION TO 12 VOLTS

6 to 12V Conversion Transmitter

a. Doubler driver (V106)
   (1) Disconnect and remove the jumper between pins 7 and 8.
   (2) Disconnect the brown-white lead from pin 2 and connect it to pin 7. This connects tubes V106 and V107 in series.

b. Tube V105: 3rd doubler (25–50 MHz) 2nd doubler (152–174 MHz)
   (1) Disconnect and remove the ground lead from pin 3.
   (2) Disconnect and remove the jumper between pins 2 and 3.
   (3) Connect a jumper between pin 2 and the center shield (gnd).
   (4) Disconnect the brown-white to pin 3. This connects tubes V101 and V105 in series.

c. Audio Amplifier (V108)
   (1) Disconnect and remove the ground lead from pin 9.
   (2) Remove the jumper between pin 9 and the center shield.
   (3) Connect a jumper between the center shield and ground.
   (4) At the V108 tube socket, disconnect the brown lead (running from tube V109) from pin 4 or pin 5, depending upon which is used, and connect it to pin 9. This connects tubes V108 and V109 in series.

d. Tubes V102 (modulator), V103 (buffer and 1st doubler), and V104 (2nd doubler – 25 to 50 MHz tripler – 152 to 174 MHz

   Replace the three 6AU6 tubes (V102, V103, and V104) with 12AU6 types.

e. Antenna Relay
   (1) Remove the three screws that hold the antenna relay cover to the chassis. Unsolder the relay cover from the shield around the rf section.
   (2) Remove the solid bus which connects the relay coil to ground.
   (3) Connect the brown-white lead between the relay coil lug, from which the ground bus was just removed, and pin 2 of tube 106.
   (4) Replace the antenna relay assembly on the chassis by means of the three screws. Resolder the relay cover to the rf shield. This connects the relay in series with the transmit-receive relay on the power supply chassis.

f. Crystal Socket (Single-Frequency Models)
   (1) Mount two 15Ω resistors near the crystal socket by using existing holes in the chassis. Place one lockwasher, one eyelet, and one fiber washer at each end of the resistor. Connect the resistors in parallel.
   (2) Disconnect and remove the ground connection from the crystal socket.
   (3) Connect one end of the paralleled 15Ω resistors to the crystal socket terminal from which the ground connection was just removed.
   (4) Connect the other end of the paralleled resistors to ground.

g. No. 2 Oscillator V201 (two-frequency models only)
   (1) Disconnect and remove the jumper between pins 2 and 3 of the V201 tube socket.
   (2) Connect a 39Ω resistor between pin 3 of tube V201 and the grounded lug on the crystal socket (X202). This connects the filament of tube V201 in series with the 39Ω resistor across the 12V source.

h. Crystal Assemblies (two-frequency models only)
   (1) Make a note of the frequency of each crystal and remove the two crystal assemblies from their sockets. The crystals must be removed from each 6V assembly and inserted in the new heater and base assembly as outlined in the following steps. Use care so that 6 and 12V assemblies are not mixed.
   (2) Remove the housing cover by releasing the ring clamp.
   (3) Remove crystal from the 6V base

(continued on page 93)

A CW MONITOR

How to get a 98¢ oscillator module to key on and off with your rf

J. A. Houser WB2GQY
23 Washington Street
Rensselear NY 12144

It seems that selfishness, next to greed, is the greatest incentive to invention – to want some device to accomplish some desire; and when such is not available, the selfish man will create it, if possible.

I found myself in this position with regard to a desire to be able to monitor my CW transmissions on any band – *without* touching the monitor other than to turn it on when required and shut it off when not, without any connections whatsoever to the transmitter, as I detest modifications of equipment.

After scanning handbooks and catalogs, I could find nothing like what I wanted, so I decided I would just have to build one. I felt this could not possibly be a complicated device. Live and learn!

The untunable, nonresonant quality I wanted appeared perhaps to be the most insurmountable obstacle. Transistors seemed to be the most feasible devices to use in view of the fact that self-power was also an objective.

Did you ever try to pick out a particular transistor for a particular application – with the thousands, nay, maybe tens of thousands of transistors to choose from? If you did, perhaps you might do as I did – use what you have! Somehow, you always seem to find something that will work.

But to get on with the project: Of necessity, you have to have an audio oscillator and a speaker. I saw a cheap audio oscillator module in the Lafayette catalog for 98 cents and I figured I couldn't make one for less, so I bought that along with a small steel-encased speaker with a universal bracket (see parts list). This module is designed to work with anything from 1.5 to 6V, but 3V is recommended. One of those battery holders which hold two size D flashlight cells side-by-side seemed ideal for the power. Everything was swell so far; it worked well, with two pieces of hookup wire for the key, as I didn't intend to key it anyhow. An instruction sheet came with the module showing hookup. The note is about 1 kHz with 3V applied.

Now the sticky part of the design started to erupt. You have to have something to switch the module on and off with the CW signal. Seemed like a power-type transistor should work, but how much power? What current does the module draw from 3V? Nothing like measuring it – here is the result:

V	mA	R (load)	W
1.5	19	75	0.030
3.0	32	93	0.096
4.5	38	119	0.18
6.0	45	133	0.27

So you will need a transistor that will handle 96 mW, and this eliminates any of the small audio output transistors such as

used in the little BC radio receivers, because most of them put out only about 20 mW. An audio power output transistor such as used in the auto radios will handle 100 to 200 mW, so it is ideal. Since I just happened to have one of these on hand, I hooked it up as in Fig. 1 to find out what control voltage I would need to fire it.

Now I had to decide whether to do a lot of research to determine whether all the parameters were correct or whether just to hook it up and see if it worked. I decided on the latter. I hooked it up per Fig. 1 and started with 1.5V between X and Y, then 3.0, then 4.5 and 6V. Finally, with 9V, it fired, and the audio oscillator switched on. Now I was almost certain I could not get 9V dc out of rf rectified from a small whip antenna to fire this directly, so I figured I would have to put another control switch (transistor) ahead of this one to control the 9V needed to switch it on. Perhaps I could pick one out that would take about 1.0 to 1.5V dc from rectified rf to switch it on and off – sort of a double switch, if you will.

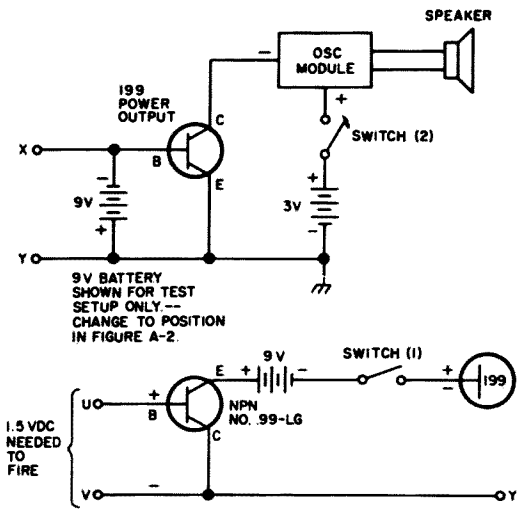


Fig. 1. Test setup. 9V battery is used in test only. Change to position shown in Fig. 1B.

I just happened to have another audio driver and output transistor such as used in miniature BC receivers on hand, so I tried this. It was an NPN type. I hooked it up ahead of the power transistor to see what voltage dc I would need to fire it, which would then fire the power transistor, which would then turn on (and off) the audio oscillator module. I found I needed 1.5V at the base to fire this one. It fired the power transistor, which turned on the audio oscillator, and I got a fine 1 kHz note. Everything so far was fine.

Now all I needed was 1.5V dc from rectified rf, and everything would be cooking. I tried a single IN34 diode hooked to a piece of hookup wire for an antenna, and the best dc I could get from this arrangement was about 0.3V.

Well, why not an rf voltage doubler? After all, these work at 60 Hz and are used in many receivers and some low-power transmitters. So I hooked up a voltage doubler as in Fig. 2.

Sure enough, up went the rectified dc voltage. In the 40 meter band it even went as high as 12.0V dc; and in the 80 meter band it was about 1.8 to 2.5V dc, which should be more than enough. However, in the 20, 15, and 10 meter bands, I could get only about 0.3 to 0.9V, which would not fire the first control transistor.

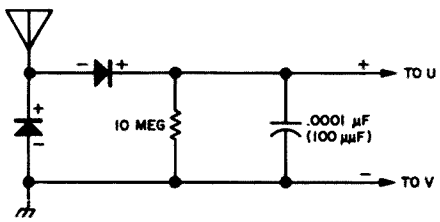

Fig. 2. Voltage doubler rf pickup. 1N34s.

I thought maybe I could improve the antenna pickup to acquire the additional voltage required. I tried all kinds of loops, from 1 turn to 100 turns, figuring the electromagnetic pickup might be predominant over the electrostatic pickup from a unipole antenna, only to find out that no loop at all would work. The pickup just has to be from a unipole! Then I tried a counterpoise along with the antenna, figuring I might end up with a pair of rabbit ears. Nothing except a single unipole would work. I had been working with GE IN34 AS type germanium diodes, so decided to try some surplus ones removed from old IBM computers. All seemed to work about the same,

A - next higher frequency may be useful
B - difficult circuit this period

and I could not get the rectified dc higher on the higher frequency bands. Next I minia-

Monitor can be set up simply on a piece of perforated board. It's a lot easier than a PC board.

turized the breadboard layout. Nothing changed, and now it was small enough to put into the speaker case on one side, with the code oscillator module on the other side, and the antenna coming out the top.

So I now have a nice little miniature CW monitor on 80 and 40, which are the two bands I work CW on most. Anyone who wants to use this on 20, 15, or 10 may, with a little more research and development, get it to work on the higher bands.

Here is the parts list with approximate prices:

- 2 diode rectifiers, GE 1N34AS or equivalent ($1.50)
- 1 pkg. (100) T-28 terminals, Laf. 19-8302 ($1.55)
- 1 P91 terminal inserter, Laf. 19-8306 ($.50)
- 1 2" x 4" PC Vector, phenolic punched board–for no. 28 terms. ($.25)
- 1 3" speaker and case, Laf. 44-5201 ($6.45)
- 1 9V battery holder–Keystone 173 ($.35)
- 1 Cordover solid state oscillator module, Model CPO-4, Laf. 19-1513 ($.98)
- 1 Workman TV transistor NPN, 99-L6, audio output ($1.00)
- 1 Workman TV transistor, power, WTV-199-140 ($1.50)
- 1 100 pF capacitor ($.15)
- 1 5 meg ¼W resistor ($.12)
- 1 old antenna rod from TV rabbit ears or old auto antenna
- 1 5/16" rubber grommet
- 1 9V transistor battery
- 2 1½V D flashlight batteries; hookup wire, solder, etc. as required
- 1 DPST slide switch ($.35)

The Logical Approach to Surplus Buying

Jim Kyle

All that's surplus is not military . . . or FM.

Take a look at the surplus ads in this issue—and you may be a bit surprised by what is turning up on the market these days.

For instance, a random sampling of a recent issue shows one ad featuring a "6,400 memory drum," faced by another which offers "brand new RTL integrated circuits." Elsewhere in the same issue we find "universal logic circuit cards," and a potpourri of "dual 4-input *nand* gate," "quad 2-input *nand* gate," and "J/K flip-flop master slave" IC chips. That's all a far cry from the decoherer, spark gap, and Alexanderson alternator—or even from the push-pull 304TL's or war-weary ART-13's which used to be the mainstay of the surplus market.

It's probably an insult to most of you to assume that you don't know that all these strange new items in surplus come not from military communications channels, but from the computer industry— and so it won't be assumed.

But the question just may remain open, as to what earthly (or spacely, either, for that matter) use such gadgets could be in ham radio. And the purpose of this parcel of prose is to attempt to provide a route toward finding some answers to that question.

Now that we have assumed that everybody knows these strange things come from the computer industry, we'll be a bit more specific and point out that it's the *digital* computer industry which provides most of the goodies. Analog computers are still with us, and will be for a long long time because for some purposes, they're better machines—but the big money, and the big market, is for digital computers, and Detroit has nothing on the computer sciences. After all, if you buy a new car you can expect it to

run for at least three years, and maybe even until it's paid for—but the average life of a large-scale computer system is more like two and a half years. By that time, the state of the art has advanced so far that your "brand-new" machine is obsolete.

This rapid obsolescence cycle is what's putting so much computer surplus onto the market now. While most hams are still a bit puzzled by the whole idea of integrated circuits (sort of like we were by transistors way back in 1959 and 1960), the computer people have moved through two whole "families" of IC designs and are now well into the third generation. The obsolete stuff has to go somewhere, and that's where the "surplus" comes from.

"Fine," you may be saying, "but I don't want to build a computer. What good is this stuff to me?"

Patience. It may turn out to be a gold mine for you. And it may not. Only you can decide that, but in the pages which follow we're going to try to give you enough information to let you make the decision, and to let you use these things for purposes their original designers never had in mind.

Logic Elements

Right here at the outset it would probably be a good idea to define some of the words and phrases used in the computer industry for these circuits, because the ads cited earlier reveal some lack of understanding—and when the sellers are mixed up, then the buyer who knows what the words mean has a chance to get even better bargains than usual.

Computer designers tend to think in terms of *logic elements*, which can best be thought of as little black boxes which do one and only one job. The most common types of logic elements are flip-flops, gates, and a third type variously called a buffer, a driver, an amplifier, or sometimes an inverter.

Flip-flops are logic elements which have at least one and sometimes as many as four input terminals, and usually two output terminals. The signals at the input terminals determine the "state" of the flip-flop, but once the state has been either "set" or "cleared," the input signals can be removed and the output terminals will continue to indicate the state without change. The major purpose of a flip-flop is to "remember" a transient signal level or condition; several flip-flops, of some special subtypes, are often connected in cascade one after the other to serve as a counting circuit.

Gates are logic elements which have two or more input terminals, and usually a single output terminal. The presence or absence of signals at the input terminals, and especially the combinations of signal levels simultaneously present at all input terminals, determine the signal at the output terminal. Gates have no memory capability; when the input signals change, the output signals change also.

The third class consists of logic elements which normally have only one input terminal and one output terminal. The names buffer, driver, and amplifier mean the same in the computer world as they do in ham radio. This logic element provides isolation between more active stages in a design, and also helps provide driving power (because digital-circuit input terminals represent fairly heavy loads upon their driving circuits). The inverter is a special subclass of this type of circuit, which produces an output signal of opposite value to its input signal.

We'll go into these types of logic elements in more detail a little later, but before we do there are several other terms which are not exactly everyday phrases in amateur radio—which are, still, important in understanding how these circuits work.

Digital circuits are, almost without exception, designed to operate with "binary" signals. A binary signal is one which can take on only one of two possible values. For instance, it may be a +2V level, or a ØV level, with respect to ground. In practice, the actual circuit will be built to interpret any voltage above some specific value as being the higher of the two levels, and any below that value as being the lower. This voltage level, which separates the *high* from the *low* binary signal value is known as the *threshold* of the circuit, and the exact voltage values which are the two values of the binary signal are known as the *logic levels*. Often, one of the logic levels is zero volts, and then only the other logic level is specified.

We mentioned a bit earlier that digital

circuit input terminals represent quite a load to their driving circuits. When we get to the actual schematics, you'll see why. Because of this, digital circuits are rated for *fan-in* and *fan-out*. The units used for rating fan-in and fan-out are usually arbitrary. One type of gate, for instance, might represent a 2-unit load and be rated for a fan-in of 7 and a fan-out of 12.

This would mean that such a gate could accept at any one of its inputs, then, connections to three identical gates, and could drive from its own output terminal six other gates.

If more than 6 gates need to be driven to make the circuit do what the designer intended, he would have to add a buffer as one of the loads on this gate. The buffer might represent a 3-unit load, and that would leave only 9 units of fan-out available so that only 4 other gates and the buffer could be connected.

The fan-in and fan-out ratings are meaningless unless you know the number of units of load represented by each logic element you want to include in a circuit, but they still give you an idea of the relative power output of different elements in the same family. The higher the fan-out rating, the more power is available at the output terminal.

The Logic of Switches

Before we can make much practical use of the digital circuits available in surplus, we need to know how the circuits work. And to do that, we must know a bit about electronic logic circuits. Fortunately, it's not very complicated. What makes a computer circuit so complex is not the individual circuits– each circuit is about as complicated as a diode detector, and far less difficult to understand than an audio amplifier – but the vast numbers of them involved, and the hundreds of feet of interconnecting wiring hooking them all together.

You can't get much less complicated than a simple switch – but that's just what the basic digital logic circuit amounts to. If the switch arm is in one position, current flows one way; if the switch arm is in the other position, the current flows to the other terminal. The "live" pole indicates the position of the switch –but we usually think of it in a different way, and believe that the position of the switch tells us which way the current's flowing.

This is fine if it's *us* who has to do the remembering, but in a computer it's the circuit which must remember something. And it may be overstating things to point out that the "up" or "down" position of the switch handle *does* remember for us what we did there last. This small fact is never fully appreciated until you work with equipment which uses "alternate action" switches which you push once to turn on, again to turn off, and after they're pushed you can't tell by looking whether they are on or off.

Let's take that SPDT switch and connect a couple of them to form a logic gate. **Figure 1** shows the circuit. Electricians among the readers may recognize this as the "three-way switch" circuit for turning a light either on or off from either of two locations, but it's a logic gate circuit as well, because the output signal (the fact that the light is one, or off) depends upon both input signals (the positions of each switch individually). If switch A is up and switch B is down, or vice versa, the lamp is off. If both switches are up, or both down, the lamp is on.

In logic, a *truth table* is often used to describe the actions of any logic element. **Figure 2** is a truth table describing the circuit of **Fig. 1**. The important thing to note here is that every possible one of the switch positions is included in the table, and the output condition for each of these possible input conditions is also included.

The truth table in **Fig. 2** uses words to describe the input and output conditions. Truth tables used to describe the functions of various logic circuits usually use either the initials **T** and **F**, for *true* and *false*, or, more often, the numerals **1** and **0**, to describe the two states of the signal level.

Remember that these circuits operate only with binary signals. If we name one logic level **1** and the other logic level **0**, we can then relate the actual voltages at the input and output terminals of any circuit to the **1** and **0** entries in the truth table for that circuit, and the truth table will tell us what output the circuit will produce for any possible combination of input signals.

To illustrate the point, **Fig. 3** is a redrawn

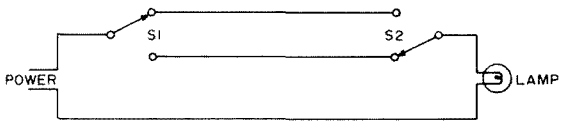

Fig. 1. This simple circuit, known to electricians as a three-way switch, for controlling a light from two separate locations, is also a rather exotic digital logic circuit. No gate used in digital logic is any more complex than this circuit, though it may have more control points.

Switch Positions		Lamp
S1	S2	
down	down	on
down	up	off
up	down	off
up	up	on

Fig. 2. Truth table describes all possible conditions of a three-way switch circuit. Left two columns show switch positions and right column shows lamp condition which results from each combination of switch positions. Systematic tabulation of switch positions insures that all possible combinations are included; positions for S2 alternate from down to up to down to up, changing at each line, while positions for S1 change only when a position of S2 is repeated. If the circuit had three switches, 8 lines would be necessary to describe all

version of **Fig. 1** with the switch positions labeled as **1** and **0**, and also includes the truth table in **1** and **0** terms. In this table, an output of **1** means the light is on, and a **0** output means the light is off.

If we think only of two-input gates, we could design circuits to fulfill any of 16 truth tables. **Figure 4** shows all 16 of these possible truth tables for two-input gate logic circuits. In practice, only a few of these 16 are used to any degree. The most common gate circuits found in surplus are those known as *nand* and *nor* gates. **Figure 5** shows the truth table of both the *nand* and the *nor*. The three-way switch circuit of **Figs. 1** through **3** is known in logic as an *exclusive or* circuit; you're not likely to find one of these in surplus, because when a logic designer needs an *exclusive or* gate he usually builds it up from several *nand* or *nor* circuits.

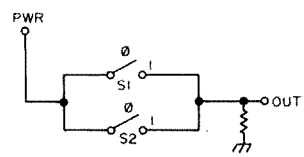

Fig. 7. Schematic and truth table for switch version of **or** *gate. Since switches are in parallel, either switch being in* **1** *position produces a* **1** *output, and a* **Ø** *output occurs only when both switches are open.*

(that is, in the dim dark ages of some three to five years ago), the most common logic circuits were the *and* and the *or* arrangements. **Figure 6** shows an arrangement of switches which produces the *and* function, together with its truth table, while **Fig. 7** shows switches to create an *or* gate.

The names are almost obvious from the circuits. In the *and*, both (or all, if there are more than two) inputs must be at the **1** logic level in order to produce a **1** output. If any input is at **Ø** level, the output is **Ø**. In the *or*, either input **1** or input 2, or input 3, or . . . being at the **1** level is enough to produce a **1** output, and a **Ø** output results only if all the inputs are at **Ø**.

Figure 8 shows both the *and* and the *or* circuits redrawn to substitute transistors for the switches. Notice that the transistor is virtually an exact substitute for the switch—but a transistor can switch from on to off in a microsecond or less, while actual switches take considerably longer.

Let's move back to actual switches one more time, though, to examine the *nor* circuit. This name is a contraction of *not or*, because, as you can see by comparing truth tables, the only difference between an *or*

and a *nor* is that the output of a *nor* is **1** under the input conditions which would make an *or's* output **0**, and vice versa.

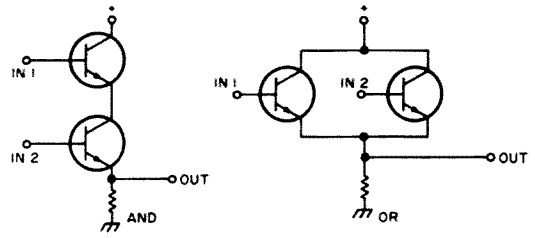

Fig. 8. Substituting transistors for the switches in Figs. 6 and 7 produces these circuits, which are workable transistor-logic versions of the **and** *and* **or** *gates. These exact circuits are seldom used in practice because the input logic levels must swing over a greater range than the output levels. Before IC usage became common, most logic circuits used diode gating; with the advent of ICs, the* **nor** *and* **nand** *circuits became the preferred versions.*

The circuit of **Fig. 9**, which is simple enough, produces a *nor* gate. If either switch is closed (the **1** position), the output signal is shorted to ground to become **0** level. If both switches are open (the **0** positions), the output rises to the level of the supply voltage and becomes a logic level of **1**.

Just by switching the names of the logic levels and switch positions, so that closed switches mean logic level **0** and ground voltage is an output level **1**, we can change this same circuit to a *nand*. If you disbelieve this apparent contradiction, check it out against the truth table. Sketch the circuit four times, setting the switches to each of their four possible combinations, and check the output voltage by name. It will follow the *nand* truth table when closed switches indicate **0** and ground output indicates **1**,

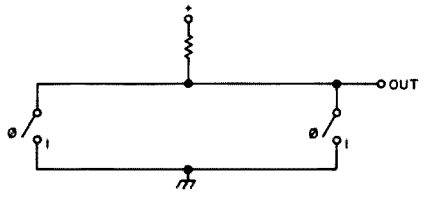

Fig. 9. Two switches and a resistor suffice to form a **nor** *circuit, which as you can see by comparison with Fig. 7 is simply an "upside down* **or**." *Turning the circuit upside down inverts the output, making it "***not or**," *which was contracted by busy engineers to* **nor**. *With switches this circuit offers no advantages over the plain* **or**, *but when transistors are substituted, a major advantage appears (Fig. 10).*

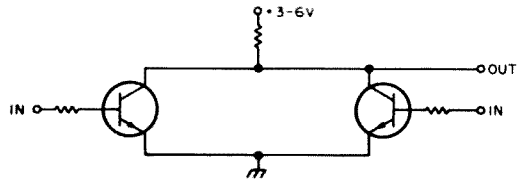

Fig. 10. Schematic of transistorized nor *gate obtained by replacing switches of Fig. 9 with type 2N706 transistors, and adding series resistors to limit base current. This is the circuit used for each gate element in Fairchild Micrologic type 914 ICs, and any RTL* nor *gate will have similar schematic. Each input requires its own transistor, with all collectors connected together. When any transistor is on, output is at ground level; output is at supply level only when all transistors are off.*

and will follow the *nor* truth table if the closed switches indicate **1** and ground output is **0**.

In actual digital logic circuits, the usual difference is that one circuit uses NPN transistors and positive supply voltages, while the other uses PNPs and negative supplies. Sometimes, designers actually do use the trick of changing logic levels in mid-circuit, so that physically identical circuits may be *nand*s here and *nor*s there, with no way to tell the difference.

But we're a bit ahead of ourselves, because we haven't converted the switch-operated circuit of **Fig. 9** into its transistor equivalent yet. **Figure 10** does so —and takes us one step further.

In **Fig. 10**, a positive or **1** voltage applied to either base resistor will turn that transistor on, which is the same as closing the switch. The output will drop to **0**. You can build the circuit of **Fig. 10** using 2N706 transistors, or you can buy it in surplus as a Fairchild Micrologic type 914 integrated circuit. If you buy a 914, you'll actually get a pair of these circuits, completely independent of each other except for the power and ground connections. The 915 is the same except that it has three transistors per logic element instead of two, which makes it a dual 3-input gate (the 914 is a dual 2-input).

Some similar circuits known as quad 2-input gates simply have four independent 2-input circuits similar to **Fig. 10** inside.

You may run into circuits called "quad 3-input gate extenders" or words similar to this. The key word in this is *extender*. Beware of them for most purposes, because

they do not include the load resistor or power supply connection. Their purpose is to be connected across the output of some other gate to provide additional inputs. The gate extender does come in handy at times, though, should you want to use some value of collector resistor other than the 640Ω which is typical of a 914 or 903.

Flip-flops

In the sometimes illogical world of logic circuits, a flip-flop isn't always. You may meet R-S flip-flops, J-K flip-flops, type D flip-flops, and delay flip-flops. You might even meet a British import here and there which isn't a flip-flop at all but bears the name of one.

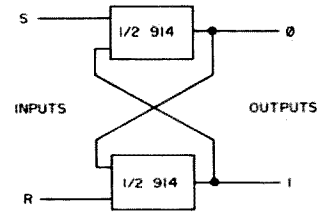

Fig. 11. By cross-coupling two halves of a type 914 IC, a type R–S flip-flop can be constructed. Two inputs for each gate are at left side of box representing gate element, and output is at right. Application of **1** *level to either the* **S** *or* **R** *input makes corresponding gate output a* **Ø**, *and if other input is also* **Ø**, *then the opposite gate's output must be* **1**. *This* **1** *feeds back to original gate to maintain a* **1** *input, and holds output conditions constant until flip-flop is switched to opposite state by applying a* **1** *to the other input terminal.*

The circuit most people think of when they hear the name flip-flop (if they think of a circuit at all) is the counting flip-flop which flips to one of its two states when a pulse arrives, and flops back to the opposite state when another pulse comes in. This one is more accurately called a trigger, or type T flip-flop –but you won't find it in surplus.

In computers, another kind of flip-flop, known as the R–S flip-flop, is often found. This one has two input terminals, and two output terminals. A 1 applied to the **S** input causes a 1 to appear at the output terminal labeled 1, and a **Ø** level to appear at the **Ø** output terminal. Both output signals remain even if the input 1 is removed.

Applying a 1 input to the R input terminal reverses the state of the flip-flop. The level at the 1 output becomes **Ø**, and the level at the **Ø** output becomes 1.

The R and the S at the inputs stand for *reset* and *set*. Some designers use **S** and **C** instead of **S** and R, to mean *set* and *clear* and thus avoid confusion between the act of resetting or clearing, and the act of re-setting or setting again.

An R–S flip-flop cannot count as does the type T; it merely remembers what the most recent signals applied to its inputs were. You won't find many R–S flip-flops in surplus either, but if you want one you can build it easily by connecting the two halves of a type 914 dual *nor* gate as shown in **Fig. 11**. A 1 applied to terminal **S** causes the output of that half of the 914 to drop to **Ø**, and this makes both the inputs to the other half **Ø**. With both inputs at **Ø**, this other half produces a 1 output at the 1 terminal. The 1 output is cross-coupled back to the other input of the first half, to hold conditions in case the 1 at terminal **S** is removed. The *reset* or *clear* condition works the same way, but the roles of the two halves are reversed.

The reason that you won't find either type T or R–S flip-flops in surplus is because a single integrated circuit was developed which can serve either purpose, as well as several additional ones. It is known as the J–K flip-flop. The name comes from IBM names for some of the signal wiring in its computers.

Like the R–S flip-flop, the J–K has two input terminals and two output terminals. However, in addition to these two pairs of terminals, the J–K always has a fifth terminal known as the *trigger* terminal, and often has either one or two additional terminals known as *unconditional set* and *unconditional clear*. The block diagram symbol for a complete J–K flip-flop, as set forth by military standards, appears as **Fig. 12**, and in this article we'll use the labels shown in **Fig. 12**. These labels are not actually as standardized as all that, though, and you may find authors using other words to refer to the same terminals.

In particular, any IBM literature you may happen to come across will refer to the **S** terminal as the J terminal, the T terminal as the **Q** terminal, and the **C** input as the K terminal. IBM uses the symbol **Q** for clock-

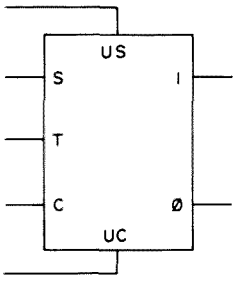

Fig. 12. Military standard symbol for J–K flip-flop, as set forth in MIL-STD-806B. Meanings of letters are explained in text.

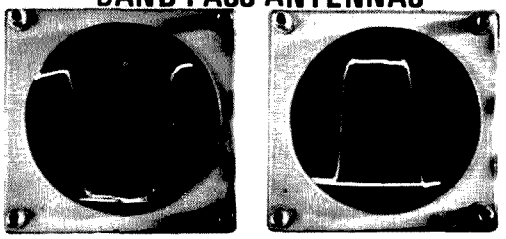
pulse signals, while **J** and **K** are names for logic level lines to the giant of the industry.

But the military has standardized on other names: **S** for *set*, **T** for *trigger*, **C** is for *clear*, **US** for *unconditional set*, **UC** for *unconditional clear*, and **1** and **Ø** are the outputs.

The J–K flip-flop is a bit difficult to describe by a truth table, since what happens at its outputs depends on the levels present at the **S** and **C** inputs *at the instant* of a pulse transition at the T input. We'll describe action of the Fairchild Micrologic 923 series, which is typical of J–K flip-flop action.



The 923 has six terminals; **S, C, 1, Ø, T,** and **US**. The **UC** terminal is omitted. If a positive logic level is applied to the **US** terminal, the **1** output terminal will go to ground level and the **Ø** output terminal will rise to nearly the dc supply voltage (which should not exceed 5V). This action occurs regardless of the conditions at the **S, C,** and **T** terminals, and is why the **U** in **US** stands for *un*conditional. This terminal is used for setting the flip-flop to a known condition when equipment is turned on, or whenever you want to clear it.

For the **S, C,** and **T** terminals to have any effect, the **US** terminal must be at ground level, ØV.

Under this condition, the levels at the output terminals will depend upon the levels present at the **S** and **C** terminals at the instant the voltage at **T** drops from positive to ground, and also (in some cases) upon the previous condition of the flip-flop.

If both the **S** and the **C** terminals are at high voltage, the negative-going transition at **T** will have no effect; the state of the flip-flop will remain unchanged.

NEW! HELP FOR HAMS
HANDBOOK OF LIGHTNING PROTECTION!!! Just published, written by a Registered Engineer for Hams, CB'ers, TV antenna installers and Commercial maintenance and installation personnel. Did you know that an arrester and #8 ground wire going to a 10 foot ground rod offers you practically no protection on a direct hit? You CAN protect against direct hit damage by using techniques in this new handbook. Tells you how in 1-2-3 fashion to gain complete protection from direct hits, using little different except technique! In lightning grounding it's all in HOW, not HOW MUCH you do.
NEW NEW FIRE-RING COAX LIGHTNING ARRESTOR just developed from research on what it takes to withstand direct hits repeatedly and survive. Permanent gap setting, no change, machined-in gap set for 4000 PEP, 50 OHM cable VSWR 4 or less. Built into PL-259 Plug.
QUIT QUAKING WITH FEAR EVERY TIME A STORM GOES OVER YOU! Get both HANDBOOK and 1 FIRE-RING ARRESTOR ONLY $2.95 ppd in USA; handbooks separately, $1.00; arrestors separately $2.50 each ppd S.A.S.E. for tech data sheets. You owe it to yourself & family to find out the truth! You may be sitting in a death trap if you used electrical power code grounding techniques in an attempt to protect yourself from lightning damage. Send direct to
DUSINA ENTERPRISES
571 Orange Ave. W., Melbourne, Fla. 32901.

If S is at high voltage while C is at ground when the voltage at T drops from high to low, then the Ø output terminal will go to ground and the 1 output will climb to the positive level. That is, the 1 output will mirror the level at the S input, and the Ø output will follow the C input.

If S is at ground and C is high at the transition, the reverse occurs; Ø goes high while 1 goes to ground.

If *both* S and C are at ground when the transition occurs, the flip-flop will reverse its state. If 1 was high before the transition, it will be low afterward and Ø will be high. If 1 was low before, it will be high afterward while Ø will be low. This is the counting action of the type T flip-flop; all that's necessary, then, to turn a J–K into a counting or type T unit, is to strap both the S and the C inputs to ground.

We aren't showing you a schematic of this unit, because it's almost unbelievable. The type 923 comes in a TO-5 can or epoxy blob, the same size as most entertainment transistors; the circuit contains 15 transistors and a rather large number of resistors as well. In addition, the way in which the transistors are used to obtain desired circuit action leads directly to mass confusion upon quick study of the schematic. Some of the connections appear impossible; the designers made use of, among other things, differences in switching speed between two almost identical transistors side by side on the microscopic chip, to obtain the action of a capacitor!

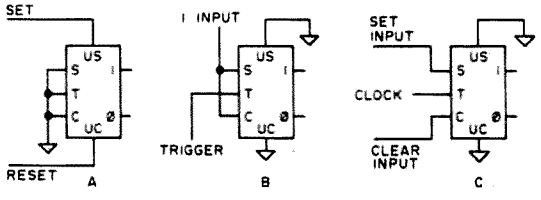

Fig. 13. Hookups for using J–K flip-flop as (A) type R–S flip-flop, (B) type T (trigger, or counting) flip-flop, and (C) delay flip-flop. Hookup A acts just like circuit shown in Fig. 11; outputs retain conditions set in by signals on set or reset lines. Circuit B reverses output conditions with each pulse applied to trigger input. Circuit C is slightly more complex. Conditions at set and clear inputs when clock pulse occurs are reproduced at outputs, until next clock pulse occurs.

Figure 13 shows the connections for using a J–K flip-flop as (a) an R–S flip-flop, (b) a trigger or counting unit, and (c) a delay flip-flop. The delay unit repeats at its output the conditions which existed at its inputs one trigger pulse time ago; it sometimes has a use in construction of electronic keys, and is the basis of such computer subassemblies as ring counters and shift registers. the situation is similar to that at the cutoff

What Have You Got?

Assuming that by now you've become sold on the whole idea and sent off for a package of ICs, you probably are in somewhat of a quandary attempting to find out just what you have on hand. Many of the surplus IC units have no identification markings which make any sense.

This comes about because most of the units available (other than those purchased directly from factory distributors) come from industrial surplus, and any identification marks on them are probably the part numbers assigned by the manufacturer who intended to use them, rather than being the type numbers put on by the semiconductor plant which made them in the first place.

Most ICs come in one of two distinct package styles. One is the multilead TO-5 can or epoxy configuration; the Fairchild 914 and 923 are good examples of these. The other is the DIP (for *dual in-line package*) which may have a varying number of connections. This is a small *flatpack* with the connections coming out on the two long sides. Many of them have 14 connections (including power and ground), with 7 coming out on each side.

If you're extremely lucky, the surplus house you bought your units from will have furnished you with a base diagram so you know which pin is which. Otherwise, there's some tedious detective work in store. It's not impossible, though.

It helps, in case you're having to figure it all out with no help from the dealer, to know whether the unit in hand is a flip-flop, a buffer, or a gate. It's also nice to know how many independent units are in the same package, because then you can get some idea of how many pins to test. But you can do without these aids.

The first thing necessary is to connect

power to the unit. Low voltage, with a current-limiting resistor of at least 1000Ω per volt of supply voltage is safest. A couple of D cells are ideal, with a 2.2 kΩ series resistor. This will give you 3V at just under 1 mA – enough to check out most circuits and not enough to harm very many. If you know which pins are power and ground, just connect them. If not, pick any pin at random as the ground and try each of the others, in turn, as the hot side. If you can't get any readings in subsequent tests which make sense, move to another pin with the hot side of the power source; after going all the way around, move to another pin and try again.

Sometimes it's handy to have a milliammeter in series with the power source. If you get nearly a 1 mA of current flowing, the circuit must be full on in the IC, and you probably have your power source connected to a pair of input terminals, or to an output terminal with reversed polarity.

With a 14-pin DIP unit, you might have to run through the whole series of identification tests 196 times to come out with an identification –but the odds favor getting one sooner. From this, you can see just how much it does help to know where the power goes in the first place.

With power connected, measure the voltage from each of the other leads to ground. Some of the leads will undoubtedly measure nearly full supply voltage, and others will measure at ground. Leave the meter on one of those showing high, and short each of those showing ground, in turn, to the supply (at the IC side of the current-limiting resistor; it won't hurt to use another 2.2 kΩ resistor in series, if you're the cautious type). If any of these causes output voltage to drop to ground, make a note of the pins involved.

After all the no-voltage pins have been tried, try shorting the other high-voltage pins to ground, one at a time. If one of them brings the meter to zero, make a note of it.

When all of the pins which originally showed voltage have been checked out, move the meter to one of the pins which showed zero volts originally, and try the same thing again with all the other pins, noting any which cause voltage to appear, and what was done to each. Go all the way around with this series of tests, too.

By now, your notes will present a complete truth table for the unknown unit. The next step is to study it carefully to see if it falls into any of the patterns of Fig. 4. Any combinations of pins which produce such a pattern probably form an independent gate element within the IC; they should be checked out carefully by connecting the meter to the apparent output pin, and

applying the appropriate high or low levels to all the input pins at the same time.

A Few Helpful Hints. Most of the gate functions cannot be detected by single-input-pin tests such as those described here. If you find apparent "inverter" action from several input pins to the same output pin, the apparent output pin is probably the actual output pin of a gate element of some sort, and the apparent input pins are probably the actual gate element input pins. Try combinations of high and low levels at all the input pins simultaneously while reading level at the output pin, to find any similarities to the truth tables of **Figs. 4** and **5**.

If any of the single-input-pin tests cause an output voltage level to switch and stay in the opposite condition, you probably have a flip-flop; gates do not stay in alternate states, but hold their output levels only so long as inputs are supplied, while flip-flops "remember" inputs and do not need to keep them applied to have a changed output. If you find a suspected flip-flop, try multiple-pin tests by connecting all pins except the one you're testing and the output pin you're measuring from, to ground. When you find the single pin which causes output to reverse when the contact is either made or broken, under these conditions, you know the T input terminal and one of the two output terminals. From there, it's trial and error to find the rest of the connections.

After a little experience with this type of detective work, you'll probably develop a feel for it which may defy explanation. If you want to develop the feel without all the trial-and-error headaches, invest in a few units which come with connection diagrams (if you can find such), and practice with them.

Using Logic Elements Illogically.

While it's possible that you may become so fascinated with the possibilities inherent in logic circuitry, as such, and forget all about radio, that's not very likely. It's much more probable that you're only messing with all this Boole (to steal a good pun) because you want to make use of the ICs in some circuit that has nothing to do with electrical logic machines.

In that case, you'll probably welcome this portion of our discourse, because the rest of this article is devoted to some typical ways of using digital IC elements in ham radio.

The most versatile of the ICs for such uses is probably the 2-input *nor* or *nand* gate, of which the 914 is typical. A glance back at the schematic of this gate, **Fig. 10**, will show the resemblance between the *nor* gate and a *long-tailed-pair* differential amplifier circuit. All that you have to do to turn a 2-input *nor* or *nand* into a long-tailed-pair is to add the "tail," a resistor, between the IC's ground terminal and the actual circuit ground. The resistor value is not particularly critical; anything from 47Ω to 1 kΩ might do it, depending upon the signal levels involved and so forth.

You may also find it necessary to provide some forward bias to each of the two bases, by connecting a voltage divider to each of the input terminals. The complete circuit is shown in **Fig. 14**, but parts values must be determined by experimenting for each application. This circuit has been used as a mike preamp, and might also have other uses. High-frequency response is not particularly good, because the series resistors inside the IC (see **Fig. 10**) act with the junction capacitance to form a lowpass filter.

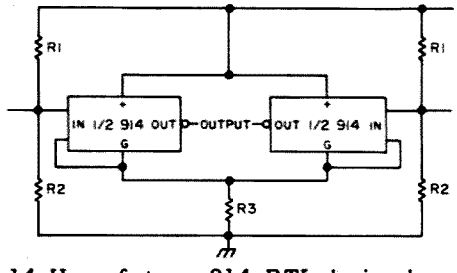

Fig. 14. Use of type 914 RTL logic element as differential amplifier is shown here. Values for R1, R2, and R3 must be determined by trial and error, but one such application has successfully used 1.8 kΩ at R1, 1.3 kΩ at R2, and 330Ω at R3. These values may be used as starting points. Output is taken directly from output pins of IC.

We already saw, in **Fig. 11**, how to cross-connect one of these gates into an R–S flip-flop, otherwise known as a *bistable multivibrator*. If we simply duplicate that hook-up, but put one capacitor and appropriate resistors in place of one of the direct wires, as in **Fig. 15**, we have a *one-shot* or *monostable multivibrator* which performs nicely as the frequency divider in a frequency standard. The frequency adjustment depends

upon both the capacitor size and the resistor values. Vary the capacitor until you're in the right ball park, and then use the resistance as a "trim" adjustment.

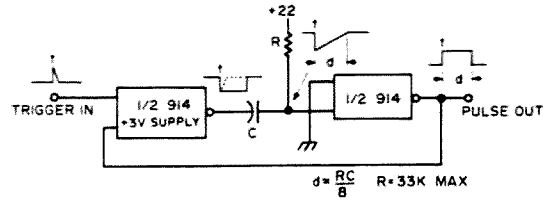

Fig. 15. One-shot circuit is easily built from 914 IC by adding single capacitor and external resistor. If 3V supply is used for IC, and 22V supply to drive external timing resistor, duration of output pulse will be almost exactly 1/8 the RC time constant, with R in ohms and C in farads. Maximum resistance usable for R is 33 kΩ to permit turn-on current to flow. Capacitance C, however, may be any value desired to achieve required output pulsewidth.

By substituting a crystal for the other cross connection, as **Fig. 16** shows, we can turn the dual *nor* gate into a crystal controlled oscillator with a high-harmonic waveform. It makes a fine frequency standard, especially if one or two dividers similar to the **Fig. 15** circuit are added.

If you want a free-running oscillator, you can get it by using capacitors on both sides. The circuit is just like **Fig. 16** except that another capacitor replaces the crystal. Frequency will depend upon values of both capacitors, and both sets of resistors.

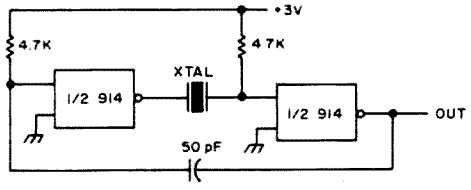

Fig. 16. Minor modifications to one-shot circuit, including substitution of a crystal for the timing capacitor and insertion of a capacitor in the dc feedback loop, turn it into a crystal-controlled oscillator which may be used for a frequency standard. Output is rich in harmonics, and this circuit is not recommended for transmitter use for that reason.

The *synchronous detection* technique for reception of AM, FM, and DSB signals has long been of interest to many of us, but too many transistors or tubes have been necessary in most circuits for synchronous or phase-locked detectors. Surplus ICs may, at long last, make phase-locking practical for ham receivers. (See W2EUP's frequency synthesizer description in 73, February 1970.) **Figure 17** shows a voltage-controlled oscillator (VCO) designed several years ago by a Motorola engineer using the Motorola MECL dual *nor* gate. Frequency varies over a 10-to-1 range as control voltage is varied from 1–7V. Both capacitors are the same value, and they control center frequency. Minimum value is about 110 pF, which provides a center frequency of about 2 MHz; maximum is 100 μF, which provides a center frequency of about 3 Hz (lowest frequencies with these two values are 750 kHz and 0.5 Hz respectively). For a 455 kHz i-f strip, 470 pF values would be about right.

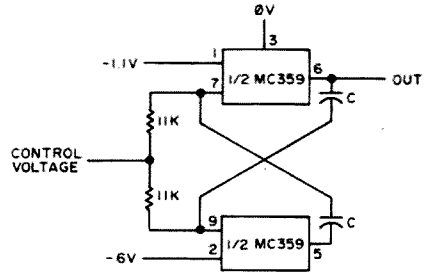

Fig. 17. Voltage-controlled oscillator can be varied over nearly 10-to-1 frequency range simply by varying control voltage. This circuit may be used as part of phase-locked detector.

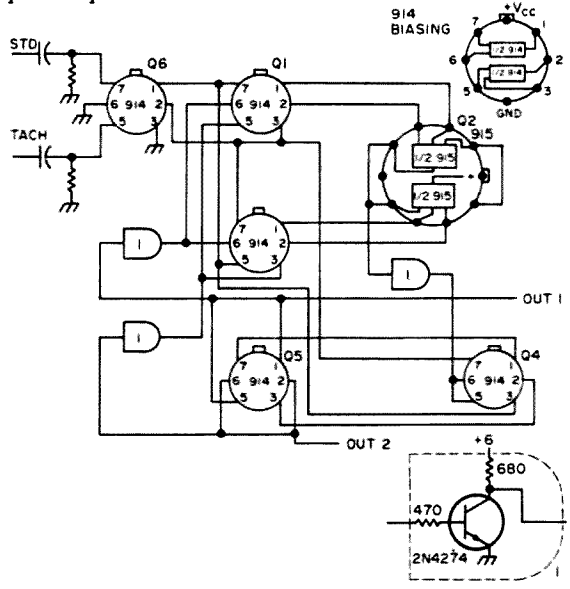

Fig. 18. This rather complex arrangement of ICs is a frequency comparator and phase detector. The unknown frequency is fed into the TACH input and the standard to which it is to be compared goes to the STD input. Output level indicates whether TACH is higher or lower in frequency than STD. OUT 1 and OUT 2 are of opposite polarity. Type 915 IC (Q2) is same as 914 but has 3-input gates rather than 2-input elements.

Figure 18 shows the frequency comparator or phase discriminator which goes with the VCO to provide half of a synchronous detector. This circuit was developed at Fairchild, and is not necessarily directly compatible with the VCO, but it should be possible to blend them together with a little trial and error.

The circuit of Fig. 18 accepts input signals at two connectors, labeled *REFERENCE* and *SIGNAL* in the drawing. It produces a single dc output. If the *SIGNAL* frequency is lower than that of the *REFERENCE*, the dc output level will be low. If the *SIGNAL* frequency is above the *REFERENCE*, the dc output level will be high. If both *SIGNAL* and *REFERENCE* are at the same frequency, the dc output level will be between the low and high levels, and will be determined by the phase relation between the input signals.

Unlike phase discriminators which make use of tuned circuits, this one has no humps in its response curve. The output will follow phase variations of the input faithfully, and can be filtered and used to drive the VCO in the classic phase-lock detector arrangement.

A somewhat less complex circuit which has nothing to do with radio but which may be of interest to the sports-car fanatics among us is in Fig. 19. This is a combination tachometer and dwellmeter, built around a single quad dual-input *nor* (Motorola MC724P). The gates at terminals 1-2-3 and 12-13-14 form a one-shot flip-flop timed by the 0.5 μF capacitor and 20 kΩ resistor. The gate at 5-6-7 is used simply as a driver, and the remaining gate (8-9-10) is the meter driver. Power is furnished by a pair of dry cells. In switch position 1, power is off. In position 2, the circuit acts as a tach, and resistor R1 should be adjusted to produce a 900 rpm reading when 60 Hz voltage is fed in. In position 3, it's a dwellmeter, and R2 should be set so that full-scale reading on the meter is obtained with the input terminals shorted. This will be 45 degrees of dwell for an eight-cylinder vehicle, 60 degrees for a six, and 90 degrees for a four. The meter can also be read as indicating percentage of time that points are closed, but most specs for tuneup give dwell readings in degrees.

This is, of course, only a sampling of the various uses which you can make of digital ICs. A little experimentation will probably result in several new ways – and now that they're in surplus, they're cheap enough to permit such experimentation. . Jim Kyle■

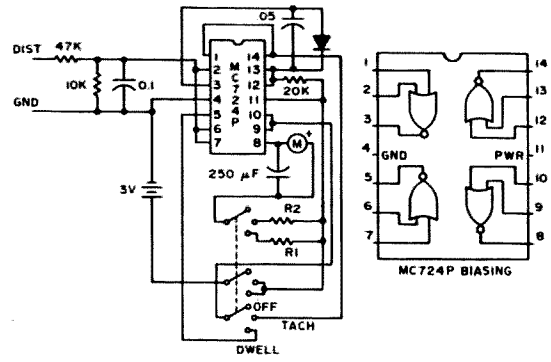

Fig. 19. Single IC chip provides tachometer and dwellmeter for auto enthusiasts. Tachometer uses one-shot formed by gates at terminals 1-2-3 and 12-13-14, with 20 kΩ timing resistors and 0.05 μF timing capacitor. Dwellmeter is driven by gate at terminals 5-6-7. Gate at terminals 8-9-10 is used only as meter driver, and capacitor across meter serves to damp individual current pulses. Power is supplied by 3V battery. Calibration is adjusted by R1 and R2.

VOX POP

Monthly Report of Activities on our Bands

Please send reports of interest on the band of your choice to Vox Pop, 73 Magazine, Peterborough, NH 03458. Use a postcard and indicate on the top the band being reported. Any news of interest will be considered grist for the mill...DX reports (including time, frequency, QSL manager), new FM repeaters, nets, emergency operations, contest high scorers, county operations, skip openings on VHF's, aurora, meteor scatter, moonbounce, anything you think will be of good general interest. The deadline for each issue is the tenth of the month. Material received April 10th will be scheduled for the June issue, which comes out in early May.

REPORT FORM

Please send all your reports to VOX POP on a postcard or QSL card, keep them as short as you can so we don't have to wear out our blue pencil. At the top of the card print clearly the band that the report is for. All reports will be listed by band, so if you are reporting on more than one band use more than one card.

(continued from page 75)

assembly and install in 12V base assembly.

NOTE:
The letters A and B are stamped on the bottom of the base assembly. Plug the crystal into the socket on the A side.

(4) Place the spacer plate between the crystal and the heater element and replace the cover. Make sure that the polarity of the cover and base agree.

(5) Insert the crystal assembly in the proper socket.

6 to 12V Conversion Power Supply

a. Vibrator Connections

(1) Disconnect the shielded lead from the two 2.9 mH choke coils located near the center of the chassis (Fig. 1).

(2) Disconnect the other ends of the two chokes from the two 0.5 μF capacitors (C4 and C5). These two choke coils are not used in the 12V circuit.

(3) Disconnect the black-yellow transformer lead from capacitor C4(0.5) and disconnect the red-yellow transformer lead from capacitor C5(0.5). Tape each lead separately and dress it out of the way.

(4) Disconnect the sleeve-covered lead from pin 3 of the vibrator socket. Use this lead to connect capacitors C4 and C5 in parallel. Do not solder the connections to C4 and C5 until completing step 15.

(5) Disconnect the black, yellow, and red leads from pins 1, 2, and 4 of the vibrator socket.

(6) Remove the lead between vibrator socket pin 6 and ground.

(7) Remove the 100Ω resistors connected between vibrator socket pins 1, 2, 4, and 5 and ground.

(8) Connect the red and black leads to the ungrounded terminal of C4 or C5 (changed to C104 and C105 on schematic).

(9) Connect pins 2 and 4 of the vibrator socket and then ground pin 4 at the ground lance near pin 5.

(10) Connect a 270Ω resistor from vibrator socket pin 1 to ground.

(11) Connect a 270Ω resistor from vibrator socket pin 5 to ground.

(12) Connect a 7.5Ω resistor from vibrator socket pin 6 to ground.

(13) Connect the yellow transformer lead to vibrator socket pin 1.

(14) Connect a 20Ω resistor from vibrator socket pin 3 to the ungrounded terminal of capacitor C4.

(15) Connect the shielded lead, which was disconnected from the 2.9 mH choke coil in step 1, to the ungrounded terminal of capacitor C5.

b. Push-to-Talk Relay Modifications

(1) Remove the white-black lead connected between terminal 8 of relay K1 and terminal 14 of transmitter terminal strip E2.

(2) Remove the white-black lead which connects between terminal 14 of terminal strip E2 and pin 4 of power plug P1.

(3) Connect a black-white lead from terminal 8 of relay K1 to terminal 4 of the power plug.

(4) At terminal board E1, disconnect the 24 AWG brown lead (running from the relay coil lug) from terminal 9. Reconnect this end of the lead to terminal 14 of terminal board E2.

c. Fuses

(1) Remove the two 15A fuses from the fuseholder.

(2) Paint out or use tape to mask over the markings on the fuseholder. It is recommended that 6.25A now be marked on the fuseholder to insure that oversize fuses are not used.

(3) Place two 6.25A fuses in the fuseholder.

d. Terminal Strip E1 Modifications

(1) Connect a 25 μF capacitor from terminal 9 to terminal 12 of receiver terminal strip. Connect the negative side of the capacitor to terminal 9.

(2) Connect a 25 μF capacitor from terminal 12 to terminal 15 of the receiver terminal strip. Connect the negative side of the capacitor to terminal 15.

That's all there is to it. The worthless old 6V surplus mobile is ready to go in your 12V auto.

DIMENSIONAL GEOGRAPHIC PROJECTIONS

A MUST FOR REMOTE REPEATER REPEATER

VHF * REPEATERS * FM * SHACK DECORATION *

Here is the last word in maps for the shack. . .three dimensional maps of your area. Maps are available for just about any area where there is mountainous or hilly terrain.

These maps are 18" high by 26" wide and are the most exact three dimensional maps ever made. The detail is incredible. Most maps have even the smallest dirt roads shown as well as altitude markings for every 100 feet and the height of taller mountains. Route numbers are given for roads; towers and other outstanding physical features are shown.

Using a repeater or planning one? You'll need this accurate 3D map to see your service area. Active on six or two meters? Use this map to back your rotating indicator.

These maps are made of permanently molded sturdy plastic, and come to you packaged flat in a large box.

The maps may be cut with a scissors and glued together to form a large mosaic wall mural. You'll need a wall 15 feet high to mount all of California. Each map shows a north-south area of 75 miles and an east-west area of 100 miles.

MAPS ARE $7.95 each, Postpaid!

Send cash; check, money order to DGP, Box 431, Jaffrey NH 03452.

Your maps will be sent to you within three to five weeks.

Send me____maps at $7.95 each No._____

Converting the AN SSQ-23A Sonobuoy to a 2W FM Rig

Al Denson W1BYX
Box 85
Rockville CT 06066

The AN/SSQ-23A "Sonobuoy" transmitter which has recently become available on the surplus market is one of those rare gems in today's depleted surplus market which is adaptable for amateur radio use with little work and low cost.

As originally made for the government, this unit was designed to be dropped into the sea from an aircraft as an expendable unit which detected underwater sounds by means of an underwater microphone. The original frequencies covered the range from 162.25 to 173.50 MHz.

A self-contained battery supply of 13V is tapped at 6.5V to feed a transistorized dc power converter. The normal battery drain was 2.25A total for both 6.5V sections. The dc power converter assembly is a small transistor switching unit which converted the 13V to 160V B+ for the transmitter.

The entire transmitting assembly consists of two printed circuit boards, the first of which contains a 12AT7 tube used as the rf oscillator and reactance modulator with a 6BQ7 used as a frequency doubler and power output stage. The second board contains two 12AX7s; one is used as an audio amplifier, the other as an amplifier/AGC audio network. Diode clippers were used for amplitude limiting of the audio component.

To convert the assembly to 2 meters, add one small 18 pF silver-mica capacitor in parallel with C206 as a pad to lower the output frequency. Connect a microphone to the input formerly used by the underwater "microphone" transducer and connect two 6V batteries in series to the power supply. Voila! You're on 2 meters FM, and ready to operate through the local repeater. And toned repeaters are no problem either; a tone oscillator may be very simply added by means of the built-in neon-tube relaxation oscillator circuit.

The schematic shows the 2W transmitter board only. The poor quality of the schematic is attributable to the fact that it was reproduced from a xerographic print of the original manual. . . . W1BYX ■

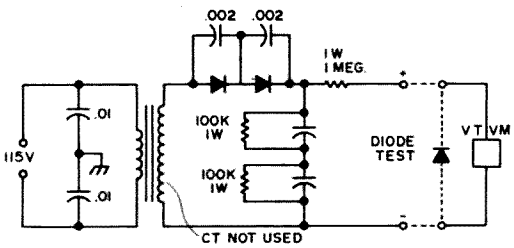
WHEN IT COMES TO ANTENNA SYSTEMS... IS YOURS

a space problem? a budget problem? an applications problem? an installation problem? or simply a problem of where to buy?

Your one-stop solution is ANTENNAS, INC.
Exclusively specialists in radiating systems, complete systems or any component part.
Arrays—complete or in kit form, quads, yagis, dipole assemblies, verticals—fixed or mobile, towers, masts, rotors, guy and control cable, transmission line, coax relays and switches, connectors and adaptors, test gear, technical publications, corrosion resistant hardware, corrosion proofing chemicals, insulators, installation and wiring hardware, aluminum tubing and plate, wire, and much, much more.
If your requirements are for a complete system, major components, or the smallest yet important piece of hardware—

Our prices and deliveries are hard to beat . . . anywhere.

ANTENNAS, INC. Dept. B, 512 McDonald Road Leavenworth, Kansas 66048.

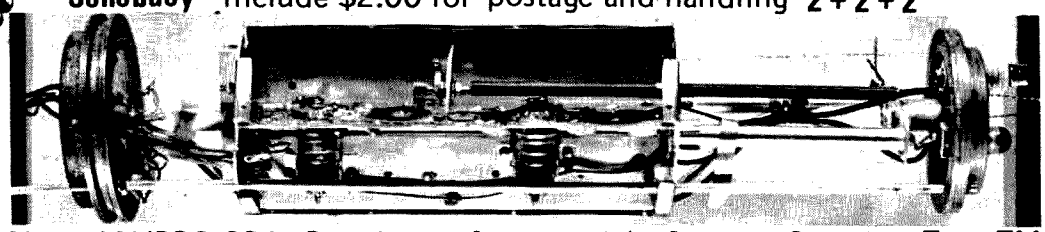


ANTENNAS, INC. can be your one-stop, single-source. Write today for our catalog . . . no charge of course.

EASY DIODE TESTING

Edwin Kirchhuber K4JK
2804 Broadview Drive
Huntsville AL 35810

With the advent of "bargain" diodes, we must test before using, especially if they are to be used in series (what else). The simplest method I have found is to use the good old vtvm and a power supply capable of providing 1000V. I used a 40 mA transformer (275-0-275V) in a half-wave circuit. The filter is a couple of 450V electrolytics in series. Any value from 8 to 80 μF is okay. The hot lead coming from the power supply has a 1 MΩ, 1W resistor in series to limit the current. The vtvm is placed across the diode test points and the readings are taken.



To check the characteristics of the "mystery" diode, put its cathode to the positive test point, and the anode to the negative test point. Read the voltage on the vtvm. If, for instance, it reads 300V, a safe PIV working voltage would be 2/3 of that — or 200V. To test for forward characteristics turn off the supply and reverse the diode. Set the vtvm to the 3V scale, turn on the power and read the voltage drop across the diode. It should not exceed 3V. Over that it is no good (open). No voltage indicates shorted diode.

To use diodes in series, select like units and be sure to use a capacitor across each to bypass the possible spikes that come from on-off operation of the power switch.

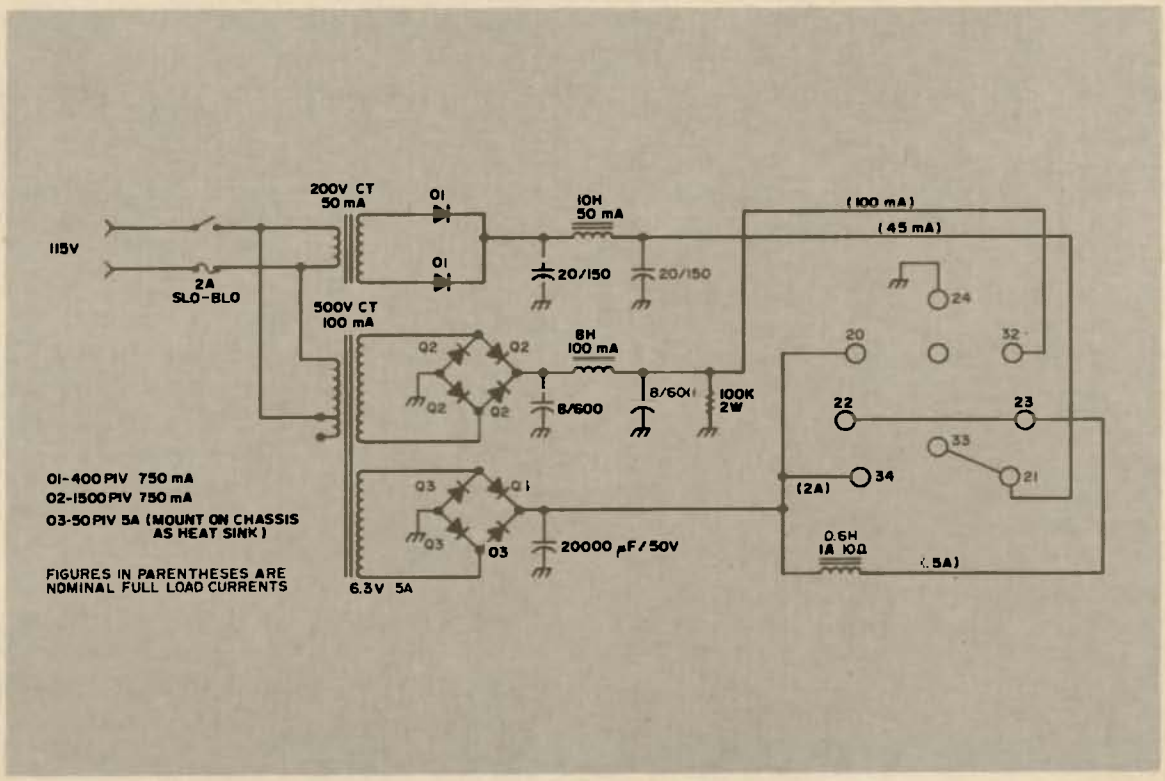
TURNING THE AN/GRC-9 INTO A NOVICE RIG

. . . and it puts out a husky 15W on CW.

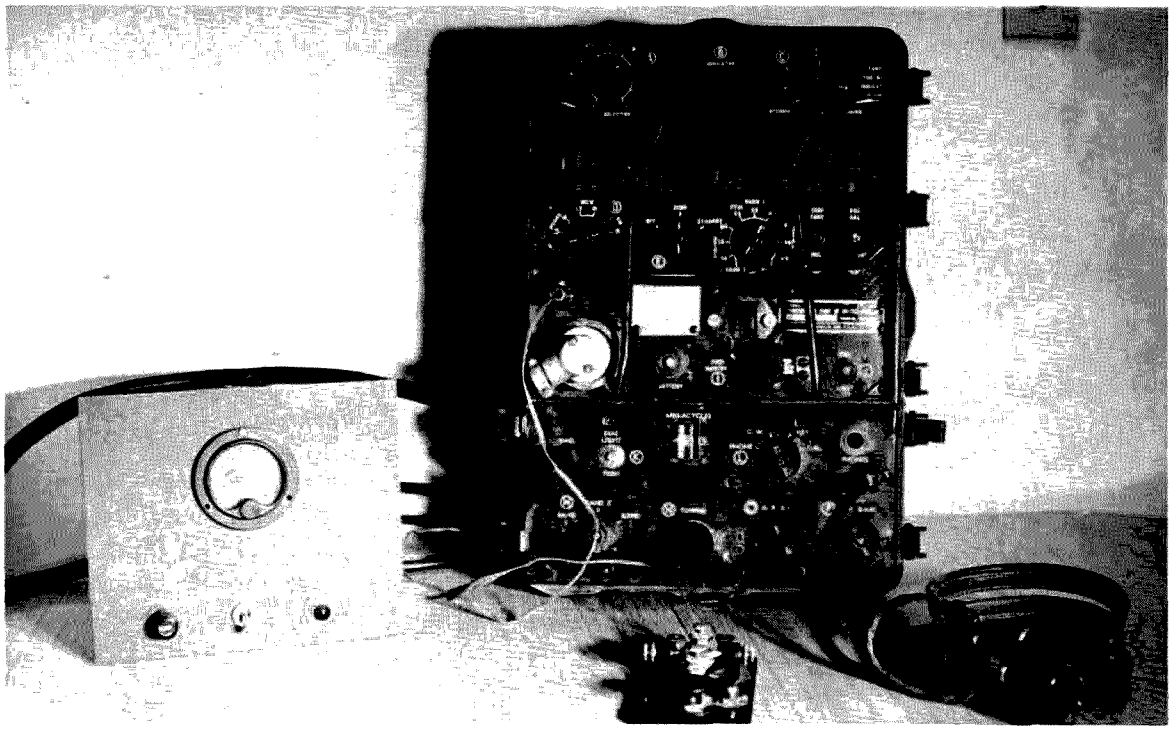
The surplus situation out here has been pretty bleak for quite a while, so I figured my luck was bound to change. While wandering through a local junkyard I noticed a small olive-drab box on the scrap pile. Inside was a compact transmitter–receiver covering 2 to 12 MHz! The junkie had decided not to melt it down because it had too little copper in it! After brief negotiations I parted with ten bucks and brought home the set. Since then I have run across others. They are apparently being phased out by the army. The sets I have seen have all required minor repairs, but the performance is well worth the effort.

The AN/GRC-9 is a small five-tube transmitter and seven-tube receiver designed for infantry packset use and for installation in vehicles. The receiver has a built-in 200 kHz crystal calibrator. The actual tuning range is from about 1.8 to 12 MHz so you can cover 160, 80, and 40 meters. The transmitter can be either crystal controlled or vfo. Full break-in is provided and there is a CW sidetone and provision for netting.

The set was designed for CW, MCW, and AM operation. The MCW mode is illegal, and the suppressor grid AM feature is practically worthless. However, CW performance is quite good. Power output is 15W, but can be increased. One of the best features is an ingenious antenna matching system that will match anything from a short whip to a dipole.



The first step in getting the set on the air is to supply power. For mobile or portable use the army used the PE-237 vibrapack, GN-58 hand generator, or DY-88 dynamotor. The PE-237 is available in quantity, but is useless. Reliability is terrible; it's bulky and the big vibrators are hard to find. The DY-88 is good and will operate from 6, 12, or 24V; but it, too, is quite bulky. The GN-58 hand-crank generator is fun for field portable use, but soon you run out of friends to turn the crank. The supply shown in Fig. 1 provides all necessary voltages and is easily run from a dc-to-ac inverter for portable operation. Incidentally, it will also operate the BC-1306, which is similar to the AN/GRC-9 but covers only 3.8 to 6.1 MHz.



Don't try to change the connector on the transmitter. Get a CD-1086 cable or a PL-279 connector. Watch out for the CD-435 cables. They are quite common and are identical in appearance to the CD-1086. If you get one it will have to be rewired as the pin for the +500V is jumpered to the 1.4V filament pin!

After completing the supply, carefully check your wiring and connect the supply to the set. Plug in phones (be sure the impedance switch at the back of the receiver is in the correct position), key, and antenna. The phone jack is also the switch for turning on the receiver filaments. Turn the power supply on and set control E to STANDBY or SEND. Set control A for the type of antenna in use. Set control D to CW–HI. Now measure the voltages. The metering socket, X-110, provides a convenient point for measuring the 6.3V filament and plate voltages. Pin assignments are stenciled on the back plate of the transmitter. The 2E22 plate voltage should be between 425 and 600V. Receiver plate voltage should be 105V, and the 6.3V filament shouldn't be less than 6.0V. The receiver filament voltage is measured on pin A of the BATTERY connector. It should be between 1.2 and 1.4V.

The controls are well marked and self-explanatory; the "net" provision turns on the receiver bfo and the transmitter vfo for zero beating. The calibrate position activates the 200 kHz crystal oscillator which is used

Fig. 1. Power supply for AN/GRC-9 and BC-1306 transmitter/receiver.

You can save yourself a lot of grief by using the connector already provided on the AN/GRC-9. In the photo here, the homebrew power supply (left) feeds the unit through its original mating connector on the front of the unit. After minimal conversion, all you need to do is add a key and a set of headphones as shown, and you're on the air.

for calibrating the transmitter vfo using the screwdriver-adjusted OSC/CAL adjustment (control H).

The transmitter's crystal oscillator always operates into a doubler stage, so the crystals must be chosen to be at half the desired operating frequency. Standard FT-243 types can be used. Provision is made for two crystal controlled channels per band.

With the power supply of Fig. 1, the transmitter will operate break-in in either the SEND or STANDBY positions. After a suitable warmup, tune in the desired signal on the receiver. Switch control L to NET and adjust the vfo for zero beat. Now switch L to CW. Set control A to the highest number for the type of antenna in use. Close the key and adjust control C for maximum brilliance on the indicator (which is an NE-16). This will coincide with maximum plate current. If no peak is observed, change A to the next lowest setting and repeat until a peak is observed.

As with all low-power sets, special consideration must be given to the antenna system. For really portable operation, be sure to have a good ground or get the counterpoise sets (CP-12 and CP-13) that were designed for use with the set. A doublet antenna made with 72Ω twinlead is recommended. Antennas AT-101/GRC-9 and AT-102/GRC-9 are specially designed longwires having jumpers for adjusting the frequency. These are desirable accessories.

In the PHONE position, the 2E22 filament is turned on by the transmit relay so there is a delay of about 3 sec after you press the push-to-talk switch. The 2E22 is a rare bottle to come by.

You can substitute an 807 by replacing the plate cap connector, clipping the lead going to pin 4 of the socket, and connecting pin 4 directly to the chassis. But the set will operate in the CW mode only now.

Don't jack up the plate voltage for the final amplifier over 600V as the rf components won't take it.

This set is excellent for the Novice as well as the portable CW enthusiast. Detailed troubleshooting information is contained in Technical Manual TM 11-263.

Part XIV: Measurement

Most of our discussion, so far in this Extra Class study course, has revolved around the theory of things—the "why" of the subjects covered on the FCC examination.

But you're undoubtedly aware that when theory and practice agree, at least one (and usually both) is probably in error—at least, so one of Murphy's famous laws would have us believe.

Actually, a properly framed theory must agree with what actually happens. If it doesn't, then it's not properly framed. There's just one rub—before you can compare theory and "what actually happens," you have to know what's "actually" happening. And that's where the fine art of making measurements comes in.

Measurements are an essential part of all electronics, for exactly this reason. They are the link between theory and practice. What's more, in ham radio measurements provide the assurance that your operation is within legal limits, both in the amount of power you use and the part of the rf spectrum your signal occupies. Since measurements are so essential, they are included in the Extra Class examination—and this time, we're going to concentrate on several aspects of the measurement problem which we haven't examined before.

We'll be covering the following questions from the FCC study list (as always, the numbers are those in the study list):

4. What precautions should be taken when measuring the rectified grid voltage in an oscillator with a dc voltmeter?

12. An oscilloscope is used to study the relationship between the input and output of an amplifier produced by a voice signal. How would the scope pattern display a linear relationship between the input and output signals?

35. How may an amateur check his transmitter for spurious sidebands?

37. Define the term decibel. How is the decibel used for voltage and power calculations?

60. How does a cathode-ray tube operate? What magnitude of voltage is normally used to bias the plates of a cathode ray tube? What purpose does this magnitude of bias voltage serve?

65. What means may be employed to measure low frequencies? High frequencies? VHF and UHF?

Rather than attempting to provide specific answers to these specific questions, we'll follow our usual practice of rephrasing the questions into more general terms covering the same subjects.

For openers, let's find out "How can we make accurate measurements?" Then we'll turn to rf measurements in particular by asking "How can we measure rf without lab equipment?" Having eliminated lab equipment, we will next turn our attention to an instrument which was considered only as lab

gear up until a few years ago as we find out "Why use an oscilloscope?" and finally we'll tackle a bit of unavoidable (but, we hope, not painful) mathematics by asking "What are dB?" All set? Let's get with it.

How Can We Make Accurate Measurements? In order to make accurate measurements, it helps to have a clear idea of just what "measurement" amounts to. We went through this in extensive detail in our earlier Advanced Class study course (now available as a book; order it!) and we won't go through it again, except to point out that any measurement is actually a comparison between an unknown quantity and a standard.

As it happens, only three basic causes of inaccuracy in any kind of measurement exist. If you can get rid of all three, you can't help but make accurate measurements. Unfortunately, we can never escape one of them, and so no measurement can ever be completely accurate. The best we can hope for is an *acceptable* degree of accuracy in our measurements. Just how accurate we must be to be acceptable is determined entirely by the purpose for which the measurement is being made. That is, if we only want to know whether our transmitters are generating output in the 80 meter band or on 40 meters, an accuracy of several dozen kilohertz is acceptable. But if we're hugging the band limit just as close as we dare in hopes of getting a better shot at some DX prize, then we need accuracy measured in hertz or even tenths of hertz.

The three basic causes of inaccuracy in measurement are: 1) improperly calibrated standards and/or instruments; 2) using the wrong instrument for the job; and 3) using the right instrument in the wrong way.

The inescapable inaccuracy in any measurement stems from the fact that perfect calibration is impossible. Even our "standards" have some small degree of built-in error. For most practical purposes this doesn't matter too much, but every now and then it fouls things up rather smartly. One example is in the measurement of frequency. Most of us take it for granted that WWV is an absolutely accurate standard of frequency. In point of fact, it is not. The accuracy of WWV is only about one part in 10,000,000,000,000. For almost any ham purpose, this is adequate, and our assumption is safe. When measuring time intervals of a microsecond or so, however, cumulative error can creep in from this source.

The more important side of our WWV example is that the signal has that accuracy only at the WWV transmitters! As soon as it leaves the transmitting antenna and is propagated several hundred to several thousand miles, often by way of one or more ionospheric jumps, the varying distance over which it travels introduces additional inaccuracies—and these cannot be compensated for by any techniques now known.

The problem was sufficiently serious, in this day of fractional-microsecond accuracies required for space probes, that a special low-frequency service was established to provide ground-wave propagation of the WWV signal on a global basis. This takes much of the propagation error out of the standard—but not all, and the standard isn't precise to begin with.

On a more practical level for us, any instrument which we use for measurements must be calibrated to some kind of standards, and the accuracy of the measurements made cannot be better than that of the instrument's calibration. Fortunately, for most ham purposes an accuracy of 2 to 5% is more than adequate. The only major exceptions are the measurement of frequency and of time, and for both of these far more accurate standards are readily available.

Mention of using the "wrong instrument" for any measurement may bring to mind immediately visions of an elaborate lab filled with exotic test equipment. However, for our purposes most of it is totally unnecessary. The ham who knows what he's doing and how to use the equipment he has can make almost any measurement he's ever likely to need with nothing more elaborate than a good vom, his regular station transmitter and receiver, and a moderately stocked junkbox from which to build any special adapters for special jobs.

It's a little easier if the list of test equipment includes a vtvm capable of reading both ac and dc voltages as well as

resistance; in this case the quality of the vom can be considerably less since its primary purpose then will be the measurement of dc. A scope helps too, but that's another question on our list so we'll ignore it for now.

Even with this restricted list of test equipment, it's not too difficult to use the wrong instrument for the job. A classic example, which has probably happened at least once to anyone who has ever used a voltmeter on both ac and dc voltages, is that of leaving the meter set for ac while measuring dc. The needle will still indicate, but the calibration is way off because the rectifiers necessary to measure the ac voltage offer some resistance to dc, and the scale calibration usually includes an automatic conversion from peak-to-peak or average readings (which is what the meter actually measures in almost every case) into rms readings, which are the values we usually use to refer to sine-wave ac voltage or current.

It's also spectacularly easy to leave the meter set on a resistance scale and attempt to measure high voltage; in this case, you usually have no doubt about the fact that something went wrong. Rather than attempt to straighten the bent needle, it's usually best to purchase a new meter!

But a little forethought and caution (and, let's face it, some bitter experience too) will help you avoid this cause of inaccuracy. By far the largest source of inaccuracy in most electrical and electronics measurements comes from using the right instrument, but using it in the wrong way.

The list of examples of using the right instrument in the wrong way is almost endless; we can show only a few. One of the more obvious is to attempt to measure a high value of resistance (say, a couple of megohms or more), using a vtvm on the highest scale. So far, so good. But just to make sure that the test probes are in good contact with the resistance being measured, let's grasp one in each hand and press it firmly against the terminal or lead it's supposed to touch.

Surprise! No matter what the actual resistance, the meter reading will usually be around half a megohm. For some people, especially on a hot and humid day, it will be much much less. After all, the human body has resistance too, and it varies from as little as 10,000 ohms up to two or three megohms (for dry skin). Putting this resistance in parallel with the resistance being measured plays hob with the measurement.

A more subtle error in the use of measuring instruments occurs whenever we forget that any meter requires *some* power out of the circuit being measured. In other words, the meter will load the circuit. This becomes most apparent when you attempt to measure the voltage between a hot chassis and ground, especially if the chassis is hot because of a very-high-resistance leakage path through supposedly good insulation. The "circuit" we're measuring in such a case is the series circuit from power line through several hundred thousand ohms of leakage resistance to the chassis itself, through ground, back to the grounded side of the power line. If a 25-megohm (input resistance) vtvm is used to measure voltage between the chassis and ground, you'll probably read about the same voltage as you would get from simply measuring the power-line voltage itself.

But a 20,000 ohm-per-volt (Ω/V) vom is adequate to make this measurement, if it's used properly.

Setting it to the 150-volt or even 300-volt ac scale, however, is not proper use. On those scales, the average hot chassis will measure out at only 30 to 50 volts—from ¼ to ½ the actual voltage present. Because on the 300-volt scale, the meter's total resistance is only about 1.5 megohms (a 20 kΩ/V meter typically has only 5 kΩ/V sensitivity on its ac ranges) and this, in series with approximately equal quantities of leakage resistance, cuts the voltage *at the meter* way, way down.

The proper technique, in this case, is to set the vom to its highest ac voltage scale and then make an educated guess about the reading. After all, if you measure anything over 80 to 100 volts you know something's wrong; absolute precision isn't necessary in this case. And on the highest scale, the meter's resistance is highest so that circuit loading is least.

The same principle applies to measuring avc voltages in receiver circuits, and fre-

quently to the measurement of screen-grid voltages (if they are obtained via series dropping resistors). The series resistance of a typical avc circuit is in the megohms; even a vtvm loads such a circuit slightly, and an ordinary vom will impose such a load that the measurement will not only be inaccurate but the circuit will fail to work properly so long as the meter is connected.

This whole business of "loading," incidentally, is the reason that the vtvm was invented in the first place. By using a dc amplifier between the test probe and the meter, less power need be taken from the circuit and so less load is imposed by the measurement.

When attempting to measure dc voltages in the presence of rf voltage, things get even trickier. Then an rf choke needs to be connected between the test probe and the measurement point, as close to the measurement point as possible, to keep the rf out of the meter and let only the dc through. At the same time, the possibility of loading the circuit down by too low an input resistance of the meter is present. A typical vom on the 50-volt scale offers only one megohm input resistance; many oscillators, for example, use 470,000-ohm grid-leak resistors. Shunting this with a 1-megohm load will cut the actual resistance in the circuit down to about 300,000 ohms, which amounts to a 33% reduction of the intended resistance. This may cause circuit malfunction.

If the need is to measure rf in the simultaneous presence of dc, the problem is even trickier. RF voltage measurements are usually made by use of an "rf probe" which is simply a crystal diode detector mounted at the end of a test probe. These usually include a blocking capacitor to keep dc out of the diode, but are also usually limited to voltages smaller than about 20 volts peak. If the rf voltage to be measured is greater than that, then a capacitive voltage divider needs to be rigged up to reduce the voltage applied to the probe into the 20-volt range. This, however, increases circuit capacitance—and would undoubtedly detune any oscillator.

The vom and vtvm, between them, will take care of just about any measurement of voltage, current, or resistance you normally need to make, except for the measurement of very small rf voltages (such as those present on the antenna lead-in from received signal). For these, we can use the station receiver—but not in the customary manner of just reading the S-meter. We'll look at this in a little more detail in our next question—for right now, the hint is this: remember that measurement is simply a process of comparison, and almost any indicating instrument has high accuracy when it's used to compare two quantities (in contrast with its undetermined accuracy as a measuring device all by itself).

To measure time, the station receiver comes into play again. Tuned to WWV, it provides a precise source of 1-second timing "ticks." For measuring much longer times, a clock or watch is a little handier—but the measurement of time is not, in the usual course of events, a normal electrical measurement.

To measure power, some professionals use a special wattmeter. We can achieve the same result by measuring voltage and current at the same time, and plugging them into the power formula. If the power we're measuring is rf, we simply use rf instruments. But these aren't on our list, so to manage with the instruments we have, we can rig up an rf probe to permit measurement of rf voltage and then measure the voltage present across a known resistance. Then we square the voltage and divide the product by the resistance, to get the power in watts.

To sum up, we can use the vom and vtvm, when we take the proper precautions to avoid loading down the circuit under test and to assure that only the desired power gets into the meter, to find out almost anything we want to know about dc, or about any qualities of ac which can be converted meaningfully into dc levels to drive the meters.

But we cannot use these instruments, directly, to make measurements of those qualities of ac which do not convert readily into dc levels. Some qualities of this type are the frequency, the waveform, and the distortion level of an ac signal. Another is the frequency distribution of a complex signal such as the output of an AM or SSB transmitter.

How Can We Measure rf Without Lab Equipment? Any mention of rf measurements, for most people anyway, stirs up immediate visions of highly specialized test gear such as spectrum analyzers, frequency counters, and the like. And let's face it, such equipment is nice to have if you can afford it—but most of us find it hard enough to keep a kilowatt in the shack, and would consider a 5–10 kilobuck outlay on one or two items of seldom-used test gear a needless extravagance.

If one has a spectrum analyzer, a sensitive rf vtvm, a wide-range frequency counter or EPUT (events per unit time) meter, and a good impedance bridge accurate over the entire rf spectrum, and also knows how to use all this gear, measurement of rf (and the special qualities of ac which are difficult to measure with common test instruments) is a snap. Just connect the right gadget in the right way, and read the result off the indicators.

But it's not exceptionally difficult to get the same or even better accuracy in rf measurements with no more test gear than we've already listed as being adequate for dc measurements—a good vom, the station receiver and transmitter, and a well-stocked junkbox.

To show the truth of this statement, let's go down the list of fancy equipment we just set forth and find out what each instrument does, then figure out how to do the same with our restricted set of test gear. We'll start with the spectrum analyzer.

The spectrum analyzer is a device which displays on a cathode ray tube a literal picture of some part of the rf spectrum, as it appears at the input terminal. The horizontal axis of the display represents frequency, and the vertical axis indicates signal strength. If only one signal is present in the band the instrument is set for, the display will be a horizontal line with a single vertical pip on it representing that single signal. If many signals of differing strengths are present, each will be represented by a vertical pip, and the height of the pip will show the relative strength of that signal.

The display looks exactly like the familiar graphs of the spectrum which appear in almost any textbook or magazine article which discusses it, and that's the main thing that makes the spectrum analyzer so convenient to use.

What the gadget actually amounts to, though, is a highly selective receiver with a circuit in it which automatically sweeps the receiver across the selected portion of the spectrum, while sweeping the beam across the crt face at the same speed. The receiver's output drives the vertical deflection plates of the cathode ray tube.

And there's the clue to our cheap-and-dirty version. We don't have to have the tube display. All we really need is to tune a selective receiver across the spectrum, noting down the relative strengths of every signal we encounter. Then we can take pencil and paper, and draw a graph which shows the same thing as the display would.

One of the major ham uses for this type of measurement is to check a transmitter's output for spurious emissions. The spurious emissions may be unwanted sidebands, splatter out of the desired channel, harmonics, or parasitics.

To make such a measurement on a transmitter, using the station receiver set to its most selective condition, the major problem is preventing overload of the receiver. The transmitter should (initially, anyway) be operated at minimum power, and be connected to a well-shielded dummy load rather than to an antenna. Even so, the chances of overloading a sensitive receiver are rather good. To test for possible overloading, disconnect the antenna cable from the receiver. Theoretically, you should not then be able to even detect your transmitter's signal—but few if any transmitters or receivers have this much shielding or filtering included in them. If you find the desired signal, but no others, you can proceed with the measurement; if you find spurious signals even under these conditions, they may be due to receiver overload—and they may actually be present in the transmitter output.

The simplest way to determine whether they are actually present in the transmitter output is to move the receiver to another location, leaving the transmitter operating into the dummy load. Alternatively, enlist the aid of another ham a half-mile or so

away. *His* receiver shouldn't be overloaded by your signal, if your dummy load is a good one (although the chances are fairly good that he will be able to find it). Increase power until his S-meter gives a comfortably high reading on your main signal, but not higher than S9. Then have him search the regions where your receiver indicated spurious signals. If the signals you found were the result of overload in your receiver, he shouldn't be able to locate them. Similarly, if they were actually present in your transmitter's output, they should be equally detectable to him.

If the spurious signals were due to receiver overload, then incase the shielding and filtering of your transmitter, receiver, or both. Most modern transmitters, in these days of potential TVI, have reasonably adequate shielding and filtering. Few hams do. The shielding and filtering required are the same as that required to TVI-proof a transmitter. Details, of course, will vary from receiver to receiver.

In order to describe the measurement technique, let's assume that your receiver passed this initial test and has adequate shielding and filtering so that the only signal you detected was your own carrier. Adjust transmitter power level to provide a convenient reference level on your receiver's S-meter with carrier alone. It need not be high, since it is merely a reference point. The level should be considerably higher than that at which you made the initial test, though, so that if any spurious signals are present in the output they will now be strong enough to be detected.

Now search the regions of the spectrum in which you suspect the spurious outputs might be present. If you find one, keep the receiver tuned to it and increase the transmitter's output until the strength of the spurious signal is equal to the reference level at which you set the carrier initially. Keep track of how much you had to increase the transmitter power to do this. The ratio of new transmitter power to original transmitter power, when converted to dB, will give you an accurate measure of the strength of the spurious signal.

The measurement of strength will be accurate, despite inaccuracies in your S-meter's calibration, because the S-meter is used only as an indicator or reference point, and not to make the measurement itself. To put it another way, the S-meter only tells you when you have increased power enough to make the spurious signal as strong as the carrier was originally. The *measurement* is the comparison of transmitter power in the beginning and transmitter power necessary to bring the spurious signal up to the strength of the original carrier.

Checking across a wide stretch of the spectrum by this technique is a tedious business—but we never claimed it would be quick. It *is* a practical way to check for spurious output, with little test equipment. It can also be used to check the modulation index of an FM signal (by locating the point at which carrier disappears as modulation index is increased), and with minor variations to check both carrier and sideband suppression of an SSB signal.

The station receiver can also double as a sensitive rf vtvm. The rf vtvm is, essentially, an instrument for measuring rf voltages which are very small to begin with. If an accurate measurement of the voltage is desired, an accurate standard for comparison will be necessary—but most uses of rf vtvm are more concerned with the presence or absence of rf voltage at some specific frequency, or its relative strength as some adjustment is varied, and for these no standard is needed.

The procedure for using the receiver as a vtvm is essentially the same as that for making a spectrum analyzer of it. You tune in the signal, and use the S-meter as an indicator of signal strength.

If your receiver has no S-meter, don't let that stop you. Simply connect your vtvm to the avc line (most easily located at the cold end of the first i-f transformer, where a bypass capacitor and isolation resistor should be connected) and measure the relative voltage there. If you have no vtvm, it's still possible to get a fair indication by connecting the vom to measure screen voltage on any controlled i-f tube; unless the screens are fed from a regulated source (and in a well-designed receiver with avc, they won't be, because the variation of screen voltage with avc level helps smooth out the

avc action of the receiver and compensate for some nonlinearities inherent in the design of the tubes) this will give you the desired measure of signal strength. Screen voltage will rise with increasing signal strength, as the avc voltage reduces the tube's cathode current.

The frequency counter or EPUT meter is a bit more complex to simulate with a restricted list of test gear, because its purpose is to measure frequency of an ac signal over a very wide range, and the cheap-and-dirty techniques cover only limited ranges.

A frequency counter consists of several different kinds of circuits. One actually counts the individual cycles of the signal and tallies them up on the visual indicators. Another provides an accurate time reference. Still another acts as a gate, to apply the input signal to the counting circuits for a specified period of time and then to shut it off.

All together, the circuits actually count the number of cycles of the input signal which occur during the time the gate is open, and display the resulting count on a set of indicators. If the input signal is ordinary 60 Hz ac power and the selected time interval is one second, the resulting count may be 59, 60, or 61, depending upon what fraction of a cycle happens to get cut off at the beginning or end of the one-second measurement interval.

Setting the time base to 10 seconds provides an extra digit of accuracy. The indication now will probably be 59.9, 60.0, or 60.1. Going up to a 100-second base adds still another digit, but your power company probably doesn't keep the frequency any more constant than 0.1 Hz either side of the nominal 60.

Most commercial frequency counters offer at least 5-digit readings, but few of them offer time bases longer than 100 seconds. The frequency range usually runs from 1 Hz or so at the low end, up into the VHF region, with time bases as short as a microsecond for measurement of very high frequencies.

To measure frequency in the ham shack, it's not very practical to attempt to duplicate the frequency-counter approach. Instead, we usually divide the ac spectrum into three or four different ranges, and use different techniques for each. For everything except VHF and above, the basic technique is that of comparing the unknown frequency to a known standard.

At audio frequencies, our standards can be 60 Hz ac from the power line, tuning forks, or the 440 Hz and 600 Hz signals broadcast by WWV. Another standard sometimes used is a well-tuned piano.

The ear can be used as a comparison device with surprising accuracy; while few persons have perfect pitch, most of us can tell when two tones differ in pitch—so if enough standards are available, at least one is likely to be fairly close in frequency to the unknown signal.

A variable-frequency audio oscillator can be calibrated by comparison against several standards, and then used as a secondary standard for comparison to the unknown, with the ear still serving as a zero-beat indicator.

Yes, we know a variable-frequency audio oscillator wasn't on our list of equipment—at least, not under that name. But the bfo of the station receiver, together with any source of steady-frequency rf such as the transmitter's oscillator, provides a most handy source of audio tones, and is usually continually variable throughout the audio range!

To increase accuracy of such measurements, a scope can be used as an indicator of zero-beat rather than trusting the ear. Just connect the scope's vertical input leads across the variable audio oscillator's output, and the horizontal input leads to the unknown signal. If the two signals differ in frequency, the tube will display a pattern of varying complexity. When the frequencies become identical (zero beat), the pattern will be either a straight line, a circle, or an ellipse. If it's an ellipse, it may appear to be rotating, and shift through the circle and straight-line conditions as it rotates. This indicates a very slight difference in frequency; the difference in cycles per second is equal to the number of times per second the pattern rotates. Keeping this in mind, it's easy to measure a *difference* of as little as 0.01 Hz in the two frequencies; whether the

final frequency measurement has this accuracy will be determined entirely by the accuracy of the standard you're using.

When the unknown frequency is above the audio range, the same basic technique is still used but the source of frequency standards differs. A standard-frequency crystal oscillator is handy to have in this case; refer to your junkbox and rig one up. Zero-beat it against WWV, using the af measurement technique to get as much accuracy as you can. You now have a source of rf of known frequency—the usual standard is 100 kHz.

The frequency of the unknown signal is first approximated by comparison to other signals of known frequency. Then you turn on the frequency standard, and count harmonics of it from some known point. An easy point for most of us to locate in any ham band is the lower band edge; this is also, always, a harmonic of 100 kHz, and so when the receiver is tuned approximately to the lower limit the harmonic of the standard will mark the exact band limit. Other known points in the spectrum may be located in the same manner—if necessary, by counting multiples of 100 kHz from the nearest ham band.

The 100 kHz standard permits the unknown signal to be bracketed between two points 100 kHz apart, and it's usually not too difficult to determine which of these two it's closest to. This locates the frequency of the unknown signal to someplace inside an area 50 kHz wide; for many purposes this is close enough. If not, we call upon a second frequency standard. This is a multivibrator or frequency divider, slaved to the 100 kHz unit, which provides a 10 kHz signal as accurate as the 100 kHz original. By switching it on, and counting harmonics as we tune up from the known 100 kHz harmonic, we can bracket the unknown signal between two 10 kHz harmonics of known frequency.

If even this isn't accurate enough, we're not done. The 10 kHz frequency is within the audio range, and we've bracketed our unknown between two of these points so the error in our measurement this far cannot exceed 5 kHz. All we need do is measure the beat frequency between our unknown and the nearest 10 kHz harmonic (that is, the lowest frequency in the receiver's output), using audio measurement techniques, to locate the unknown frequency to an accuracy limited only by that of our standard.

This technique for measuring rf frequencies works equally well from the bottom of the rf region up to the VHF area; as frequency increases, the number of 100 kHz harmonics becomes a bit large so that VHF workers customarily use still a third standard oscillator set to 1 MHz to obtain a good starting point, but the technique remains basically unchanged.

By the time we get to 50 MHz or so, however, the strength of the 10 kHz harmonics is getting a bit weak. Somewhere in this region, most of us switch to a completely different measurement technique which depends upon the constant relationship between frequency and wavelength. Rather than measuring frequency in terms of time, it becomes easier to measure wavelength in terms of distance.

For this, we use what are known as Lecher wires. The term presumably has nothing to do with dirty old men. A set of Lecher wires consists essentially of a parallel-wire transmission line which is at least one wavelength long. For 50 MHz use, that's just under 20 feet. One set will suffice for all measurements. In addition to the two taut parallel wires of the transmission line, which must be uninsulated and supported only at their ends, we have a shorting block which shorts the two together and which can be moved the length of the wires, and a connector at one end to connect the wires to the transmitter output. Often, the shorting block includes some indicator of rf current such as a pilot lamp. In another version of Lecher-wire technique, the short is left permanently in place at one end of the wires and the transmitter is connected to the other end; in this case, an indicator of rf voltage is arranged so that it can be moved the length of the wires to measure voltage between the two conductors at any point along their length.

The idea behind the Lecher wires is that every condition which exists on a transmission line will exactly repeat itself every full wavelength down that line, and many conditions such as peak absolute voltage

(without regard to phase) will exactly repeat every half-wavelength.

Thus if a transmitter is coupled to a set of Lecher wires with the shorting bar set at the far end, and adjusted for a specific amount of plate current at resonance, and then the shorting block is moved closer to the transmitter, the conditions under which the transmitter's output stage operates will change as the shorting block moves. When the block has been moved exactly a half wavelength, however, the conditions will have returned to the exact duplicate of those at the start, and the plate current will again be what it was at the beginning. Simply measuring the distance through which the block was moved and multiplying by two tells us the wavelength; converting wavelength to meters and dividing the result into 300 gives us the frequency in MHz.

As described, the Lecher wires can be used only to measure frequency of a transmitter, and that is their most usual use. They can, however, be used as a tunable trap to trap out the signal, and thus can be used to measure frequency of signals other than those produced by a transmitter—if you have a receiver capable of detecting the signal being measured. The technique is similar; the signal being measured is coupled to the receiver, and the Lecher wires are connected in parallel with the receiver input. The receiver S-meter, or a similar indicator rigged up as we discussed earlier in connection with rf vtvm's, is used to indicate signal strength. At some positions of the shorting bar, signal strength will reach maximum, and at other positions of the shorting bar, signal strength will be minimum. The distance between two points of either maximum or minimum strength will be a half wavelength; you can use whichever is easiest to detect.

The impedance bridge is a device for measuring the impedance of any circuit at any specific frequency, and this is the hardest of all the lab-type instruments to duplicate in a cheap-and-dirty version with limited test gear. Fortunately, its major use for ham purposes is in the matching of antennas to transmitters and feedlines, and this application can be simulated by simple measurement of swr on the feedline.

To measure swr on a feedline, locate a point on the feedline at which the rf voltage is at a maximum. This is simple with open-wire feedlines and not too difficult with twin-lead, but coax poses a difficult problem not easily solved. When the rf voltage maximum is located, if the frequency is known you can find the voltage minimum point a quarter-wavelength in either direction from the maximum point. The vswr is simply the ratio of maximum voltage to minimum voltage.

At sufficiently high frequencies, a variant of the Lecher wires can now be used to adjust the swr to unity. This consists of a length of open-wire transmission line with an adjustable short, at least a half wavelength long, which is connected across the load (or, alternately, at some multiple of half a wavelength back from the load). By moving the short along this line, the swr can be changed to anything from unity to infinity. The principle is that the impedance of the "tuning stub" changes from zero to infinite as the shorting stub moves through a quarter wavelength distance, and is either capacitive or inductive, depending on whether the stub's effective length is greater or less than a quarter wavelength.

When the stub is adjusted to bring swr to unity (1.0 to 1), then the impedance of the stub is exactly canceling any reactance in the load itself, and the resistive element of the stub's impedance is bringing the load's resistance to a match as well. The impedance of the stub can be calculated from its length, and a bit more calculation will reveal the impedance of the load.

This technique is actually that employed in most microwave labs; instead of a "tuning stub" they call the adjustable element a "slotted line," and they perform the calculations graphically by means of a "Smith chart." The result is the most accurate measurement now possible of rf impedance at very high frequencies—but it's more trouble than most of us find convenient.

Why Use An Oscilloscope? You may recall that our list of minimum test equipment did not include an oscilloscope, yet the scope is one of the most convenient of all test instruments to use and many hams working with RTTY or sideband feel that

the scope is as indispensable as a receiver or a transmitter. Let's examine the instrument in detail and find out why it's so convenient.

An oscilloscope—any oscilloscope—is built around a cathode ray tube. In addition to the tube itself, the scope includes power supplies. Most scopes also include amplifiers to drive both the vertical and horizontal deflection plates of the tube, and a horizontal-sweep circuit of some type to provide a "time base."

The differences between scopes are, for the most part, differences in the deflection amplifiers and in the horizontal sweep circuitry. An inexpensive "general-purpose" or "service" scope typically has a vertical deflection amplifier with frequency response from the subsconic up into the low rf region (5 Hz to 500 kHz, frequently), a horizontal amplifier with more restricted bandwidth, and a sweep oscillator which provides a sawtooth waveform from 15 to 20 to 200,000 pulses per second.

More expensive "service" instruments often provide a vertical-amplifier frequency response from dc up to 4 or 5 MHz, to provide the capability of viewing all key waveforms in a color-TV chassis.

"Lab-type" scopes are more elaborate; they may provide amplifiers with frequency response from dc up to 50 or 100 MHz, with much more accurately calibrated "triggered-sweep" or even "delayed sweep" time-base circuits. The "X-Y" scope has identical vertical and horizontal amplifier circuits. There are almost as many variations as one can imagine.

But while the variations among scopes lie mainly in the associated amplifiers and time bases, the heart is the cathode ray tube itself; it provides the characteristics which make the scope useful.

Like any other vacuum tube, the cathode ray tube (crt) contains a heater, a cathode, and a grid. But there the similarities end. Instead of a plate, the crt contains several additional electrodes known as "focus" electrodes, and an "accelerator" electrode. In addition, the crt's used in most scopes contain two pairs of "deflection plates." And finally, the "face" of the tube is coated on the inside with a "phosphor," which is a substance that glows when struck by rapidly moving electrons.

The heater brings the cathode to a temperature which permits electrons to boil off its surface, and these electrons are attracted toward the focus and accelerator electrodes, passing through the grid structure en route.

However, the shapes of all these electrodes are such that the electrons—at least, most of them—never reach either the focus electrode of the accelerator directly. Instead, the same electric forces which attract the electrons away from the cathode shape the stream of electrons into a tight beam, which passes through appropriately shaped openings in the focus and accelerator electrodes and goes on to strike the phosphor at the tube's face.

Once the electrons hit the phosphor, they can bounce back in all directions inside the tube and thus make their way to the accelerator, completing the electric circuit. When the electron beam strikes the phosphor, though, it creates a glow where it hit—and that's the whole purpose of the crt in the first place.

The intensity of the glow depends on the number of electrons which hit the screen (phosphor), and this is in turn controlled by the grid-cathode bias of the crt just as in a conventional vacuum tube.

The physical size of the beam depends upon the balance of the forces which shape the beam in the first place, and so is affected by many things. The beam intensity, the speed at which the electrons are traveling, and the relative voltages between focus electrode and cathode and between focus electrode and accelerator all have some effect upon beam size. The major control of beam size is the voltage present between focus electrode and cathode. If the other factors are in the right general area, the voltage on the focus electrode can be adjusted to shape the beam into the smallest possible physical size—or, by analogy with optics, to "focus" the beam to an apparent point.

The speed at which the electrons in the beam are traveling is determined by the voltage between accelerator and cathode. The greater the voltage, the faster the beam.

Since the electrons are packing more energy when they move faster, this will also affect beam intensity. Most crt's operate with voltages of 1 to 25 kV between accelerator and cathode; typical values for a 5-inch crt would be about 2000 volts. The high voltage is required because of the physical distance between cathode and accelerator, and also in order to establish the proper "electron ballistics" to permit focusing action. While the voltage is high, the current is very small, normally being in the microampere range.

The combination of heater, cathode, grid, focus, and accelerator is known as an "electron gun." The electron gun supplies a steady stream of electrons in a nice tight beam, but all that does on the screen is produce a single intense dot of light. For the tube to serve any useful purpose, that dot must be moved about on the screen and that's the purpose of the deflection plates.

The two pairs of deflection plates are arranged at right angles to each other, so that the beam passes halfway between the two plates of each pair on its way from electron gun to screen (some crt's use "postdeflection acceleration," with an additional accelerator between deflection plates and screen, but this is a complication we won't go into here; the principles are similar).

The electrons in the beam are, of course, negative charges, and are subject to the laws of electrostatic attraction and repulsion. Thus, if one plate in a pair is made positive with respect to the beam, the beam will be attracted toward that plate. If the other plate goes negative at the same time, the beam will be repelled from the negative plate and attracted toward the positive one. By independently adjusting the voltages on each pair of plates, the beam can be moved to any desired location on the crt screen.

In practice, both plates of each pair are usually kept at approximately the same voltage, which is usually 150 to 300 volts more positive than the accelerator. To keep things within reasonable limits, many scopes have the crt hooked up so that its cathode is 2000 volts negative with respect to ground, its accelerator is at ground level, and the deflection plates are 200 to 300 volts positive to ground. This permits direct connection from the deflection amplifier plates to the deflection plates of the crt for better low-frequency response, and all the high-current voltages are kept to moderate levels. In such a hookup, the deflection plates are still around 2200 volts positive with respect to the crt cathode, however. The exact ratio of voltages between one plate and the other of each pair is adjusted as necessary to put the electron beam in the center of the screen with no signals applied; this is the purpose of the "centering" controls on the scope.

The signals to be displayed on the scope are then applied to the deflection plates, and thus move the spot around the crt screen in a manner determined by the waveform and intensity of the signals. If a sine-wave signal is applied to the vertical plates while a sawtooth signal is applied to the horizontal plates, the resulting spot movement will trace a conventional "picture" of the sine-wave on the screen.

Like the more conventional dc meter movement, the scope changes an electrical force into visible movement of something. Where the ordinary meter moves a pointer which has considerable weight and limited speed of response, however, the scope is moving an electron beam which has, for all practical purposes, no weight or inertia at all and so is capable of almost unlimited response speed. An ordinary dc meter cannot follow the fluctuations of a 20 Hz signal rapidly enough to be read conveniently; an ordinary scope can easily display variations in a 50 MHz signal, if its deflection amplifiers are bypassed and the signal connected directly to the deflection plates.

This rapid response, and the ability to draw waveform pictures which correspond to the way most of us imagine waveforms, are the two features that give the scope its chief value. There's something about actually *seeing* a signal that no amount of indirect measurement can provide.

We've already mentioned the use of the sawtooth or "time base" horizontal sweep for waveform viewing, but the scope is equally useful as a direct comparison instrument. If one signal is applied to the vertical plates and another signal to the horizontal plates, the resulting display on the screen

will be an instantaneous comparison of the two signals. If one signal is an unknown frequency while the other is the known standard (or, better yet, an adjustable-frequency secondary standard), the screen display will provide an indication of the relationship between the two frequencies. If the display is a stationary pattern, the unknown is an exact harmonic of the standard or vice versa; at any rate, one of the frequencies is an exact multiple of the other. If the pattern moves, the relationship is not exact.

The signals being compared do not have to be completely separate signals. A signal can be compared against itself. If the same signal is applied to both the horizontal and the vertical plates, the screen display will be a single line inclined at a 45 degree angle from the horizontal. If the vertical plates are fed by the signal from the output of an amplifier's input, the display will show the effect of the amplifier on the signal. Since the amplified signal is stronger than the input signal, the vertical deflection will be greater than the horizontal and the display will be moved nearly vertical. If the only thing the amplifier does to the signal is to amplify it, this will be the only difference in the displayed signal. If the amplifier also introduces distortion, though, the vertical plates will get the distortion components of the signal and the horizontal plates will not—and the display will no longer be a straight line! Instead, it will show "squiggles" indicating the presence of distortion.

If the amplifier changes the phase of the signal, the display won't be a straight line either—instead, it will be an ellipse or a circle (which depends upon the amount of phase shift introduced by the amplifier).

Since this comparison is essentially that of a signal against an amplified version of itself, it can be used at any frequency to which the deflection plates can respond. In practice, this means any frequency below the UHF region.

If linearity of an rf amplifier is being checked by this method, though, it's often more convenient to modulate the rf, then use detectors at both the input and output test points to convert the modulated rf to audio and make the actual comparison on the audio components rather than the rf itself. When this is done, the scope's internal amplifiers can be used, and the effects of the amplifier's gain canceled out by amplifying the input-side signal a corresponding amount more than the output-side signal. This often makes the distortion easier to see, since it is normally very small in comparison to the original signal level.

What are dB? It's almost impossible to do anything in radio any more without running into "dB," the abbreviation for "decibels." It's also almost impossible to find anyone capable of giving a brief yet clear and accurate description of what these beasties really are. Let's give it a try, anyway.

The word "decibel," itself, is the standard metric-system indication for a unit of measurement which is one-tenth of a "bel." This doesn't help much, because even fewer persons are familiar with "bels."

The "bel" is the unit of power ratio, and simply indicates a 10-to-1 power ratio. A 100-watt amplifier is one "bel" more powerful than is a 10-watt unit, and similarly the 10-watt unit is one "bel" more powerful than a 1-watter.

This makes it appear that a 100-watt rig would be only two "bels" more powerful than a 1-watt outfit—and that's exactly right. Each "bel" indicates an additional 10-time increase in power, so that two "bels" means 10 times 10 or 100 times as much power.

It only takes six "bels" to make a million-time power increase. Sailors who are used to the expression "eight bells and all's well" would be floored if they were talking about "bels" instead of "bells," because that's a power ratio of 100 million to 1.

Obviously, the "bel" is far too large a unit for comfortable use. That's why "decibels," which are only one-tenth as large, are the unit in common usage.

It might appear that, since a decibel is 1/10 of a bel and a bel is a 10-to-1 ratio, a decibel would be 1/10 of 10-to-1 or simply a 1-to-1 ratio. However, that's *not* the case, and the reason is far from obvious. It comes about because of the way in which the ratio is converted into a number to make the "bel" unit in the first place. To get one "bel" from a ratio of 10, or two "bels" from

a ratio of 100, what we really did was simply count the zeros in the ratio. The number "10" has one zero, so that's one bel. Similarly, 100 has two zeros, so it's two bels. A million is written as "1" followed by six zeros, and so it's six bels. And so forth.

This business of counting the zeros is the first step of the mathematical process called "taking the logarithm" of a number. If the number happens to be an even multiple of 10, it's also the last step of the process as well—but if it's not, there's much more to it. The "bel" is thus defined as the *log* of the power ratio.

When we stepped down from the massive "bel" to the more conveniently sized "decibel" we applied our factor of 1/10 to the *unit* itself, not to either the ratio of the log of the ratio. The bel is still what it always was; it just takes 10 times as many decibels to make a bel. Since the bel is the log of the power ratio, this means that 10 dB = log (P1/P2). One dB, then, would be 1/10 of log (P1/P2); we usually write this equation a little differently. We turn the ratio upside down so that the log gets multiplied by 10 rather than divided, and come out with the formula you'll find in all the textbooks: dB=10 log (P2/P1).

We've made this brief excursion into "logs" and equations just to show where the formula came from. In actual practice, you don't need slide rule or log tables to work with dB to as much accuracy as is ever needed in any radio work.

All you need is the knowledge that an additional 10 dB is a 10-time power increase, 100 dB is 100 times, etc., plus a knowledge of the ratios indicated by each dB value from 0 through 9. Even of these 9 ratios, you'll normally use only a couple.

The ratio for zero dB is 1 to 1. If an amplifier is rated for 0 dB gain, its gain is exactly one. To see this most easily, convert the dB back to bels for a moment. Ten times zero is still zero, so 0 dB equals 0 bels. The number of bels, we recall, is equal to the number of zeros following the "1" in the power ratio. One followed by no zeros remains one, so the ratio is 1 to 1.

The most important dB-to-ratio number to remember is that for 3 dB. This is a 1.995-to-1 power ratio, which is so close to being 2-to-1 that nobody ever pays any attention to the difference. Remember it as 3 dB equals twice the power.

Back at the beginning of this question, we saw that *adding* dB (or bels) is the same as *multiplying* the power ratio. It follows, then, that 6 dB should be just barely less than a 4-to-1 ratio. The actual ratio is 3.931 to 1, but 4 to 1 is close enough for any practical work again.

A single dB is a ratio of 1.259 to 1; the easiest way to remember this is as 5-to-4 ratio, or 1.25 to 1. You don't really need to remember it, except that it gives you the ability to figure out the ratio for any other number of dB.

For instance, working from the 5/4 ratio for 1 dB, we would get ratios of 25/16 for 2 dB and 125/64 for 3 dB.

Let's see what happens when we use both the 3 dB and 1 dB values this way to calculate the ratio for 10 dB (which we already know is really 10 to 1): To tally up 10 dB from our 3 and 1 dB figures, we get 2x2x2x(5/4). This comes out to 40/4, or exactly 10 to 1. The small errors in both the 2-to-1 figure and 5-to-4 figure have canceled each other out.

If we did it with nothing but the 1 dB figure, we would multiply 5/4 by itself 10 times. This comes out to be 9765625/1048576, or a ratio of 9.3+ to 1. In this case, our error has accumulated a bit. The moral is clear; when you figure out the other values, use both the 3 dB and 1 dB values to keep the error to a minimum.

Now let's use these facts we have memorized to find out the power ratio indicated by 37 dB. First, we dissect the number "37" into its components, 30+3+3+1. The "30" gives us a ratio of 1000/1. Each "3" gives us a ratio of 2/1, and the "1" gives us a ratio of 5/4. The total "37" must, then, mean a ratio of 1000/1 times 2/1 times 2/1 times 5/4, or 4000/1 times 5/4, which works out to be 20,000/4 or 5000/1. An amplifier rated for 37 dB gain would, then, produce a power ratio from output to input of 5000 to 1. A hundredth of a watt at the input would produce 50 watts at the output.

You may have noticed that we've only looked at positive dB figures. Often, ratings

are expressed in negative dB. While it's just as easy (or difficult, as the case may be) to work the math for negative as for positive logs, the simple way out is to always think in terms of dB without sign, and then read the sign as meaning "gain" or "loss." Positive dB indicate gain and negative dB indicate loss. An attenuator rated for −37 dB from input to output still involves a 5000/1 power ratio, but now it's in the other direction and the output power is only 1/5000 as great as that at the input.

"Great," we can hear you mumbling, "but what about dB of voltage or current? All you've mentioned yet have been *power* dB, and most of the time we use the other kind!"

Relax. There *is* no other kind. Decibels, *any* decibels, always indicate power ratio. Granted, the textbooks show you a different formula if you're dealing with voltage or current measurements—but that's just to keep you from having to convert the voltage or current into power by using Ohm's law before making the dB conversion.

And since that "other" formula—the one that says dB=20 log (E2/E1)—*is* a combination of the dB formula, the power equation P=E x I, and Ohm's law all wrapped up in one package, it can get you into big trouble with the kinds of questions the FCC puts on its exams.

If, on the other hand, you fix firmly in mind that dB are measures of power ratio and nothing else, you can't go wrong. If the problems fails to mention power and gives you either current or voltage instead, just convert the current or voltage to a power by plugging it into the power equation. Then use the decibel relationships we've already examined.

Many times, both on exams and in practical work, you may find that only a voltage or a current is given; there's only half the information you need to figure out the power. What then?

If the two voltages being compared are both being measured across the same (or equal values of) resistance, you can get the power by squaring the voltage and dividing by resistance. This is just a combination of the power equation and Ohm's law; Ohm's law tells you the current given the voltage and resistance, while the power equation tells you the power when current and voltage are known.

As a matter of fact, this can be done even when the resistance values differ! And when the resistance values are equal or the same, you don't even have to know what the resistance is, because when you take the ratio of the two power figures, the resistance will cancel itself right out of the calculation.

That means that all you have to do is use the *square* of the voltage in place of the power figure, and everything we've said about dB will still hold true. But this will work *only* if both voltages are measured across the same resistance value; if the input voltage is measured across one value of resistance and output voltage is measured across some other resistance value, then all bets are off. For example, you might measure 1V at the input of an amplifier across a 1-megohm resistor, and find 1V at the output across a 10-ohm load. If you simply work with the voltage ratios, you have 1/2 or 0 dB ratio. But 1V across one megohm is just a microwatt (1/10000000 watt), while 1V across 10 ohms is 1/10 watt, so the amplifier itself must have a power gain of 100,000—which is 50 dB!

In the one very special case of identical resistances, however, the ratio of the squares of the voltages can be used in place of the power ratio; now as it happens, one of the nice properties about log-type numbers is that the log of the square of any number is just two times the log of the number itself. Similarly, the ratio of the squares of two numbers is exactly the same as the square of the ratio of the two numbers—you can take the ratio either before or after squaring, so long as the end result gets both the input and output voltages squared. That means all we have to do to the "power" or universal version of the dB formula is plug in "E" instead of "P," and multiply by two—which is where the "other" formula applies only to a single special case, while the "power" version applies to everything.

VHF FM & ...YOU

Why has this mode made such a sweeping impact on amateur radio?

The past few years have shown a marked increase in the number of amateurs operating on the 50 MHz, 144 MHz, and higher frequency bands. Many of these amateurs are using surplus or obsolete commercial FM equipment. This rise in FM activity is due to several factors, including the availability of equipment and the need for reliable single-frequency communications. The availability of equipment is due to two prime factors: The "splitting" of commercial FM channels has rendered many older units unsuitable for commercial use. Also, recent trends in miniaturization have made many units obsolete in terms of size, reliability, and battery-power consumption.

The need for a reliable single-channel system stems from several factors: The

average American is much more "mobile" than ever before. In previous years of amateur radio operation, people in certain

The average American is much more mobile than ever before.

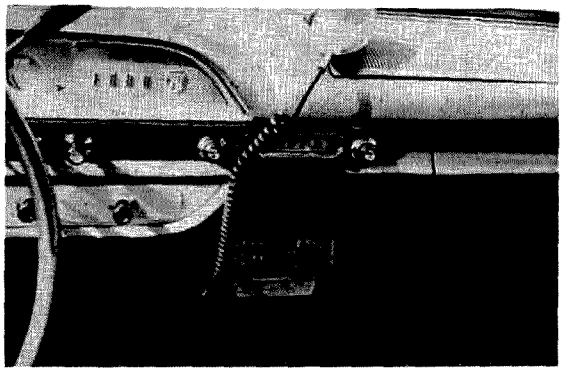
areas monitored specific frequencies. Since almost everyone was using AM, close receiving and transmitting tolerances were not required. Today, with the accuracy needed for monitoring and transmitting on specified SSB frequencies, it is becoming less and less popular to do so. Of course, there are a few frequencies that are monitored in certain areas, but these are relatively rare. Also, the congestion on the lower frequencies is increasing, thus requiring more and more power in both mobile and fixed-station equipment.

The trend is thus towards a universal fixed-frequency type of operation in cases where reliability and performance are required. This has been met by using certain specified frequencies and fixed-frequency FM equipment. The most popular of the universally accepted VHF frequencies are 52.525 and 146.94 MHz.

Operating on VHF FM

Operation of VHF FM is very much like operation on the lower frequencies, and yet it is very different. It is like AM, SSB, and even CW in that there is much ragchewing, many technical discussions, and even emergency and traffic nets. You can call your buddy, check out equipment, and handle traffic and emergency situations. It is quite unlike SSB, AM, and CW in that there is no need to retune the transmitter and receiver every time you operate; there is usually no background noise whenever the frequency is not in use (almost every piece of commercial FM gear has a noise-stopping squelch); high power is not needed for general use; and the frequency is almost constantly monitored.

Although the sudden popularity of FM and the increasing availability of specially designed gear threaten to change the picture, the equipment used by the average FM'er has typically been obsolete commercial equipment previously used by police, fire, taxi, utility, and other groups. This equipment has a power *output* of from a few milliwatts to nearly 100 watts, and a frequency selection of from one to four crystal-controlled channels. The design of the equipment is excellent. The receivers often have sensitivity figures of 0.5 μV (for 20 dB of noise quieting) or better. Operation of the equipment is quite simple, for it was originally designed to be used by nontechnical people in business or emergency situations. The controls usually consist of an on-off-volume control, a squelch control, and a push-to-talk microphone.



Many amateurs operate using "wideband" or ±15 kHz deviation. Some amateurs in certain areas are gradually shifting to "narrowband" or ±5 kHz deviation. This poses no real difficult problems, for narrowband signals can be received on wideband equipment (with an apparent loss of audio volumeand subsequent decrease in signal-to-noise ratio). Wideband signals can rarely be received on narrowband equipment without adjustment of the transmitting or receiving equipment, however.

Almost every metropolitan area now has at least one repeater system which will pick up and rebroadcast signals. In most cases, the input of these repeaters is 146.34 MHz and the output is 146.94 MHz. But in areas of extreme spectrum congestion, other frequency pairs are used.

The range of units (without using a repeater) varies with terrain and power output, as well as the type of antenna used. It has been my experience that the average unit now in use by the amateur FM'er (10W

output with a quarter-wavelength whip) has about a 15-mile range of communication.

FM equipment is generally reliable, and when it does become necessary to either repair or service, it is relatively easy to work on. Many units use common tube types in both the receiving and transmitting portions, thus eliminating a parts scarcity problem. Most units are divided into three distinctive portions: transmitter, receiver, and power supply, with interconnecting cables. These "strips" are often interchangable between units, from base station to mobile and from mobile to base station. Trunk mount units are usually "wife approved," for the control

head and speaker take up very little room in the car. However, there is very little difference in performance of trunk mount and dash mount units of the same type.

Acquisition of Equipment

The old Bugs Bunny cartoons used to start with Elmer Fudd reading a recipe for rabbit stew. He would quote the first instruction as "First, catch a wabbit." Well, the first instruction in the recipe for good amateur FM'ing is to first catch the unit.

Local sources of equipment vary. The best place to start is another amateur who is already active on VHF FM. Many FM'ers keep spare units around for trading and helping out newcomers. If you don't know any active FM'er in your neighborhood, then you will have to start looking elsewhere. In some localities the police and fire forces are possible sources. However, many departments either trade in older equipment on newer models, or they sell the units to the members of the department for monitor receivers and for auxiliary squad work.

Another possible source is taxi companies. The two-way radio is the life-blood of the taxi driver, so most cars are usually equipped. Herein problems also lurk. Many taxi companies trade in older units or sell them to the individual drivers. The units sold to the drivers often get resold to other

Many taxi companies trade in older units or sell them to individual drivers; but the units often get passed along more than once, and they come out the worst for wear in the shuffle.

drivers and so on until the unit is either so old or so beat up that it is good only for a boat anchor.

The modern railroader is quite dependent upon communications, so FM gear is found around rail yards. Railroading is hard business, and the equipment often sees rough service. However, many amateurs have been able to obtain obsolete equipment from railroads. If there is a repair center in your area, check with the purchasing agent there. If not, talk with someone who works for the railroad and find out who takes care of the radios in your locality.

Sometimes two-way radio repair shops are subcontractors to the major manufacturers and some even buy and sell two-way equipment. However, many of these shops

have a market for monitor receivers, system spares, and the like, and do not like to dispose of any extra pieces of equipment at low prices. There is always a chance, though, and even if the personnel do not have any units to dispose of, they often have information as to where such units can be obtained.

Utility companies usually buy equipment from the two-way manufacturers on an outright basis and seldom trade in older equipment. Often entire fleets of equipment are retired at the same time. Some companies will sell one or two units at a time while others will only sell in lots of 5, 10, 15 or more units. In these cases it is necessary for a group or club to purchase the units in order to meet the minimum purchase requirements. Of course, some utility companies have been known to give the units to a club for distribution to the membership – but such cases are the exception.

It is possible to purchase either portions of units or complete systems from companies who specialize in the surplus FM

market. These may be found by looking through the pages of this issue of 73. However, the prices are usually higher than would be paid if obtained locally. One advantage of dealing with a surplus house is that you have some recourse if you're not happy with your purchase within a reasonable period. Several of the surplus FM suppliers offer money-back equipment guarantees. Also, these companies often have a supply of schematics and other information on the equipment.

If you have a selection, always pick a mobile with a transistorized power supply over a vibrator (and a vibrator over a dynamotor, if in the same power output class). Always remember that power output is the measure of FM gear, not power input as in other equipment. If the unit is intended for fixed-station use, pick out the highest powered unit in best condition. If a choice is available between several units pick the newest type.

General Conversion Techniques

The first step in conversion is to determine the frequency range of your unit. If the source is known, it is a simple matter to check the operating frequency. If the source is not known, a look at the final tank will usually give a clue. Of course, the major manufacturers have a definite system of marking the frequency ranges of the equipment.

The first step in the actual conversion is to acquire a set of crystals on the proper frequency. This is best accomplished by ordering commercial grade crystals from a crystal company that typically supplies crystals to the two-way industry. I highly recommend International Crystal for several reasons: They can supply crystals of the correct cut and frequency for multiplication when given the manufacturer of the equipment and the manufacturer's crystal type; International guarantees crystals for correct operation; and they give excellent service in terms of turnaround time and warranty replacement. Regardless of the source of the crystals, it is important that they are of the correct cut. If the crystal was not designed for the oscillator circuit used in the equipment, it may not "pull" onto the correct frequency if it oscillates at all.

The next step is getting the heater strings on the correct voltage. If the unit is to be used as a base station with an external ac supply this step is unnecessary, for the correct heater voltage can be supplied from the ac supply.

Many 6V units have the heater strings divided into two 6V sections with approxi-

mately the same current requirements for each section. If this is the case, conversion to 12V involves merely lifting the ground side (if any) on one half of the heater strings and forming a series–parallel arrangement. It is necessary, however, to retain a balance in current requirements. That is, do not put a section requiring 5A of heater current in series with a section requiring 6.5A, etc. A small difference can be tolerated, but the better the match, the better the performance. In units where the "strings" do not exist, it is necessary to calculate the heater current requirements and then develop the necessary series–parallel arrangement.

The power supply is the next area of conversion. Fortunately, most transistorized power supplies are found in either 12V only or 6/12V combination units. Thus, I will not attempt to cover them here. Dynamotor units may or may not prove to be difficult to convert from 6 to 12V operation. The cheapest method is to replace the dynamotor with a 12V surplus unit. The DM-35 works very well in higher powered units (50–60W), and other units may be used for lower powered equipment.

The receiver power supply is almost always a vibrator supply, even in dynamotor units. The simplest modification for this supply is to pick up 6V across one of the filament strings. A 2W dropping resistor of 20–47Ω will have to be put in series with the vibrator coil if the vibrator itself is driven directly from 12V.

Vibrator units are generally of two types: Lower powered units (<15W) use a single transformer to provide voltage for both receiver and transmitter B+ lines. Higher powered units use two transformers, one for low B+ and one for high B+. In the case of the single transformer unit, the power supply may be connected across the lower leg of the heater string. In this case, allow for the current required by the power supply when setting up the heater strings or place a resistor of the correct size across the other heater string. In the case of two transformers, each one may be placed across separate heater strings. Make sure that the circuitry formerly grounded goes to the 6V point in the section which is connected

across the "high" heater string (the string which is not grounded).

The rectifiers used in older FM equipment are usually of the selenium type. If higher voltage is required, or if any one of the rectifiers is defective, replace the entire rectifier with the silicon type. This usually results in higher transmitter output and lower power supply heating.

Low-band conversions. Units which were originally designed for the 25–30 MHz range will, of course, work on 10 meters without any modifications. The only thing which needs to be done is to put in the necessary crystals and keep the deviation below the maximum allowed by the FCC. Units designed for the 30–40 MHz range will also usually work on 10 meters without modification. If the receiver will not tune down to 29 MHz, it is usually necessary to place small capacitors (a few picofarads will usually do) across the coils in the rf section. The transmitter final grid and tank coils may be slightly squeezed together to lower the frequency.

The transmitter final grid and tank coils may be slightly squeezed together to lower the frequency.

Use of the 30–40 MHz units on 6 meters sometimes requires a substantial amount of modification. Fortunately, only the rf and first mixer sections need modification in the receiver. These coils must be reduced by either removing turns or decreasing the capacity across the coils. A grid dip oscillator is a must. The entire transmitter section must be modified. Each coil must be reduced in size until it will tune to the correct frequency.

The 40–50 MHz units can be used on 52.525 MHz without modification. All that is required is the proper crystals. If, for some reason, the unit will not tune up to 52 MHz, it may be necessary to reduce the capacity across the receiver rf coils and slightly spread the turns of the final tank coil to bring them within the tuning range.

High-band conversions. Units in the 144–170 MHz range will usually tune up on 146.94 MHz without modification. Units that require modification can usually be brought within range in the following manner: The receiver rf coils may be padded within range by putting small Mylar capacitors of 2–5 pF across each section. The receiver oscillator coil may require as much as 20 pF across it. (Try for proper operation without this capacitor before adding it.)

The only transmitter stages usually requiring modification are the driver and final sections. The driver may be brought within range by either squeezing together the turns of the coil (if a coil is used) or by the addition of approximately 5 pF across the tuning capacitor (if parallel lines are used). In the cases where there is not enough capacity in the final tank circuit or where adjustable plates do not exist, it is necessary to add capacitance here also. The simplest

manner is to make a capacitor from about 3 in. of RG-58/U coax. This coax is attached with the shield side to one line and the center to the other. The coax may be trimmed about ¼ in. at a time until the final tank is resonant with the tuning slider about ¼ in. from the end.

General tuning instructions. For the most part, the FM unit is tuned in each stage for maximum output. Most equipment has either a central metering point or a test jack for each stage. In all cases a VOM may be used as a visual indication. Normally a 0–3V scale is sufficient. The Motorola units may be measured with either a VOM or a 50 μA meter. Generally, the only exception to the "maximum output" rule is the discriminator frequency, which is adjusted for a zero reading.

The receiver should be tuned starting with the meter at the second limiter test point. As the tuning progresses, it will become necessary to first reduce the signal input to the receiver and then to switch to the first limiter test point. As the second limiter approaches saturation, the reading will begin to decrease, thus giving a false reading. That is why it is necessary to reduce the signal input. The same thing holds true for the first limiter, but it does not go into saturation as easy as the second limiter and is therefore a better indication at higher signal levels.

When starting from scratch it is usually necessary to begin receiver tuning with the low i-f stage. In almost every Motorola FM unit this stage is at 455 kHz. The low i-f coils are adjusted for maximum reading at the second limiter test point (make sure to keep the signal level low enough to prevent saturation). At this time also adjust the discriminator secondary for zero reading at the discriminator test point.

The next stage to be tuned is the high i-f stage. This stage may be first tuned by injecting a signal at the i-f and adjusting for maximum reading at the second limiter test point. These adjustments may be "touched up" when the carrier frequency is being received.

The rf stages can usually be adjusted by inserting a signal at the antenna jack at a

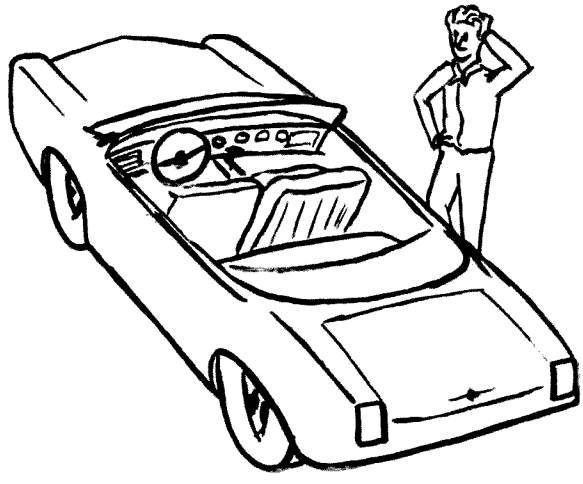
fairly high level and adjusting the coils for maximum reading at either the second limiter or first limiter test point (taking care not to saturate the stage being measured). In cases where a signal cannot be forced through from the antenna jack, it is necessary to use an injection probe of some type and start at the final rf stage and work towards the antenna.

The carrier frequency may be adjusted by metering the discriminator test point and adjusting the crystal warp capacitor or coil until a zero reading is obtained.

The first step in tuning the transmitter is to put the high–low switch located near the final amplifier section in the low position. Or, if the unit does not have such a switch, disconnect the plate connections to the final amplifier tube. This is to protect the final from damage from prolonged periods of tuneup.

Actual tuning begins with the oscillator section and works toward the final. Each stage is tuned for maximum output. A metering point is usually provided at each stage. If the unit has been modified, especially if modified from 30–40 MHz to 6 meters, it will be necessary to check the output frequency from each multiplier stage. After every stage (except the final and driver) has been tuned, replace the final tube if it was removed. Tune the driver, final grid, and final plate circuits for maximum output. Next, go back through the unit and touch up the various stages.



Antennas

The vast majority of FM operation is with vertically polarized antennas. These range from the simple quarter-wave whip to corner reflectors and yagis. The most popular mobile antenna for both 10 and 6 meter FM activity is the stainless steel whip with spring base. Next in popularity are the shortened antennas made by Antenna Specialists Company and others. The latter type may be mounted in the center of the roof or on the rear deck for better isotropic radiation.

Three types of antennas enjoy popularity with FM amateurs operating on 2 meters. They are the quarter-wave whip, the coaxial antenna, and the 5/8-wave, 3 dB gain antenna manufactured by Antenna Specialists and others. The quarter-wave whip can usually be purchased for under $5. The coaxial antenna can be purchased for around $20. The 3 dB gain antennas cost about $25, but they will effectively double the output power.

Base station antennas are also vertically polarized, and come in various sizes and shapes. The antenna generally in use on 10 and 6 meters is the groundplane, with the coaxial collinear antenna running a distant second. Both these antennas may be either purchased or constructed by the amateur.

In general, the following can be stated about VHF FM antennas: In mobile installations the best place for the antenna is the center of the roof. The next place is the rear

In mobile installations the best place for the antenna is the center of the roof.

deck or trunk lid; next comes the fender, and finally a bumper mount. In base stations, the rule is the higher the better while keeping line losses down. Remember that even the best coax has a great deal of loss at 2 meters and higher. If possible, use a very good grade of foam coax. Of course there are lines available with extremely low losses, but these are quite expensive and extremely hard to work with.

Glossary

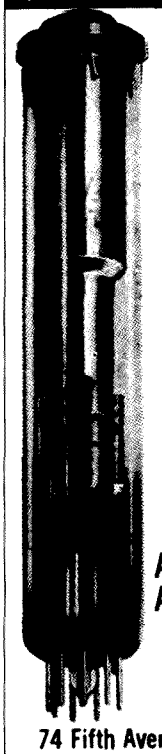
Whenever an amateur first starts out he must learn the jargon used on the bands. The same is true when starting out on VHF FM. As an aid, twenty of the more common terms and their usual meanings are listed below.

Channel Guard: A registered trademark of General Electric for a system of *continuous tone squelch.*

Coffin units: FM units manufactured in the late 1940s and early 1950s such as the Motorola 30D which consisted of separate receiver and transmitter units housed in cabinets with rounded tops which resembled coffins.

Control heads: The small box-like unit containing the off-on-volume control, squelch control, and microphone connections of a trunk-mounted mobile unit. The control head connects to the unit via a multiconductor cable.

Continuous tone squelch (CTS): A system wherein a low, subaudible tone is transmitted continuously with the voice transmission. This tone activates a reed in the receiver which, in turn, allows the squelch to operate. If the tone is not present, the receiver remains muted. This system allows only the desired stations (those with the correct tone frequency) to be received. Provision is normally made to use either conventional squelch or an unsquelched monitor position.



Deviation: The amount the modulated carrier varies from the center frequency. During half of the modulating cycle the deviation is positive and during the other half the deviation is negative. Commercial standards now call for ±5 kHz (narrowband). Most amateur operation is ±15 kHz (wideband).

Discriminators: The discriminator serves to convert the FM signal to AM and then demodulate the AM signal into audio. It is analogous to the diode detector in AM gear and the product detector in SSB gear.

High band: The slang term applied to the commercial band from 148 to 172 MHz.

IDC (Instantaneous Deviation Control): Motorola tradename for the potentiometer which acts as an "audio gain" which in turn controls the level of peak deviation.

Why does GBC sell more replacement vidicons than all other suppliers combined?

Because GBC offers top quality, fully guaranteed, factory sealed vidicons for less than half the price you'd have to pay anywhere else!

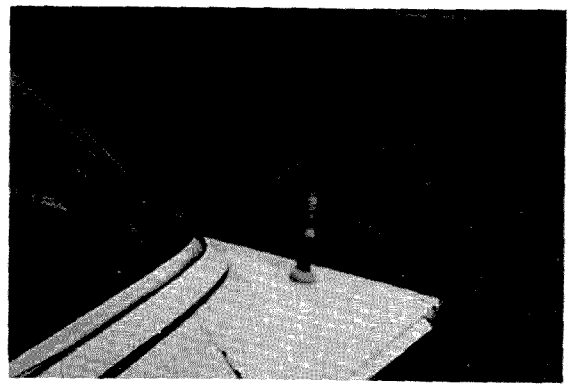
Limiter: A circuit i-f which saturates with a fairly low incoming signal, keeping the audio output from the discriminator at a constant level (similar to AVC in an AM unit). This circuit is needed because the audio output from a discriminator is directly proportional to the signal input, thereby varying with any change in signal level.

Low Band: The commercial band from 30 to 50 MHz.

Motrac: A registered trademark of Motorola for its series of mobile equipment utilizing transistorized receivers and hybrid transmitters.

Permakay: A Motorola trademark for its line of selective i-f filters. These are of two types, wideband (marked with a type number ending with the letter "W") and narrowband (marked with a type number ending with the letter "S").



Pre-Prog: Slang term usually applied to General Electric units manufactured before the "Progress Line." Often this term is used to apply to units immediately preceding the Progress Line which are similar in appearance.

Private Line: The registered trademark for Motorola's version of CTS.

Single tone: The use of a high-pitched tone for control of remotely situated functions. This differs from CTS in that the tone lasts for only a short period of time. These circuits are often used in amateur repeater applications to restrict unauthorized use of the repeater and to reduce intermodulation effects.

Progress Line: A General Electric trademark for its pretransistor line of units. These units normally have vibrator power supplies. Newer types, with transistorized power supplies, are called "TPL."

TPL (Transistorized Progress Line): A trademark of General Electric used for their line of equipment utilizing transistorized receivers and tube type transmitters. The rear mount versions of this unit have the majority of the receiving circuitry located in the control head.

Twin V: A registered trademark of Motorola originally applied to mobile units capable of operation from 6 or 12V sources.

Warp: The pulling of the operating frequency by either inductance or capacitance changes being introduced in the oscillator or i-f circuit. This technique is also called "rubbering."

SURPLUS CATALOG

A few years ago the word "surplus" was almost synonymous with military. But not today. The day of the government being the only big spender is over forever. And surplus is a natural byproduct in a world of heavy spending and innovative, advancing technologies. The heavy dollar volume pouring out of the computer industry, the concentrated spending of industry for better communications, the necessary cyclic improvement in military systems development—all contribute to the new world of Surplus.

As you look over the ads and articles in this issue of 73, you will see how the surplus field has changed. The amateur's legacy is still the obsolete AN/GRCs and such of the government. But it also includes the myriads of integrated circuit and semiconductor assemblies and components that have been replaced by the computer industry's bid for smaller, more reliable counterparts.

Contributing also to the surplus market was a decision by the FCC to make certain restrictions to commercial two-way radio users that would disallow use of all the older, tried-and-true radio transmitter–receiver units. As established radio users reluctantly parted company with their old wideband mobile units and base stations, the surplus outlets began to bulge with bargains. Since the amateur bands were not affected by the FCC ruling, the hams made excellent targets for the still-quite-usable gear.

All this has worked to the advantage of you and me, the amateurs. We can buy *good* gear—extremely well designed, well built, rugged, and field-tested—for *peanuts!* Whether your mode is FM, AM, VHF, or HF, SSB or CW, there should be a lot of available items you'll want. Just remember . . . the surplus issue comes out but once a year. If you muff this opportunity to browse the surplus catalog section, your second chance will be a long time coming.

Caveat Emptor?

Price—$2 per 25 words for non-commercial ads; $10 per 25 words for business ventures. No display ads or agency discount. Include your check with order. Deadline for ads is the 1st of the month two months prior to publication. For example: January 1st is the deadline for the March issue which will be mailed on the 10th of February. Type copy. Phrase and punctuate exactly as you wish it to appear. No all-capital ads. We will be the judge of suitability of ads. Our responsibility for errors extends only to printing a correct ad in a later issue. We cannot check into each advertiser, so Caveat Emptor . . .

DX

I am planning to make several trips between now and 1972 to rare DX locations in Europe and Mediterranean areas. I would like to receive a few QSL cards from U.S. DXers stating the five rarest prefixes in decending order of importance. Underline the particular prefix(es) *you* need. When trips are planned, an itinerary will be sent to each respondee. Do not list any "U.s." Vandegrift, MATCOM, LSMO, APO, NY 09052.

Hugh Vandegrift DL4VA/WA4WME

Christian Ham Fellowship

The Christian Ham Fellowship is one of the newest of the many ham organizations among licensed hams in the country today. This new organization now has over 300 members and an explanation of the organization for those hams who might be interested is therefore given in this letter.

The purpose of the organization is to promote Christian fellowship among those hams who are Christians. To a born again Christian this is a vital need and privilege. A Christian Ham Callbook has been published and is available for a mere dollar donation to cover mailing and printing.

The organization also is active in gospel tract mailings, and many of the members have a gospel verse or two on their QSL card as their testimony. Anyone wishing to join the organization and simply believes that Jesus Christ is Lord and Savior is welcome to write in for a free data card on the organization. This data card is then filled out and their name is listed in the new issue of the Christian Ham Callbook. The main reasons for the organization's existence is to offer Christian fellowship among Christian hams and to learn how a Christian ham can be a witness for Christ to other hams.

Box 218
Holland MI

QRP

With great pleasure, we wish to report the results to date of a number of QRP experiments, conducted by W7BVV, Bill Gibson, Salem, Oregon, and myself. Path length was computed to be 1650 miles, and frequency of operation is 28.760 MHz.

Date	Power	Mode	Station wrkd/hrd
12/29/69	2.5 μW	CW	W7BVV
01/04/70	2.5 μW	CW	W7BVV
01/04/70	25.0 μW	AM	W7BVV
01/05/70	2.5 μW	CW	W7BVV
01/05/70	25.0 μW	CW	W7BVV

Our computations and measurements imply that the minimum power required to maintain a CW circuit over the path between W7BVV and this station is on the order of 1μW. We continue to work towards this goal. We have worked many other stations throughout the US and Canada with power outputs down to 100μW AM phone. In addition, we wish to report that we worked CE7DW, Puerto Mont, Chile, 600 miles south of Santiago, with 250 mW AM phone, and received a report of 5 x 7.

The Cover

The cover this month shows what may well be one of the nation's highest repeater sites. Atop 10,700 ft Sandia Crest in New Mexico, the Sandia Crest repeater, WA5JDZ, provides coverage from Santa Fe to Socorro and interlinks with two other repeaters, WA5DMQ and WA5KUI.

Amateur Radio News Page

FCC ASKS FOR LICENSE FEE INCREASE

An increase in fees for licenses, applications and other services, totaling $20 million has been proposed by the Federal Communications Commission. In a notice of proposed rulemaking (Docket 18802) the Commission asked for comments on a fee schedule that would raise approximately $24.5 million dollars – the amount of the Commission's 1971 budget request. (Under present schedules, fees bring in about $4.5 million.)

In making its proposals, the Commission said that the Bureau of the Budget had urged higher fees schedules and pointed out, in addition, that the House Appropriations Subcommittee had stated that fees should be adjusted to assure that FCC activities would be "more nearly self-sustaining." The Committee had asked for a report on action in this respect by the time of 1971 budget hearings.

Fee increases are proposed for the amateur service, for broadcasting, common carrier, and other safety and special radio services. CATV and equipment testing and approval areas which presently are not subject to fees, are included in the proposed schedule.

Fees in the broadcast services would be substantially higher and would be based on market location, type of application filing service, hours of operation,

Foreign experience counts as Extra Class credit

Requirements for holding amateur Extra license have been broadened to recognize the operating experience required under a foreign amateur license, in an amendment to the rules adopted by the Commission, effective March 23, 1970.

The Commission action, amending Sections 97.51(a) and 97.9(a)(1) of the rules, makes an amateur Extra class licensee who was first licensed at least 25 years earlier by a foreign government, eligible for a two-letter call sign (a call sign having two letters following the numeral, such as W1AA), and gives an Extra applicant credit for foreign operating experience toward the two-year waiting period for the license.

Present rules provide for issuance of a two-letter call sign to an Extra licensee first licensed by the Commission at least 25 years prior to the date of his application, but do not recognize a license issued by a foreign government for the same period of time. Existing rules require that an applicant for the Extra license must have held a Commission-issued amateur license of other than Novice or Technician for at least two years, and do not now give credit for prior holding of a license issued by a foreign government. The Commission stated that the purpose of the present two-year rule is to help assure that Extra applicants have acquired practical operating experience for a reasonable time at a Conditional class level or above, but that one effect of the rule has been to deny recognition of operating experience acquired under amateur licenses from other countries.

Three parties submitted opposing comments stating that there are not enough two-letter call signs available to satisfy all the amateurs who may request them, and that the examination standards of foreign countries are lower than those of the United States. The Commission rejected both contentions, finding the number of two-letter call signs available more than adequate, and determining that the amateur standards of foreign governments are not relevant, since the licensee in each case must pass a Commission-administered amateur examination.

SAROC DRAWS RECORD CROWD

by K6MVH

Several thousand amateurs surprised Las Vegas townspeople (who have learned to accept the unusual) by showing up *en masse* for the annual SAROC funfest and third annual FM convention. The turnout this year exceeded that of all previous meetings in spite of the fact that it was held in a new hotel (the Stardust instead of the conventional Sahara), and a record number of rooms were occupied by convention attendees.

Highlighting the convention were daily "cocktail parties" sponsored by Ham Radio, Galaxy, and Swan. It was fun to relax and watch all the old conservatives let their hair down and sing along with Leo Meyerson, who kept the liquid and the music flowing.

The FM portion of the convention was a bit of a letdown in that fewer repeater people attended than in previous years. The fun was marred even further by a couple of hard cases who got out of hand and gave the hotel management a hard time by playing radio with their handie-talkies a little too near the hard-and-fast action of the casinos.

The one element that tended to make the whole affair worthwhile was the "hospitality" suites, one for the FM'ers

and authorized power. In addition to increases in current fees, new fees are proposed for grants of construction permits, assignments and transfers, pay-TV authorizations and various other types of applications. Ham fees would be more than double the present rate, the FCC said.

Because of the high number of licenses in the Safety and Special Radio Service, the Commission said it was impracticable to establish separate filing and license fees. Increases are proposed, however, in single fees. Safety, local government, emergency, and closed-circuit educational TV are among services that are not now required to pay fees and which will continue to be exempt. But ham license fees would be hiked to more than double the present rate, the Commission said.

The Commission first adopted a schedule of application fees in 1963 with the initial fee schedule taking effect on March 14, 1964. The action was upheld in a court test in 1964.

Comments on the rulemaking are due on or before *April 20, 1970*, with reply comments due May 11, 1970.

DX'ERS CONGREGATE IN FRESNO

by A. F. Iverson WA6ZCQ

The big guns from W6-land met in conclave during the weekend of February 1 at the Del Webb Towne House in Fresno, took a good hard look at those they have been in mortal combat with during the preceding year, and decided that they weren't such bad fellows after all. All in all it was a tremendous turnout; 225 people showed up and most took rooms at the hotel. It was a cold, dry and foggy day in Fresno, but with all the activities on the program and especially the "happy hour" just before the dinner drove out all thoughts except having a good time. The talks, the slides, and the fine comradeship expressed between each other – coupled with an exceptionally good dinner – made the whole thing a big success.

Congratulations to the officers of the Northern and Southern California DX clubs, and especially Frank Cuevas W6AOA, who spent many hours putting the program together and securing Bill Rohrer W7ZFY (Heard Island) as the main guest speaker.

As a footnote we would like to see other ham groups have get-togethers such as this to improve their personal relationship and then to read about it in the various publications around the country.

VHF FM/AM HAMS ASSIST IN OKLAHOMA INOCULATION PROGRAM

by WA5JGU

Bob Cunningham, the Oklahoma City Civil Defense Radio Officer, requested amateur assistance for the Rubella inoculation drive Sunday, February 1.

20 to 25 clinics were set up in Oklahoma County. Mobiles, 6 meter AM and 2 meter FM stations were set up at clinics to coordinate activities. The VHF club and the FM repeater group covered the entire county.

WA5HWN and K5SKA were net control on 50.50 MHz. W5GGB, the Explorer Scout Post 5 station, served as net control for FM activity on 146.94, and another for MARS enthusiasts. Thanks to Tom K7TDQ, Squeak K7RBM, and a few other local FM ops, the FM suite was kept open on an almost continuous basis, and it was kept fully stocked with all the condiments one comes to expect from such places.

A considerable amount of praise is due Leonard Normad for the tremendous amount of work he puts out each year to make SAROC a success. And all indications are that he is already hard at work planning the next big shindig, nearly a full year away.

QSL Cards for Belgian Stations

The UBA asks all IARU member societies that QSL cards for Belgium be sent to the only official QSL bureau: UBA, QSL Bureau, Post Box 634, Brussels 1. The UBA has asked the editor of the US Callbook that this address be reinstated immediately in future editions. Its omission follows the action of a small private group of Belgian amateurs. UBA asks that all member societies of the IARU publish in their journals the correct address of the UBA QSL bureau.

From "IARU Region 1 News":

Ham radio in Roumania

In Roumania, amateur radio is apparently under the control of the national countil for physical education and sport, an organization supported by the government. There is a council of some 40 members, mainly from around the Bucharest area but the administration is mainly conducted by an executive bureau of eleven persons. The president is also the minister responsible for pots and telecommunications.

A paid general secretary YO3JP, together with a secretariat, is responsible for a central office. Roumania is split up into 40 administrative countries, and each country has a paid administrator who is the secretary of the radio club in that area.

Three classes of license exist in Roumania. The Novice class permits operation on the 3.5 and 7 MHz bands, with a maximum licensed power of 25 watts, and on the 28 MHz band with a maximum licensed power of 5 watts. Normal class licensees are allowed to use 100 watts on the 3.5–28 MHz bands with all normal modes of emission and 25 watts on 2 meters and other VHF bands.

With the submission of information on the results obtained, it is possible to obtain an Advanced Class license, which permits the use of 400 watts input power. Some 35 operators apparently have these facilities. The address of the Central Radio Club is Box 1395, Bucharest 5, Roumania.

Reciprocal Proliferations:
WA2's short-call try backfires...

DXers have been startled recently by the appearance of some new and strange call letters on the bands. This is going to do nothing but get worse. Reciprocation has hit the Caribbean heavily and it is now possible to obtain an operating permit in virtually every one of the islands if you have along your FCC license and proof of citizenship.

Sam Laine W2BKU arrived in Antigua shortly after the new regulations went into effect and applied for a license. Since he was the first one to get the new type of license they offered him VP2AA1. Sam threw up his hands in horror ... imagine trying to get an unusual call sign like that through the QRM! Okay, says the Communications Director, if you don't like that we can use your initials. That sounded better and the license was duly issued. When Sam opened it he found that he had VP2AASL. He is not at all sure that this is an improvement over VP2AA1.

The same day Bill Williams WA2GQT applied for a license on Antigua and received VP2AAMW, another mouthful.

The French have decided to permit reciprocation in their "departments." This means that the old rule that we could get a license to operate in France, but not in other French possessions has been changed and now the way is clear for us to hit all those juicy and little used areas such as FL8, FO8, FK8, FP8, FM7, FG7, FS7, and even FY7.

ARRL Handbook

The 1970 edition of the ARRL's "Radio Amateur's Handbook" represents a definite step forward for the League, which has been having trouble in the past keeping the book apace with the rapidly expanding and ever-changing technologies that move and advance the hobby of ham radio. Numerous updated construction projects are included, among which are power supplies from 3V to 3 kV, solid-state receivers and transmitters, plus several new VHF and UHF converters. Two new linears are described in the transmitting chapter, and the UHF/VHF chapters have been blessed with a variety of new projects.

For the first time in the history of the Handbook, a complete chapter has been devoted to VHF FM. Though just a smidgen more than three pages are devoted to this phase of the hobby, the amateur FM activity in the U.S. is surprisingly well covered. Since the material was prepared by a knowledgeable FM'er (W6GDO), I suspect that the two or three technical errors in the FM section were edited in by Doug DeMaw, the league principal responsible for publication of the Handbook. This edition contains 710 pages, including catalog section and index. There are over 1300 illustrations, many of which have been revised, and an inordinately large number of tube-base diagrams. Price is $4.50 in the United States and Possessions, $5.00 in Canada, and $6.00 elsewhere. As always, it is also available in a hard-covered clothbound edition.

Licensee "Hamworthiness" Questioned by FCC

Applications by John A. Abernethy, licensee of Amateur radio station K4OKA, Hickory, North Carolina, for renewal of General class amateur radio license and for an Advanced amateur radio license have been set for hearing by the Commission.

The Commission said there was a

BIRMINGHAMFEST
by W4FKG

The Birminghamfest this year will be on May 3 at the Armory on Oporto Avenue (just off U.S. 78 East - near Eastwood Mall). For entertainment, prizes, contests, net meetings, eyeball QSOs and fun for the entire family, plan to attend. For further information contact the Birmingham Amateur Radio Club - W4CUE Box 603, Birmingham AL 35201.

WABASH COUNTY FEST

Wabash County Amateur Radio Club's second annual Hamfest will be Sunday, May 24, 1970. Rain or Shine. Held at the Wabash County 4-H Fairgrounds. Activities will include door prizes, Bingo for the XYLs, fleamarket, technical session on the Fort Wayne VHF repeater. Tickets $1.00 at the door. For further information write Bob Mitting, 700 Centennial St., Wabash, Indiana 46992.

Long Island club makes plans for FM reoeater

A group of FM enthusiasts within the Long Island Mobile Amateur Club organized a meeting of a steering committee which would plan and implement a repeater system designed to enhance L.I. mobile and emergency communication. The meeting was held at the home of Ed Piller W2KPQ on 15 January 1970 to discuss the existing repeater situation and to generate plans for a Long Island Mobile Integrated Communication System (LIMICS).

Harry Dannals W2TUK, ARRL director (Hudson Division) appeared as an observer; also present were Fred Brunjes K2DGI, Section communication manager ARRL NYC-LI section; Jim Fahnestock W2NM, member Suffolk County Radio Club (SCRC); Art Raunch W2DID, treasurer SCRC; Van Field W2OQI, radio officer for Civil Defense and emergency coordinator of Suffolk County and member SCRC; Gerry Harrison W2ZGA, member LIMARC FM committee and SCRC; Ed Pores WA2ZBV, vice president LIMARC and member SCRC; Jules Rivman W2TD, vice president of Hudson Amateur Radio Council and member LIMARC FM committee and SCRC; and Ed Piller W2KPQ, LIMARC director, chairman LIMARC FM committee, and member SCRC.

As 146.34 and 146.76 MHz are being adopted more and more nationally as service area. Contact will be made with other surrounding repeater groups using these frequencies so as to minimize cochannel interference problems. Technical standards are to be as outlined below:

Input frequency:	146.34 MHz
Output frequency:	146.76 MHz
Output power:	10W minimum
Deviation:	15 KHz (narrowband)
Tone coding:	Initially open; may be tone-coded later
Control point:	Minimum of two and as designated
Operating Hours:	Continuous
Site location:	To be designated
Transmission cutout:	After predetermined interval
Logging:	Automatic logging

FOURTH ARIZONA QSO PARTY

The fourth Arizona QSO Party is sponsored by the Saguaro High School Amateur Radio Society. The contest begins at 2100 GMT Saturday, April 25, 1970, and ends at 2100 GMT Sunday, April 26, 1970. All bands and modes may be used. Stations may be worked twice per band, once on CW and once on phone. Arizona stations send contest number, RS(T), and county. All others send number, RS(T), and ARRL section or county. The call will be CQ Arizona or CQ Test de (call) Ariz K. Arizona

News, Reviews, Announcements

. . .Way Down in Columbus, Georgia:

The annual Columbus, Georgia hamfest will be held April 5 at the Fine Arts Building behind the Municipal Auditorium at the fairgrounds. For information, write John Laney K4BAI, 1905 Iris Drive, Columbus, Georgia 31906.

HAM HOSPITALITY

NEW YORK - Dana Polan WA2JLV offers overnight accommodations to Stateside and foreign DXers. Write to: RFD Box 44A, Putnam Valley NY 10579 or call: 914-528-3759. Richard H. Eckhouse, Jr. WA2CVL also offers overnight accommodations: 87 Lincoln Road, Amherst NY 14226.

NEW HAMPSHIRE - Jean Pierre Catala F2BO/W1 welcomes one or two U.S. or DX hams for overnight stays. Accommodations are modest (couch), but languages are no barrier if you speak English, German, or French. Address: H1 Forest Park, Durham NH 03824 or call: 603-868-2847.

ATTENTION HAMS WHO VISIT OR TAKE IN VISITORS:
How are you making out with Ham Hospitality? Tell 73 about your visits with fellow amateurs – what you did, what you saw, whom you met, the language barriers, the fun . . .Write to Hospitality Editor, 73 Magazine, Peterborough NH 03458.

Georgia QSO Party

Starts: 2000 GMT, Sat., May 9, 1970
Ends: 0200 GMT, Mon., May 11, 1970

substantial question as to the applicant's qualifications to hold an amateur operator and station license due to the nature of communications he has allegedly transmitted over his station in the past.

The issues to be determined at the hearing include: the facts concerning communications transmitted over K4OKA by Abernethy on or about November 13, 1965; January 11, April 27, October 30, November 4, 1967; January 14, 1968; October 28 and 29 and December 14 and 26, 1969; and January 1, 1970; whether the communications transmitted on those dates were consistent with the basis and purpose of the amateur radio service as outlined in section 97.1 of the rules; whether the communications were contrary to the terms and conditions specified on the applicant's license and otherwise contrary to the public interest, convenience, and necessity; whether Abernethy transmitted unidentified signals and willfully or maliciously interfered with radio communications, in violation of section 97.123 and 97.125 of the rules; and whether Abernethy possesses the requisite qualifications to be a licensee of the Commission.

From "The RaRa Rag":

Two Meter FM Group Organized

The Rochester repeater group has received the club call WA2UWQ, which will be used for a repeater. Charlie Mills K2LDU is trustee. Initially, it is planned to install a repeater at Charlie's home; later, that repeater may be installed at a remote site.

John Plumeri W2KZD is heading up a group that is hard at work installing a repeater at a Pinnacle Hill site. When both repeaters go into operation, it will put Rochester into the FM "major leagues" with two repeaters.

The repeater at Charlie's home will be set to operate on 146.28 MHz in and 146.88 MHz out. The unit on Pinnacle Hill will operate on 146.34 MHz in and 146.94 MHz out. When both are in operation, it will give Rochester local and national repeater coverage.

open input and output repeater frequencies, it was decided that it would be desirable to occupy these frequencies for repeater coverage of Long Island. W2OQI indicated that he could also use the 146.76 MHz output frequency in conjunction with his repeater at Manorville, N.Y. in the future.

Tone Coding vs Open Repeaters

Discussion of tone coding resulted in a decision to use open repeaters so that visitors from out of town could operate them. On the other hand, as chaotic conditions could arise with open repeaters in a high-population area, some simple type tone coding or whistle-on technique may be desired. This is still an open question and final resolution was shelved pending further study.

Repeater Standards

A narrowband system will be employed and the effective radiated power will be as low as possible consistent with adequate service within the designated

Somerville To Issue Special Award

by K1YUB

The Somerville Mass. Amateur Radio Club (WA1MHN) will be operating from the summit of Mt. Washington, the highest point in the northeast, on the weekend of May 23–24, 1970. Operation will be on both days from 1800–2000 GMT on the following schedule:

Band	Mode	Freq.
15	SSB	21.375
10	SSB	28.650
6	AM	50.274
2	AM	145.470
UHF	FM	449.050

Any station establishing two-way contact with WA1MHN on two different bands will be eligible for a special certificate upon receipt of a request for it and 25¢ to cover printing and mailing. Address inquiries to Civil Defense Department, Somerville MA 02145.

stations score 2 points per QSO multiplied by the number of ARRL sections worked. All others score 5 points per QSO multiplied by the number of Arizona counties worked (maximum of 14). Suggested frequencies: (CW) 3575 7075 14075 21075 28075, (phone) 3950 7275 14285 21375 28600, (novice) 3735 7175 2110. Certificates will be awarded to the top scorer in each section. When 4 or more logs are received from one section, a second place certificate will be awarded. Logs must show date and time in GMT, stations worked, bands, modes, and information exchanged. Please enclose an s.a.s.e. with your logs if you wish to receive a copy of the results. Send logs to Bob Wright, WA7ISP, 4725 N. 70th Street, Scottsdale AZ 85251 before May 25, 1970. All stations must submit a statement that all regulations have been followed and that decisions of the contest committee will be accepted as final.

Alaska okays Amateur call plates

For a mobile amateur radio station for which special registration plates are issued, the applicant, in any recognition of his service to the public, shall not pay any additional charge for special registration plates, provided he annually files his registration before November 1; in addition to the requirements of sec. 50 (a) (5) of this chapter, the station must be satisfactorily proved capable of being utilized 24 hours a day, must have a transceiver capable of operating on 75 through 10 meters, must have an antenna, and must have a power supply and wiring as a permanent part of the vehicle; the transmitting unit may be removed from the car for service or dry storage; the annual license tax is $1 for (other authorized) mobile amateur radio station vehicles, provided the annual registration is filed before November 1.

The ninth annual Georgia QSO Party is sponsored by the Columbus Amateur Radio Club, Inc. (W4CVY).

There are no time or power restrictions and contacts may be made once on phone and once on CW on each band with each station.

Exchange: QSO number, RS/RST report and QTH: County for Georgia stations; State, Province, or Country for others. (Georgia to Georgia contacts permitted.)

Scoring: Each complete contact counts 2 points. Georgia stations multiply their total QSO points by number of different states and Canadian provinces worked. DX stations may be worked for QSO points, but do not count as multipliers. Out-of-state stations will use the number of Georgia counties for their multiplier (a possible total of 159).

Awards: Certificates to the highest scoring station in each state, province, country, and Georgia county. Second and third place awards will be made in sections where additional recognition is deemed to be warranted. A plaque will be presented to the Georgia station submitting the highest overall score. Plaques will also be awarded to the highest scoring out-of-state entry, to the Georgia club with the highest aggregate score, and the highest scoring portable or mobile entry from a station operating outside his home county.

Suggested frequencies: CW: 1810, 3590, 7060, 14060, 21060, 28060. SSB: 3975, 7260, 14290, 21410, 28600. Novices: 3725, 7175, 2110.

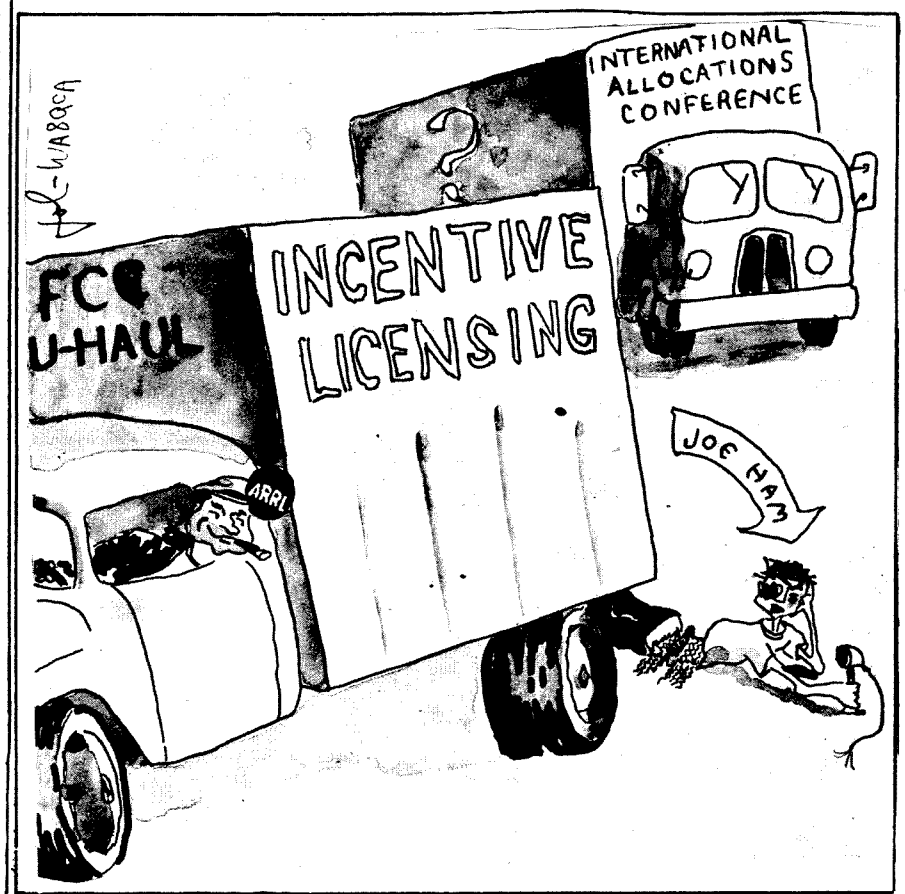
Your log should show: date and time of contact in GMT, station worked, exchange sent and received, band used, type emission, and multipliers claimed.

Include a signed declaration that all contest rules and operating regulations have been observed and mail your entry to Columbus Amateur Radio Club, Inc., Attention of John T. Laney III K4BAI, 1905 Iris Drive, Columbus GA 31906. A large self-addressed stamped envelope will be appreciated.

Entry should be postmarked no later than June 8, 1970.

HAM FEE HIKES PLANNED BY FCC

by Ken Sessions K6MVH



The FCC is holding up a glistening shaft on which it hopes to impale virtually all of the radio services. In response to a suggestion from top government officials, the Commission seeks now to increase the fees of license applicants as an attempt to balance a projected 1971 budget. Hardest hit by the move will be the broadcasters, whose lobby will doubtless resist the action with all the force it can muster. But the amateur service, with no protecting arm in Washington, will be at the mercy of the federal fund-raisers.

If the FCC has its way – which is usually the case – each amateur who wants to renew his station license will have to pay a fee of $9 – more than twice the amount now imposed. Clubs and individuals who want to apply for a special callsign will be required to pay $25 (rather than the $20 fee now levied).

The Commission's quiet announcement about the proposal (Docket 18802) said that comments were invited with regard to the planned rulemaking actions; but the kicker was that such comments were required on or before April 20 – which left nowhere near the amount of time needed to spread the word to amateurs who might want to protest the docket.

Wayne Green, publisher of 73, submitted a formal petition to the FCC requesting that the deadline for comments be extended for an additional 60 days. This request, he said, would give the major amateur journals enough time to publish pertinent facts and gather comments from interested amateurs. Green submitted his counter-petition on the same day the FCC served notification of the proposed rulemaking. No word has come from the FCC yet as to whether or not Green's postponement request was accepted.

Amateurs everywhere should make their individual voices known to the Commission. An amateur lobby would tackle this problem for us, but we are not blessed with Washington representation. It thus becomes necessary for *individuals* to protest the actions proposed on Docket 18802. Write today to the FCC, Washington, D.C. 20554. Don't plan on getting the extension. Make sure your comments are in the hands of the FCC well before the April 20 deadline. And get the word to members of your club just as fast as you can. This is an important issue, and we'll have no time to spare.

Editorials

Teletype Relay Outputs on FM Repeater Freq.

The Los Angeles area is being "served" by the WA6ITC radio repeater Teletype station. The repeater operates with an input frequency of 146.58 MHz and regenerates Teletype tones on the Los Angeles FM repeater frequency of 146.70 MHz.

According to Martin Geisler, licensee of the RTTY repeater, the transmitting and receiving equipment is situated atop the Santa Monica Mountains at an altitude of 2400 ft. As most of the local FM repeater users will sadly attest, the RTTY repeater has excellent coverage over the Los Angeles basin. Geisler says good signal reports have been received from as far south as San Diego and he has high hopes for extending the range north into Santa Barbara.

As many as 15 stations have used the RTTY repeater as a fully automatic message system. Geisler says he wants to encourage more users. Though not popular with the 100-odd people who use the W6FNO FM repeater, which shares the same output frequency, Geisler expects his system "will become popular with message handlers accepting trunk traffic from the low bands" who will find it useful for trunking the traffic locally. Since the RTTY equipment is crystal controlled, automatic operation is effected without the presence of an operator at the receiving end.

Conflict

The real story of the WA6TIC RTTY repeater is a great deal more complex and detailed than might at first seem. The output frequency was established on 146.70, which was already in use by the

With respect to the additional assessment for license fees, 73 feels that the contributions of amateur radio to society more than offset the cost of license processing. The electronics technologists in this country, for example, in large part are taken from the ranks of amateurs or former amateurs. And the communications capability of amateurs, so exploited during the war when operators were drafted *en masse*, has always added significantly to the "peace of mind" of the government. This is reinforced by the continously improving organization of amateur groups who provide an instant-readiness to serve local governments at the first hint of a need.

It seems incongruous that the amateur radio service should fall prey to the FCC's revenue drive – particularly in view of the fact that amateur radio falls within the official category of "Public Safety and Special Services," set up for the benefit and convenience of the nation.

What has ham radio meant to the United States? Well, try these for openers:

1. Every ham is a goodwill ambassador to the otherwise unreachable citizenry of foreign countries.
2. Amateur radio provides the ideal medium for getting young people interested in pursuing the vital field of electronics and related technologies.
3. Amateur operators provide the only fully organized mobile communications force that is *always* ready to be used in any disaster or emergency situation.

The points mentioned above are so important to this nation that 73 feels a strong case could be made for requiring the government to actually subsidize ham radio – furnishing the gear and paying the operators. Not that we expect that or want it. But it is difficult to see how the FCC can justify added fee assessment when, by the FCC's own admission, the real worth of the hobby is its value to the country.

ITU CONFERENCE: Who lobbies for ham radio?

by Wayne Green W2NSD/1

If the amateur shortwave allocations are to survive the next ITU frequency allocation conference in a recognizable form we need to have some basic changes made in the instructions given to the delegates – U.S. and foreign.

This sorts itself out into two projects, getting the support of the U.S. delegation and getting the support of all of the foreign delegations. Neither of these is going to be easy.

The U.S. delegation can be worked on at many levels. It is made up of representatives of the many radio-using services, a good proportion of them government run. The basic approach to changing governmental thought is to work through the mechanism set up for this: congress. Congress has considerable influence since it watches over the governmental departments with committees and it hands out the yearly allowances.

Since the only legal way for any amateur organization to approach congress is by means of a representative who is registered with congress to lobby, we have a serious problem. A tax-free organization cannot lobby ... ARRL is tax-free ... thus, unless ARRL changes its tax-free status, no employee or representative of the League can risk even talking to a senator or representative. ARRL cannot change to a tax-paying basis without radical changes in its management, so it is extremely unlikely that this will take place.

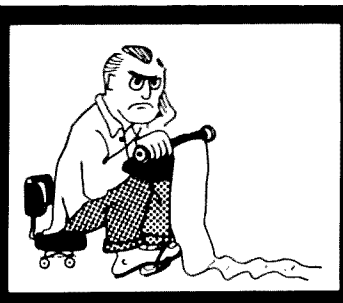
One man with the time and money probably could make a profound change in the attitude of the U.S. delegation to the ITU. It would take time, to be sure, for he would have to sit and wait to see busy senators and representatives, see top brass military, FCC commissioners, and on down the line. The end result would be that the delegates sent to Geneva would be instructed by their superiors that amateur bands are to be kept intact, even if their particular service suffers a loss. In the past we have had large quantities of lip service paid to the amateurs, but when it got down to a loss of frequencies for any service, they looked to the nearest amateur band for replacement.

Foreign delegates can be reached through high government officials. Amateur radio is of critical importance to every country for it provides one of the best ways for them to interest youngsters in a technical education. No country can keep pace or development without large numbers of electronics and communications men. Without amateur radio, how can the thousands needed be interested in turning to this field?

One man could have a profound effect on this whole situation if he had the time to see government officials and make them aware of the importance of our hobby. This is needed mostly in Africa and Asia where new nations are trying to bridge the gap into the modern world of computers and satellites. These same countries hold the critical votes at the ITU.

The amount of money needed to apply pressure at home and abroad is minuscule to any large business or club ... probably a mere $50,000 a year could make the difference between our having a healthy and expanding hobby in the future instead of a gradually emasculated hobby. ARRL has the 50G to burn, but has not the will to use it. No one else has the 50G. What do we do now?

Los Angeles area FM 2 meter repeater. As a result, when radioteletype signals are fed into the WA6ITC machine, the local FM repeater, principally a mobile relay facility with more than 100 users, is virtually forced out of service.



Even though 146.70 MHz was a "vacant" channel when the FM repeater was installed, the RTTY enthusiasts (5 in number) rallied to save the "national" RTTY channel from being usurped, and eventually had put up the RTTY repeater so the output would "capture" the local FM repeater. Perhaps the FM'ers were shortsighted in putting up the repeater on a channel recognized nationally as a radioteletype frequency. And perhaps the five RTTY men were rambunctious in their selection of an already-in-use channel for their base-to-base communications. Certainly, there are two sides to the issue. Since there is no compatibility between the two modes, the FM group has offered to put the controversy before the ARRL-affiliated Los Angeles Area Council of Amateur Radio Clubs for arbitration. If the RTTY repeater group agrees to allow the council to act as arbiter, the next few months could see a new repeater forming and a shift by either the RTTY stations or the FM crowd.

REPORTERS WANTED

Write for the 73 Amateur Radio News Page under your own byline! The News is looking for items of general interest ... hamfests coming, hamfests just happened, expeditions, emergencies, special events, anything of special interest that might have happened on any band, new records, moonbounce news, FM repeater openings, unusual club activities, whatever turns you on.

Reporters whose items are selected for publication will receive a special press card which may help them get into places closed to the general public, making the reporting of emergencies and special events a lot easier.

The deadline for all reports is the 15th of the month. Reports received earlier will get preference as there can only be room for a few last-minute items.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

How Fast Can You Work 100 Countries?

When I first put in my present station five years ago it took me a good two weeks to work 100 countries. By way of proving I'm not sure just what, I took advantage of the first weekend of the ARRL DX phone contest this year to see if I could make WTW–100 all in one weekend on 20 meters.

Feeling a bit overconfident, I started over an hour late...but, after all, it was the first night out for dinner since the baby arrived a month ago, so I didn't want to strain family relations by rushing too much. Wives have a hard enough time getting used to seeing just the back of your head on your weekend at home without starting things off badly.

South America and Africa came through fine for about three hours and then the band folded for the night. With the exception of 9N1RA and FR7ZC, none of the 33 countries contacted were particularly rare. Jinny has certainly been active from Nepal and her signal was outstanding.

When I got up the next morning the band was busy with Europeans. By afternoon I was up to 73 countries and had hopes of getting the hundred within 24 hours. Three hours later, with only three more countries added, it was obvious that this was going to take much longer than I expected. I had a leisurely dinner, watched some television, and helped mind the baby before going back to the band.

It was definitely hard going. I had worked just about everything in Europe except the hard ones such as HV, 9A, 3A, HBØ and the like. I tried not to make too many duplicate contacts, but every now and then a pileup would prove irresistible and I would plunge in for an extra VU2, CT2, UW9, or something reasonably rare. I went to bed with 87 worked and the band dead at midnight. Thirteen more shouldn't be all that hard the next day, right?

A 5:30 start netted me a few new ones, starting with my good friend Chet PJ2CC down at the Beachcomber Hotel in Curacao. By 9:00 a.m. I was up to 93, but the band was full of nothing but unrare Europeans, so I went back to bed. Pierre F2BO/W1, his wife and twin babies arrived at noon for a visit. I got back to the rig about 3 p.m. and, when the band finally opened to Africa again, worked my way up to 99. With two hours to go that shouldn't be a big problem. It was, and I snagged 6Y5AV out of a horrendous pileup with just seven minutes in the contest to go, making it 100 exactly.

My total operating time came to only 17 hours, so I had a great time without getting too tired. Some of the fellows who had been chasing DX on four or five bands, making 1500 to 2000 contacts, were pooped for fair. I made only 132 contacts. Three of the countries were new for me, but for the most part I was surprised at the lack of rare countries in the contest. Two of the three new ones were not really in the contest, but just happened to be around. The activity in Africa was extremely sparse, with less than ten stations giving the contest much effort. The band was open to Africa quite a bit, but all that I could hear were three CR6s, a couple of ELs, a couple of ZSs, and 5H3LV. North Africa didn't open up much at all, with 9H1CD complaining of sitting there hearing the Ws weakly for seven hours before he was able to make his first contact.

One thing was very obvious...the General class licensees didn't have a chance in the world of seriously getting into the contest. Only during rare high points of activity would the action spread on up to 14.275. A General might just as well forget working DX on 20 meters.

My station, for those picturing mammoth beams on top of a mountain, along with a room full of equipment, consists of a five-year-old transceiver, one of the least expensive made, a Henry linear amplifier (2K, not 4K), and a simple three-element beam up 70 ft in downtown Peterborough.

Leaky Lines vs Technicians

When the February LL column arrived I read it to a Tech and he turned livid. I knew we had a winner. Even the gentlest discussion of cheating on the Tech exams makes most Techs fighting mad, with those who cheated to get their ticket having an edge on the degree of ferocity.

The cheating that takes place is generally done in friendship, though it leaves both parties feeling guilty afterward. We had the same problem with the Conditional license and that had a

lot to do with the virtual elimination of that license class.

Cheating is a problem and it is not one that will go away if we refuse to discuss it and try and work out some reasonable solutions. It is extremely difficult to discuss because of the emotional factors. Those who were absolutely honest on their exam and code test are affronted at the suggestion that they might have been helped. Those who were helped are feeling guilty and would prefer that something else be talked about.

One solution that I have proposed in the past is a little change in the rules which would make it necessary for exams to be given by three licensed amateurs instead of one, figuring that it is a whole lot more difficult to get four people to agree to something dishonest than two.

Let's give some thought to the Tech license. The Tech license differs in two quite basic ways from the General: There is the difference in code speed, 5 wpm opposed to 13; and there is the manner of administration of the license exam, with the General having to face an FCC examiner – and the Tech, his friendly local licensed amateur.

In considering the matter of code speed, the philosophical arguments about the usefulness of code are irrelevant. The fact is that under the rules now existent you do have to learn to send and receive the Morse code at 13 wpm if you are going to get a General license.

How much of a barrier does the code present? How much of a difference between getting the General and the Tech licenses is due to the problems of learning code? Amateurs who have helped thousands to get their General license tell me that *anyone* can learn the code and pass the General exam. Some people take longer than others, of course, but apparently no one can honestly plead an inability to learn code. Once the decision is made that the code will be learned, the process takes amazingly little time, from mere days to, at worst, weeks.

On the face of it, the code would not seem to be enough of a problem to prevent anyone from getting the General license.

Which brings us to the FCC examiner. Now, I recognize that it is entirely possible to copy 15 wpm perfectly the night before the exam and still fail miserably just from the tension and panic of taking the FCC exam. I've not only seen it happen, I've experienced it myself. But eventually you do calm down enough to copy enough letters to get through the code test and you are ready for the technical exam.

The written part of the test should be about the same, whether you are with a friend or at the FCC emporium, unless you need help with the hard spots, in which case the FCC could be more difficult.

Code Requirement: Dirty Words?

Many a CB'er, SWL, and even Novice amateur has had good cause to curse the Morse code. I hope you will not turn off if I suggest that there may be a very good reason for keeping the code requirement for the amateur licenses.

Yes, I think I know all of the arguments against the code. It is an anachronism. It is a relic of the past. I agree with that, but I don't agree that that is all it is. Yes, I know that teletypewriter and radioteletype have made devastating inroads into the commercial use of code. I know that the military uses it very little any more.

One of the principal users of Morse code is the amateur, I suspect. Code is still alive in many of the ham bands–and not just the Novice bands, where the operators are limited by law to that mode of emission. There is a lot of ragchewing going on in the code-only portions of the bands, a lot of DXing, and a lot of traffic handling around the dozens and dozens of traffic nets organized by the ARRL. But even this is not a good reason in my mind for the insistence that all amateurs know the code. I figure that those who like it will develop their ability to use it, and those who don't can just go ahead and use phone. Whatever turns them on, I say.

The fellows who are using code tell me that it is fun, that they enjoy it enormously. If this is so, then I'm not sure that I can agree with those amateurs who feel that we must insist that every newcomer learn the code to get his license because if he can get a license without learning the code he will never try it. I suspect that communication by dots and dashes might just be a whole lot more popular if it weren't jammed down our throats. I am pretty sure that my own antipathy to code is a result of my having to learn it, whether I liked it or not. I resented that and reacted to it negatively. I enjoy things a lot more when I do them of my own free will.

There is a basic difference between having to pass the written technical exam and the code. I could see where the technical exam was important as an eliminating factor for those fellows who do not have enough knowledge to properly operate an amateur station. That made sense. But why code? I had no need of it if I was going to operate phone, so why force me to develop a skill, as opposed to a technical understanding? An unneeded skill, at that!

Some amateurs argue that in times of emergency code might be the only mode that could get through. Balderdash! Forty years ago, maybe. But today most of the emergency rigs are mobile phone rigs, usually sideband. And I have yet to see many cases where sideband can't get through just about as well as code. That is a very weak argument to me.

So what possible reason is there left for the excruciating and frustrating process of code-learning being part of the amateur license? And not just a part of it, but by far the most difficult part to master. The technical end is considered by most amateurs as being terribly simple. Virtually any EE college graduate can walk into an FCC office and pass the amateur General

WHEN IT COMES TO ANTENNA SYSTEMS... IS YOURS

a space problem? a budget problem? an applications problem? an installation problem? or simply a problem of where to buy?

Your one-stop solution is ANTENNAS, INC.
Exclusively specialists in radiating systems, complete systems or any component part.
Arrays—complete or in kit form, quads, yagis, dipole assemblies, verticals—fixed or mobile, towers, masts, rotors, guy and control cable, transmission line, coax relays and switches, connectors and adaptors, test gear, technical publications, corrosion resistant hardware, corrosion proofing chemicals, insulators, installation and wiring hardware, aluminum tubing and plate, wire, and much, much more.
If your requirements are for a complete system, major components, or the smallest yet important piece of hardware—

Our prices and deliveries are hard to beat . . . anywhere.

ANTENNAS, INC. can be your one-stop, single-source. Write today for our catalog . . . no charge of course.

exam with just a few hours' study of the rules. Why, when amateur radio is supposed to be a technical hobby, is it in reality a skill hobby instead? The technical end seems to fade into insignificance compared to the skill aspect.

The answer should be getting obvious now. Anything easily obtained is not treasured or appreciated. I suspect that the very difficulty of the code requirement is one of the basic reasons for the legendary ham spirit . . . the pride of being a ham. It is most definitely an accomplishment to pass this hurdle, particularly in this day when virtually no one else is using the code. This means that the code has to be learned specially for the ham ticket by *everyone*.

Show me one person, if you can, who is not proud of his ability to copy code. Sure, I know thousands of hams who haven't been using code for years, but I don't know one who doesn't swell a bit with pride when talking with nonhams over his having passed the code exam.

RM-1456

It seemed to me that one of the problems facing the Techs is their isolation from CW and that if they had more of an opportunity to use it they might be inclined to go for their General. The code, as I said before, is not difficult to learn once you make up your mind to have at it. In spite of the nice special CW band at the low end of 6 meters, the Techs have so far almost completely avoided any contamination with CW. So, even if a Tech wants to get on and try to improve his CW ability, he is frequently stuck for someone to work with. So I proposed that Techs be permitted to use all Novice bands. This petition was sent to the FCC and given the number RM-1456. Nothing further has been heard of this petition except one letter from WAØLIK in support of it. If you think the idea is a good one you might send a letter to the FCC in support.

Phone operation on 6 meters is a good hobby, I grant. So is 2 meter FM and the other pursuits of the Technician licensee, but it is a real shame for the code to stand in the way of the fun and aggravation to be had on the lower bands. I enjoy 2 meters a lot, but I would be resentful if I were forced to stay there and not permitted to get on 20 meter phone.

A Solution to the Code Problem?

Since anyone who wants to can learn the code, it seems to me that a whole lot of Techs could be encouraged to become Generals if we first of all try hard to get them to improve their code speed, and secondly make it as easy as possible for them to do this.

How do we make it easy? We can step up the code classes in our radio clubs and get every 2 and 6 meter member to scrounge around the bands looking for Techs to get in the classes. Don't forget the coffee and doughnuts after the code sessions. Further, any operators on 2 and 6 can easily spend an hour or so a week sending code practice sessions on the air.

What do you send? I suggest that you look into the commercially prepared tapes since they are perfect code and of known speed. Move up into the band where you won't drown out regular contacts and set up a schedule of code practice sessions nightly or whatever you can handle. Keep them inflexibly on schedule so you don't lose the audience that you gradually build up. WIAW isn't the only station that can send code practice, you know.

Since a great many ops depend a lot more than they should on memorizing of the license manual to pass the exam, it won't hurt at all to begin each club meeting with a short tech session to help the members better understand the theory. Understanding gets you through the exams a lot better than memory.

Is your club doing everything it can to help its members up their license grade? Is your club honestly trying to recruit new Novice and Tech members and help them? Or is it like many that I have known, run by a handful of oldtimers who discourage newcomers? Don't look to the ARRL to suddenly start a nationwide PR campaign for the hobby...decide that you and your club will swing into action in your area to get more hams and move all members up at least one license grade.

73,
. . . W2NSD ■

My February editorial with respect to the new interim regulations for Canadian amateur repeaters has brought an unexpected spurt of responses from Canadians who feel that insufficient credit for the rules was given the Canadian repeater organizations. This is a point I certainly should have brought out, and I take this opportunity to do so. The rules adopted by the DOC (Canada's FCC) were a direct result of suggestions supplied by the Toronto FM Communications Association and the Ottawa Amateur Radio Club (and perhaps others). The point that was meant to be made in the earlier editorial was that the rules were based on the Buffalo petition – which is still a fact. The Buffalo petition served as a foundation from which a new draft was formulated by Paul Hudson VE3CWA and others. The draft became the DOC interim requirements for repeaters.

My apologies to the Canadian amateurs for my neglect. And a hearty well done to them for taking an issue and getting something done about it. We U.S. amateurs could learn something from this sequence of activities and cooperative efforts, I think.

A.E. Blick VE3AHU writes:

"...note that these are interim regulations and will not become formal regulations until they have been assessed as to their worth. Incidentally, you omitted to include the first regulation, which states: 'Applications for Amateur automatic repeaters will be considered on a case-by-case basis, as in the past.' This means that such stations will not be automatically licensed providing they meet the other requirements. Also, that the DOC has already been asked to drop the requirement that only the licensee be enabled to reset the repeater and consideration be given to an automatic device such as you mention."

C.H. Harrison K2QPF writes:

"...I feel you're taking issue with the Canadian interim FM repeater regulations 3-minute timeout requirement without complete analysis. The purpose of the automatic shutdown timer required by the regulation is obvious – to disable the transmitter in case of failure in the normal operational control circuitry. This requirement is desirable, and it should require reactivation only by the licensee. Your analysis overlooks the use of a second timer circuit which is part of the operational circuitry, and set for example at 2 minutes. It would terminate the carrier as in the usual sense, and reactivate automatically when our longwinded friend finally let go of the mike. The 3-minute timer would function only as it should; to completely disable the repeater until the licensee could analyze the cause of the malfunction, make necessary repair or adjustment, and return the repeater to service. The two-timer approach meets both the usual operational interruption of the longwinded channel hogger and the necessary safeguard requirements to reliably disable a malfunctioning repeater."

* * *

Since I always have a great deal to say but very little space in which to say it, I try to cut my editorial verbiage down to the barest essentials. As a consequence, I cannot always philosophize and ramble the way I'd like. And besides, with Dave Mann's Leaky Lines, 73 has about all the philosophy it can handle in any one month. But it seems to me that it is high time for at least a teensy bit of maundering, in defense of my position and 73's after Dave Mann's comments about the chastity of Technicians in general (February, Leaky Lines).

It is first prudent to say that I am editor – not a censor. Dave Mann's editorial material does not necessarily have to coincide with my opinions to be accepted for publication. He is entitled to speak his mind freely when he writes, regardless of how much I may disagree with the statements he makes. Which is as it should be.

Last-Minute Flash!

The FCC has prepared a "proposed rule-making" set of constraints with respect to oper-

ation of repeaters on the amateur bands, and is asking for comments before May 15, 1970. The complete text of the docket is not yet available, but an FCC representative listed the major points under consideration. They include relaxed logging requirements, automatic ID at 3-minute intervals, no repeaters below 50 MHz, mandatory tone control or whistle-on activation – all of which were recommended in RM-1542, a petition submitted in December.

But the FCC has gone a bit further by recommending that no links be allowed, no more than one transmitter be activated from a single receiver, no crossband operation, and no unattended repeater operation. The implications carried by these last items are weighty indeed, and warrant the immediate attention of every repeater owner, remote control operator, and prospective repeater/remote operator. If crossband operation is disallowed, there can be no city-to-city repeater interconnects. There can be no remotely controlled amateur stations, because all radio-controlled transmitters and transceivers involve UHF portions to link signals to and from the remotely controlled equipment.

The FCC deserves credit for making the effort to get repeater operation into the rules and regulations. But repeater progress will come to a complete standstill if the crossband and multiple-output recommendations of the FCC are upheld. The May issue of 73 will carry the complete text of the FCC's recommendation along with proposed alternative actions. Whatever you do, don't fail to get the May issue to see what's happening with repeaters. And if you have comments, you will have until May 15 to get them into the FCC office. 73 also will be filing a list of comments on this docket; these, too, will be published in the May issue.

If you plan on making comments on this important docket, don't do it yet. Start thinking about what you want to say. Discuss it at your next club meeting. Make notes. But read the FCC's recommendations before you file your comments. If you're an FM'er and you fail to comment on this vital issue, you'll have no one to blame but yourself if the FCC docket gets through unscathed.

* * *

There is a fairly common myth that I am beginning to hear more and more frequently quoted as truth. Since the myth affects me (and you), it's up to someone to talk about it. I don't know where it started, but I know it is known nationally. Worded in any of a dozen ways, it goes like this: *Amateurs who are not members of the League have no right to complain about the ARRL, its workings, policies, people, tactics, or structure.*

Now, I wouldn't worry if this were merely someone's misplaced ideology. I think it began as some League member's defense of League actions. But this month you will see it cited in Leaky Lines by Dave Mann, who has a reputation for "calling 'em right."

Lest the adage get perpetuated as a verisimilitude, I will risk sounding anti-League by debunking it. Whether I agree with the ARRL or its policies is immaterial. The fact remains that what the League does, what the League decides, what the League recommends – it does so not on behalf of its membership but on behalf of *the amateur radio community as a whole.* Since every nonmember is affected by every major ARRL decision, every amateur, member or not, has the right – and the duty – to be concerned with and get involved in League affairs.

Let's take the incentive licensing thing as an example. The League originated the proposal; but did it affect only League members or did it hurt us all? And how about the current Technician spectrum gift: Does it apply only to ARRL members or will all amateurs have to comply with any FCC decision based on the proposal? And the ARRL's repeater recommendations: Will they end up as League-only rules, or will all repeater owners and operators be forced to live with them as well?

As long as the ARRL's actions affect you as an amateur, you have an obligation to know what the League is doing and when. Your responsibility is not so much to get in the League, but to make your voice heard. As a nonmember, your right is even more intrinsic than it would be if you were a member. A League member pays his dues, which serves as that individual's approval of the way the League does things. His money (in dues) is a vote of confidence for "the system." Since the member is supporting the system, he has scant right to complain when he's knifed by the system – after all, he shares responsibility for its existence.

Ah, but the nonmember is another story. *He* does not back the system. He does not approve of the system. He does not believe in the system. Who, then, has *more* right to complain about being plowed under by the system?

If anyone ever tells you that you should join the League so that you could "effect change" from the inside, don't you believe it. Hams have been trying for years without success. But it doesn't take a genius to figure out that if every dissatisfied ham dropped his membership, the ARRL would either change or drop out itself. Your most powerful voice is NOT your ARRL membership. Rather it is the absence of it.

Don't make the mistake of labeling me anti-League, because I'm not. Neither do I appreciate the power of the League, however, to speak for hams who don't believe in the ARRL. I simply believe that *all* amateurs, League members or not, should have the right to vote on issues that affect all amateurs. Doesn't that seem reasonable?

AN
EDITORIAL
by
DAVE MANN K2AGZ

Leaky Lines

1 DANIEL LANE, KINNELON NJ 07405

According to Yankee Legend, if you should encounter the ghost of Daniel Webster, he would ask just as in life, "How goes the Union, neighbor?" If there are truly shades and spirits, and I am not one to deny it, perhaps those which quickened the mortal coils of our hobby's pioneers might be asking, "How goes amateur radio, Old Man?"

Regrettably, the answer would not ring out so confidently and affirmatively as would our reply to old Dan'l. The state of amateur radio is not so sound as the state of the Union, despite irrationally optimistic claims to the contrary. Of course, all is not completely hopeless; things seldom are. But there is an air of demoralization which seems to be widespread, and this is evidence that we are disturbed and hagridden. We seem to be in an apprehensive mood, waiting for disaster to strike, from who knows what quarter. Like Tennyson's Light Brigade, there are "guns to the right of us, guns to the left of us," and we know not whence will come the volley and thunder.

Newly emerging nations eye our frequencies with covetousness. Commercial users intrude into our spectrum in blatant defiance of the assignment regulations. The communications facilities of our own armed forces create interference on the ham bands with impunity, and so does Voice of America. Municipalities devise pernicious covenants and restrictive codes, limiting or altogether prohibiting towers and antennas, and they sometimes even enact ordinances against our right to operate at all. It seems that although we are guaranteed the freedom to pursue happiness, this sometimes excludes the operation of a ham station!

In addition to all this harassment from outside sources, we are inwardly divided into sects and contending factions. After over fifty years of existence we find ourselves cloven into angry splinter groups, snarling and yammering at one another. At a time when we need desperately to be united, we are being hopelessly split asunder.

"How goes amateur radio, Old Man?"...Not so well, I'm afraid. We have witnessed dramatic changes in both the direction and character of ham radio in the past several years. This hobby started out as the sole province of the serious science-minded. It is now being contended that it has become the playtoy of entertainment seekers, just fiddling around with a novel and intriguing gewgaw. It is said that for every ham who is genuinely motivated by theoretical and technical aspects of the hobby, there are scores who possess only the most meager and sketchiest idea of what it's all about...who are capable only of plugging the rig into a wall receptacle, turning on a switch, and talking into a microphone.

This is an abominable situation, if it is true. If untrue, then it is a slander and a damnable libel. As for my own opinion, I tend to think it's untrue. There are literally thousands of amateurs deeply involved in the development of science and technology. The large laboratories at Bell Telephone, Bendix, ITT, Sperry, IBM, GE, and countless others, are engaged in a universally burgeoning program of research and scientific inquiry. And in every area of this rapid proliferation, on every level, conspicuously and meritoriously recognized for their contributions, there are radio amateurs. These people do not leave their knowledge and ingenuity outside the door to the hamshack.

Advances in the techniques of communications science, as in most other fields, have been accomplished largely by a select, determined group of innovators, far in advance of their contemporaries. A case in point: single sideband. Bell Telephone was involved in this field around the time of the first world war. Except for a tiny circle of knowledgeable hams, sideband remained practically unknown on the bands until the end of the thirties and the beginning of the forties. It did not become a practicality until after World War II. And even now, in 1970, it is not yet universally recognized as an acceptable form of communications. There are still hams who are resisting the mode and trying to shoot it down, because they view it as a newfangled fad which will never catch on. After almost four generations, imagine, single sideband is still regarded in some circles as a passing fancy, totally devoid of merit or value! Does this mean that the entire amateur community is decaying? Not at all. It simply signifies that some people resist change more tenaciously than others. It certainly does not entitle those who accept new ideas with eagerness and alacrity to feel contempt for those who do not do so.

We often hear of the impossibility of changing

human nature. While this popular cliche enjoys wide acceptance, it is only a half-truth. The human being has been in a constant state of change throughout his entire history. The changes have been slow and all but imperceptible. Yet they have occurred. There is a mighty inertia, no one can deny it, which prevents people from accepting change willingly. This is a personality characteristic, more pronounced in some than others. Even the introduction of inducements or penalties does not make it any the easier for people to accept change. In India, where there is unspeakable poverty coupled with tremendous overpopulation, the government sought a solution by offering a handsome incentive. They offered a significant monetary reward to all married men who would submit to an operation called a vasectomy. This is usually a painless and harmless procedure, requiring no hospital stay, and relatively simple. Despite the urgency of the situation and notwithstanding the great need for the money, very few men have come into the public health clinics for vasectomies. Incentives, like deterrents, are rarely successful. The death penalty, invoked for centuries in all the countries of the world as a deterrent to capital crimes, has rarely, if ever, prevented a murder!

There is slim likelihood that the entire ham population of the United States can be transformed into a community of scientifically motivated electronics specialists. We might as well demand that everybody who buys a piano must learn to tune and regulate it. Or that every driver must learn to service and repair his own automobile.

Well, what about this tendency of some amateurs to be contemptuous and disdainful toward the so-called "appliance operator?" First of all, we must expunge from our consciousness the idea that the standards of amateur radio are becoming degraded simply because some of us are not brilliant enough to homebrew our own stations. Those in the vanguard of the hobby are every bit as creative as their counterparts of yesteryear. It is merely that we have grown mightily in numbers since then, and the proportions have become altered. It is proper for hams to be made to conform to minimum standards of competence. But we must guard against the tendency to raise those standards to an unrealistic level. This road leads to the establishment of an elite caste; an aristocracy. And it's a certainty that no one, not the FCC, nor the ARRL, believes that all hams can become Extra Class operators.

In far too many circles there is a growing sentiment that a stigma attaches to anyone without an Extra Class ticket. It should be borne in mind that a licensed amateur, apart from the frequency restrictions specified by his grade, is just as good as any other amateur, whether he is an electronic genius or just a chap who is in the hobby for the sheer pleasure of it. If we fail to remember this, we are very likely to witness the loss of one of our most prized possessions; the wonderful cameraderie which has characterized amateur radio from its very beginning. And that would indeed be a tragedy.

* * * * *

As long as we are told that we are on such good terms with the countries of Latin America, through the "Good Neighbor Policy," and all the other huge spending programs that are helping to keep the ordinary people of our own land impoverished, I'd like to make a proposal.

Of course, I do not think it likely that this proposal will meet with strong approval in these countries, because I do not happen to believe we are on such good terms after all...in spite of all the fancy claims and contentions. I believe in that old saw about actions speaking louder than words. And I recall vividly the way Mr. Nixon was spat upon in South America...how the ships and property of American firms were seized...and many other manifestations of "antigringoism" in recent years. Mr. Rockefeller's recent factfinding mission was surely no exception either. It is clear that our stock is pretty low, unofficially anyway, south of the border.

Still, there appears to be a certain detectable cordiality between the hams of Latin countries and the hams of the United States. Because of this rather inconsistent ray of sunlight in the otherwise impenetrable darkness, I should like to suggest that someone try to prevail on our Latin American neighbors to stop running those ubiquitous phone patches on the low end of our 20 meter phone portion. This is probably the worst single source of QRM on our best DX band. And one of its most annoying features appears to be the constant participation of poorly modulated female voices, which frequency-modulate all over the place. When one of those gals starts delivering that rapid-fire Español, you might just as well forget about working anything within at least five kilohertz.

Since all South and Central Americans have privileges below 14.200, how about getting ITU or ARRL to make overtures to LABRE, RCV, RCP, RCB, etc., to get some sensible phone patch frequency recommendations, which will confine this troublesome annoyance to a more reasonable portion of the band.

Of course, I've noticed that about half the patches are made to the Miami area, and that rather complicates matters. I have a swell idea on that situation too, but I'm not going to dare to suggest it. I might find a line of bearded pickets, wearing fatigues, parading up and down in front of my house!

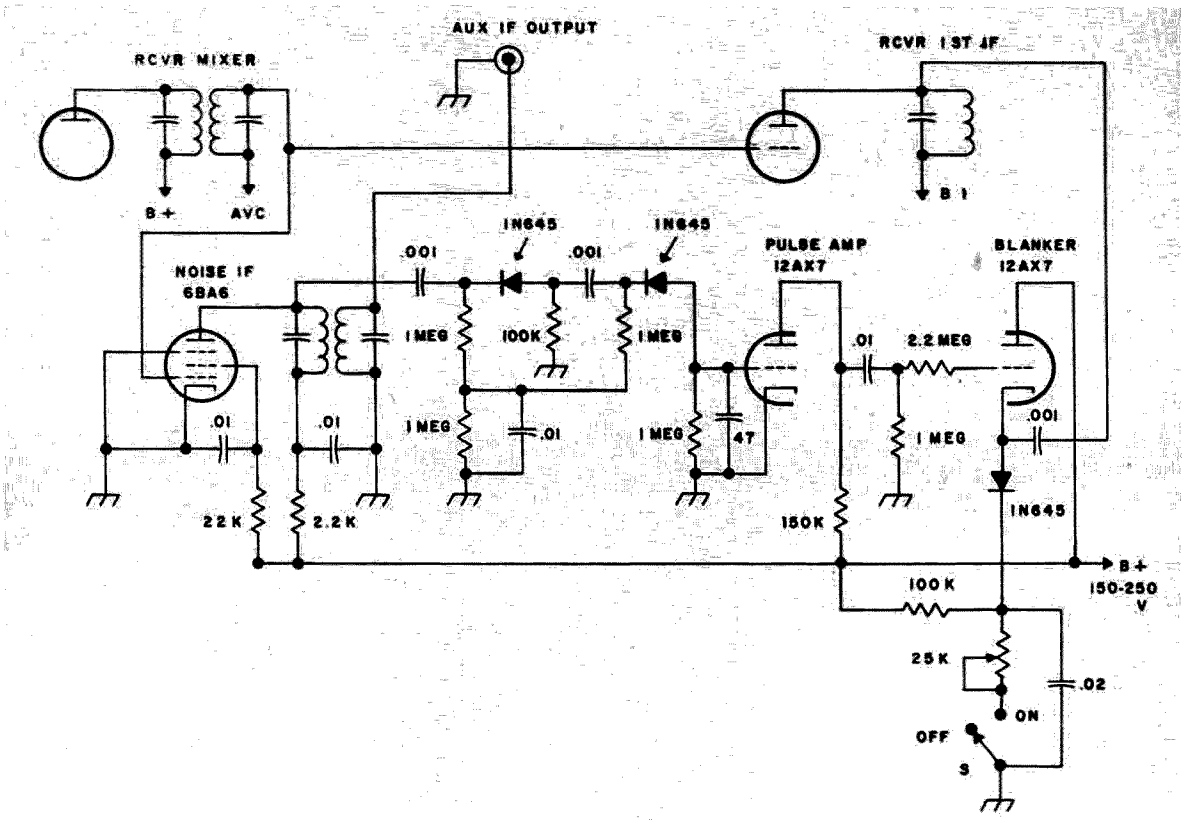
a NOISE BLANKER that works



For pulse-type interference, there's no substitute for a blanker. Here's one that can be built up for less than five dollars...and it can be left in the circuit at all times without degrading normal receiver performance.

For several months now I've been experimenting with every imaginable type of noise reduction circuit. The result of extensive work with audio and i-f limiting and clipping was a growing conviction that the way to achieve truly effective noise reduction was to develop a blanker. Audio limiters and clippers all share one failing: they introduce harmonic distortion which reduces intelligibility and makes for extremely fatiguing listening over the long haul.

I-f limiting and clipping invariably reduce the signal level. Apparently, the more effective this kind of circuit is, the more loss it introduces. If it was to be necessary for me to build an extra i-f stage to compensate for this loss, why not go the route and develop a full blanker? The extra circuitry necessary would not amount to that much more than a clipper and extra i-f stage.

I came up with the following list of basic requirements after analyzing present commercial blankers, as well as a couple of circuits in the ARRL handbook.

1. Blanking must take place ahead of the selective stages to reduce ringing.
2. A minimum of 30 dB of blanking is a prerequisite, based on the performance of current commercial blankers, and

the claims made for other published circuits.

3. Compactness, simplicity, and ease of adjustment are obviously desirable.
4. The blanking action should not materially affect the signal.
5. The blanking action should be inversely proportional to the strength of the received signal.

All in all, five different circuits or combinations of circuits were breadboarded and tested. In most of them it was very difficult to secure a sufficiently low time constant to prevent audible "holes" from being punched in the signals in the presence of noise. In others, serious distortion of strong signals resulted from the inability to secure satisfactory inverse control of the blanking action, proportional to signal strength. Of all the circuits I built up, only one satisfied all the requirements adequately: R. L. Drake's blanker circuit as used in the R-4 series receivers. The purpose of this article is not to set forth an original circuit of mine, but to explain how this exceptionally fine blanker works, can be homebrewed, and integrated into existing equipment.

How It Works

An avc controlled 6BA6 amplifies the incoming *rf* signal from the first mixer and it is detected at D1. The avc control helps accontrol the level at which blanking action

pulse detector D2 proportionally to the strength of the incoming signal. D2 detects noise pulses exceeding the amplitude of the incoming signal, and the resultant negative pulses are used to cut off the first section of the 12AX7 instantaneously for the duration of the noise pulse received. This produces a positive pulse at the plate which in turn is used to turn on the second section.

When the second section is turned on, it draws current, forward-biasing the diode (D3) in series with its cathode for the duration of the noise pulse. When the diode conducts, it grounds the plate of the receiver's first i-f stage, instantaneously cutting off the signal while the noise pulse is present. Noise is literally chopped right out of the signal, while the signal itself remains virtually unchanged in its audible form, though it's really full of infinitesimal "holes." A piece of RG-58 is used to make the connection between the first i-f plate and the 12AX7 cathode through a .001 μF disc ceramic. When the blanker is off, diode D3 is heavily reverse-biased, preventing blanking or random clipping. The 25 kΩ pot is used to complish the desired inverse ratio between signal strength and blanking action. More control is derived from detection at D1; a portion of this voltage is used to reverse-bias

begins. I have used the secondary of the i-f transformer in the blanker to take off the i-f signal for a monitor scope.

Adjustment and Operation

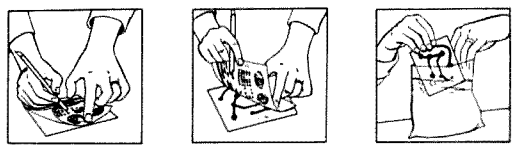
There are no tricks to getting the blanker to work properly, and, if you've wired it correctly, you should find that it works perfectly as soon as three simple adjustments have been made.

1. Make sure that the blanker is off, and tune in a strong carrier — — your crystal calibrator will do nicely. Repeak the first receiver i-f to compensate for the connection to the blanker.
2. Remaining tuned to the carrier, adjust the i-f transformer in the blanker for maximum positive voltage at A.
3. Now find a signal of medium strength which is difficult to copy through heavy noise. (Perhaps you can have someone start your car and rev the engine to create some noise, if necessary). Adjust the 25 kΩ pot for sufficient blanking to enable you to copy the signal easily. You may be able to make the noise disappear entirely. This step requires some judgment, and you may want to repeat it several times under various conditions to be sure you've optimized the blanker's performance.

Once the above steps have been accomplished, you should find that you have better than 30 dB of blanking, probably more — plenty for even the worst conditions — without distorting the signal.

Now, get everything back together again, and be prepared to copy signals that you've never heard before. My QTH is a half block south of some high-voltage power lines. I guess I don't have to tell you what that does to weak groundwave signals on 6 meters . . . it obliterates them! Using the blanker, however, enables me to copy just about everything anyone else does, and a lot of it cannot even be detected (let alone copied) without the blanker.

The nature of this circuit is such that it can be left on at all times, if you wish, without degradation of receiver performance. It's only active in the presence of noise. It's very nearly foolproof, and it shouldn't take you more than an hour to build and install it. On top of that, it's plenty cheap. If you have any kind of junkbox at all, the whole works shouldn't cost more than three or four dollars. You'll find that this blanker will repay this minimal outlay of money and time many times over — and you'll be amazed at what you can dig out of the "mud" with its help.



A few afterthoughts and suggestions are in order. I built the detection circuitry entirely on a piece of Vectorboard which is mounted to the chassis by a small angle bracket. I recommend this approach to save space, as well as for convenience, since this circuitry is quite awkward to mount on the usual tie-lug strips. It is important to retain the exact values of resistance and capacitance shown in the detector and blanking circuitry. Changing them could result in an increased time constant which might cause audible "holes" to be punched in the signal.

The method of applying avc to the blanker *if* may vary from receiver to receiver. This makes no difference, as long as a direct connection is made from the grid of the receiver's first i-f stage to the grid of the blanker's i-f stage. This will couple both signal and avc voltage to the blanker. Diodes D1, D2, and D3 can be nearly any general purpose silicon diode; but D3 must have sufficiently high ratings to handle the voltage drop and current through the 12AX7.

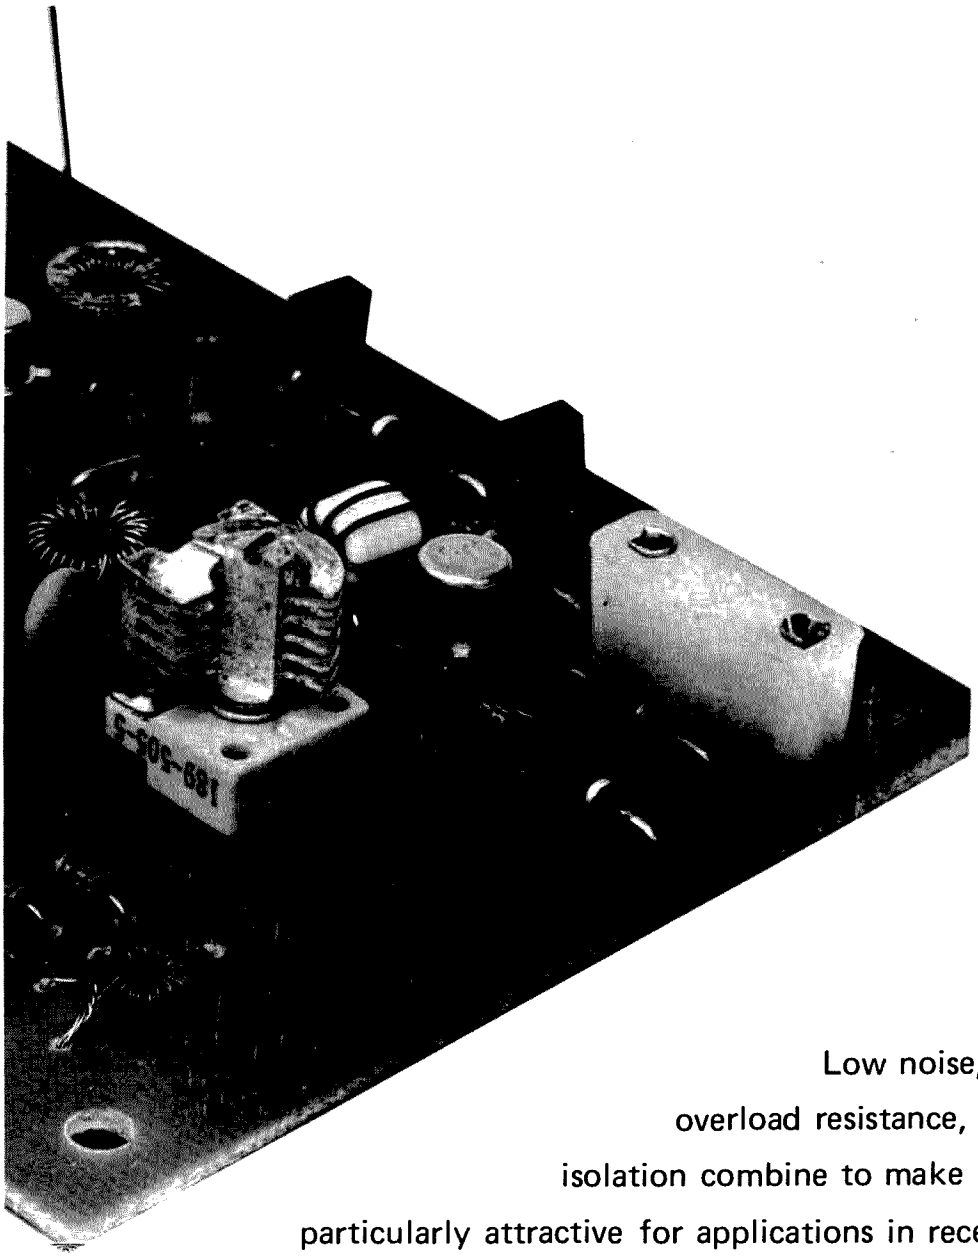
Hot Carrier Diode Mixer/Converter For 2 Meters



The double-balanced diode mixer using hot carrier diodes is enjoying widespread acceptance in commercial and military communications equipment. When properly applied, these mixers offer the designer many advantages compared to the conventional bipolar or field effect transistor approaches. The main advantages are:

- Very good overload resistance
- Low crosstalk and intermodulation products
- Good noise figure
- Excellent local oscillator isolation
- Construction simplicity and ease of duplication
- Can be made into a wideband device

This article describes an easily duplicated 2 meter converter which offers the latest in design concepts.

The detailed workings of the hot carrier diode and its operation in the double-balanced mixer can be found in the references. Briefly, the hot carrier diode is constructed using a PN junction joined to a metal barrier as shown in Fig. 1. This construction technique provides a diode with many advantages over the conventional point contact or silicon PN junction diode. These advantages include low turn-on voltage (410 mV), high UHF rectification efficiency, low diode noise, extremely fast switching times, and excellent diode-

Box 903
Mountain View CA 94040

Low noise, high gain, excellent overload resistance, and a high degree of isolation combine to make the hot carrier diode particularly attractive for applications in receivers and converters.

to-diode uniformity.

The double-balanced diode mixer uses the variable resistance of the diode's on and off state to perform the mixing action, and offers excellent port-to-port isolation by using electrically balanced centertapped transformers. The noise contribution due to the local oscillator is also greatly reduced due to the electrical arrangement of the transformers. Since the diodes and the local oscillator offer no significant noise contribution to the mixing operation, the mixer is essentially a noiseless passive device which has a conversion loss. This conversion loss (typically 5–7 dB for mixers of this type and frequency range) appears as a resistive attenuator when used in a down-converter application. This mixer is a broadband device; therefore, to change the i-f output frequency to suit your requirements, only the local oscillator

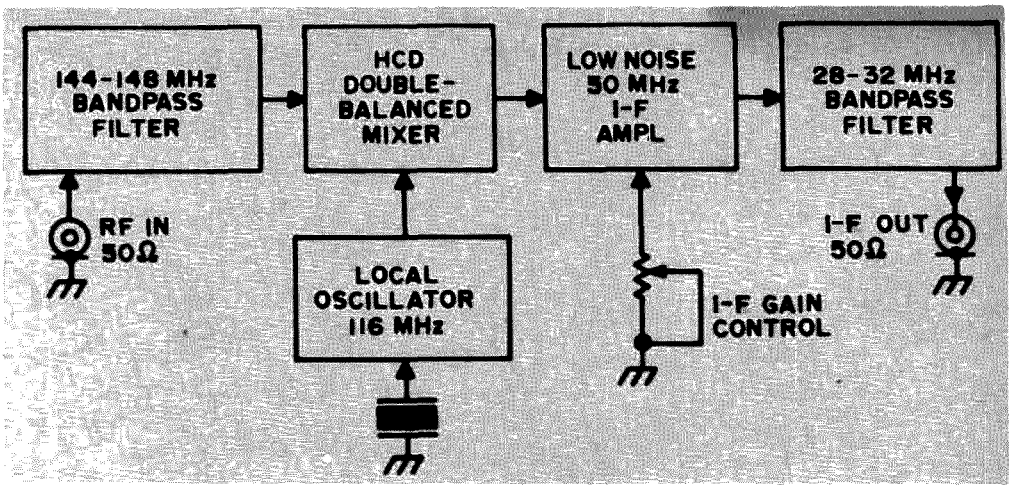

Fig. 2. 2 meter converter block diagram.

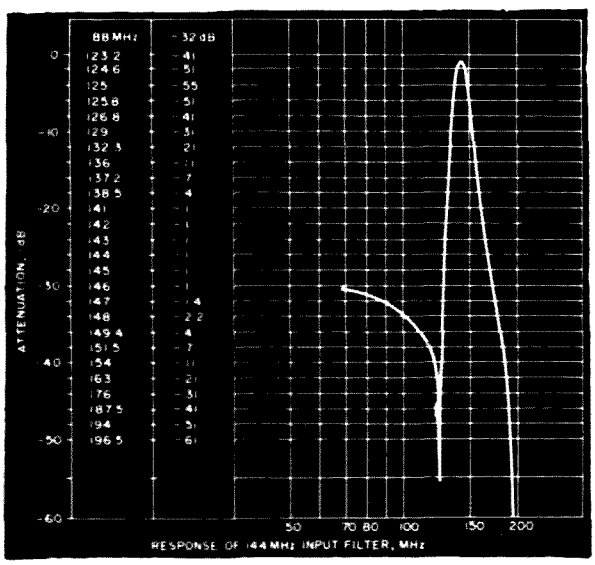
frequency and the i-f amplifier center frequency need be modified.

The block diagram of the converter is shown in Fig. 2. It starts with a bandpass filter centered at 146 MHz. This filter is a critically coupled double-tuned circuit which provides a bandwidth of 6 MHz and an insertion loss of 1 dB. It is necessary to use a bandpass filter ahead of the broadband mixer to eliminate the noise power that would be contributed by the images. The response of the filter is shown in Fig. 3.

Following the input filter is the double-balanced diode mixer. It uses a computer-matched diode quad; the Hewlett Packard HPA-5082-2805 available from your local HP-Neely sales office for $4.40. The quad is composed of selected HPA-5082-2800 diodes which can be used and are available for 99¢, but the matched quad will provide



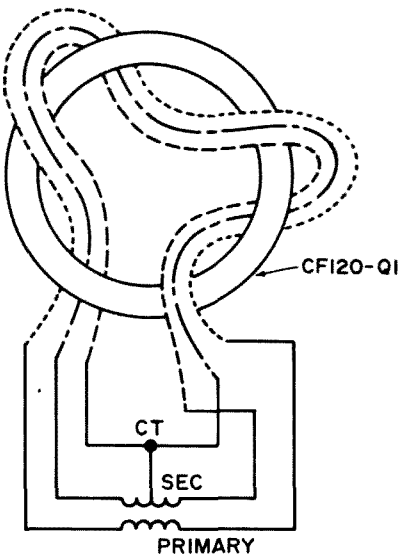


Fig. 3. Response curve showing attenuation vs frequency.

(WIRES SHOWN UNTWISTED FOR CLARITY)

Fig. 4. Toroid winding.

better mixer balance and a lower conversion loss, so it will be worth the extra money. The toroids used are Indiana General CF-120-Q1's available from Newark Electronics for $1.20 each. They are wound with 30, 32, or 34 (AWG) enamel wire. The windings on the toroid are shown in Figs. 4 and 5. Care should be made to insure that the proper winding interconnections are made.

The 30 MHz i-f amplifier following the mixer is a low-noise FET stage. It uses the

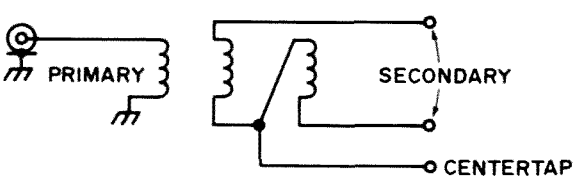

Fig. 5. Schematic of the trifilar toroid connections. (The three windings should be twisted together before winding onto the core.)

RCA 40602 dual-gate FET which exhibits high gain, low noise, and very little reverse capacitance. This low reverse capacitance allows you to build a high-gain amplifier at this frequency without having to neutralize. The second gate provides a convenient way of varying the stage gain so that the converter can be properly matched to your receiver i-f. The gain of this stage is 28 dB with the i-f gain control at maximum and 0 dB at the minimum position. The output of the FET is a double-tuned circuit centered at 30 MHz. It provides a flat response from 28 to 32 MHz with high skirt selectivity. It should be noted that the i-f amplifier following this type of passive mixer must have the lowest noise figure possible as it will directly add to the overall converter noise figure. The use of the FET in the i-f amplifier also allows one to take advantage of the FET's overload capabilities and low crosstalk and intermodulation products.

The mixer's oscillator injection is obtained from a "no multiplication" local oscillator. It uses a seventh overtone crystal at 116 MHz in a common-base Colpitts

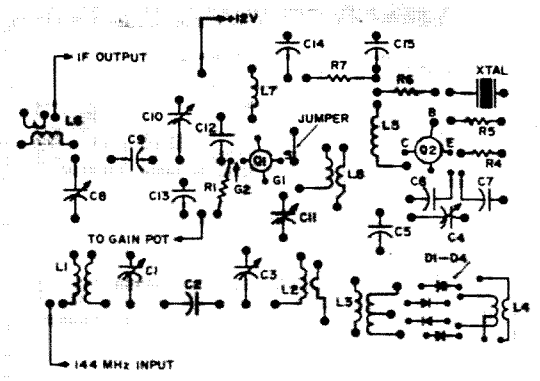

Fig. 6. PC layout (component side of board).

oscillator circuit. The cost of the crystal is about $7.50, but it eliminates the multiplication stages and tuneup required for the tripled 38.666 MHz approach. The "no multiplication" approach also eliminates many undesireable harmonics from being fed into the mixer which would cause unnecessary image and "birdie" problems. This oscillator circuit is easy to get started and it will supply the mixer with about 10 mW of drive. This circuit has been used with crystals from various manufacturers

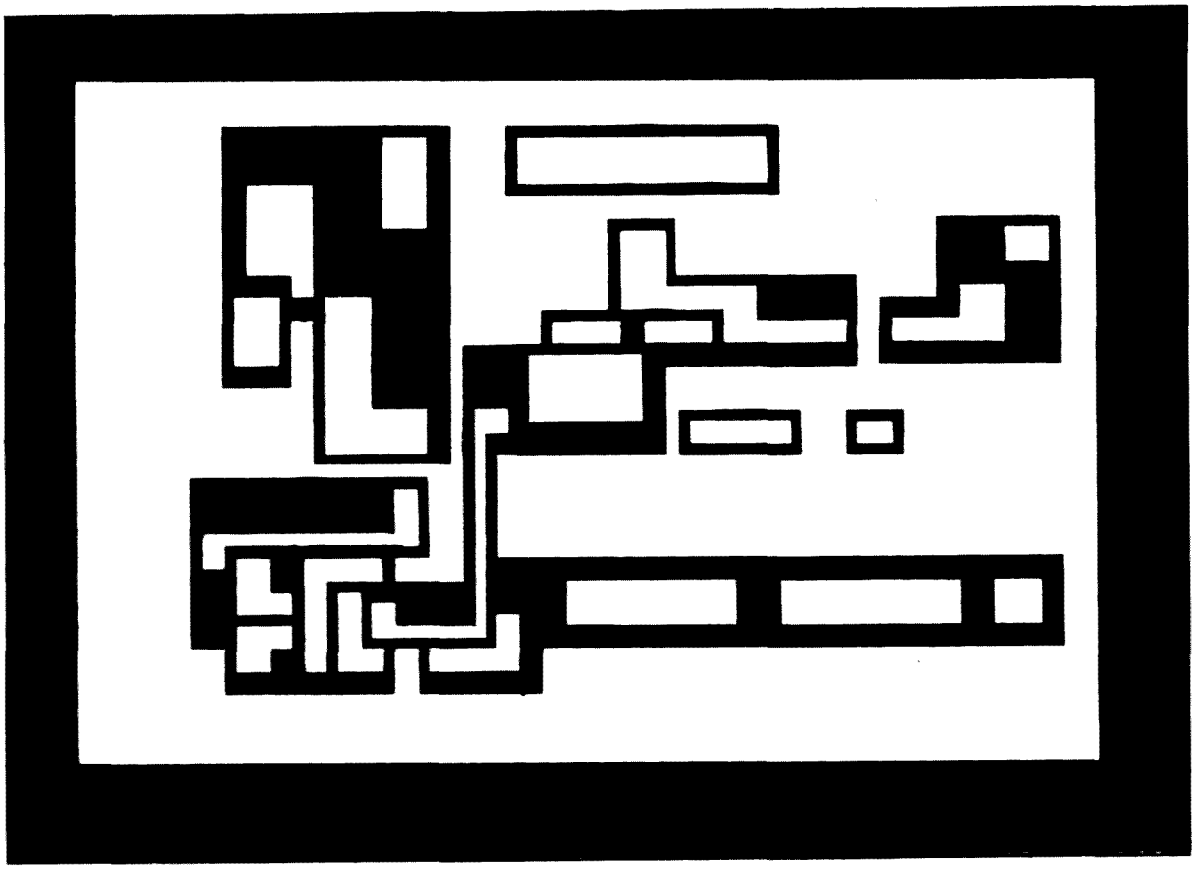

Fig. 7. PC layout (copper side of board)

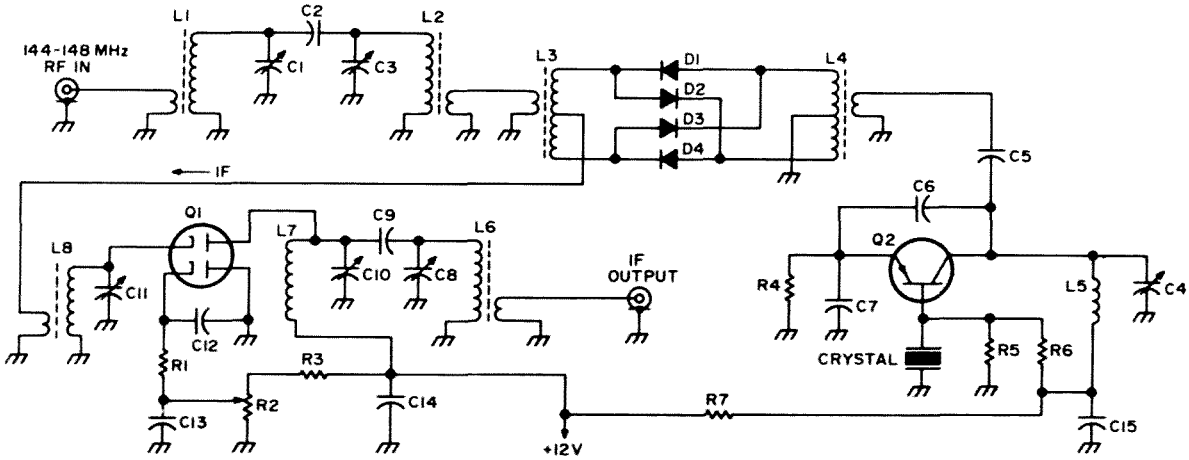

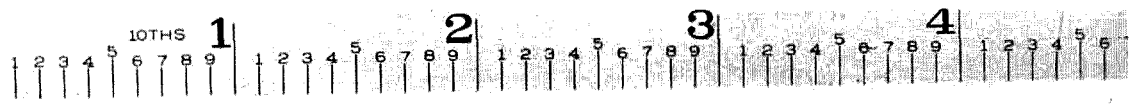

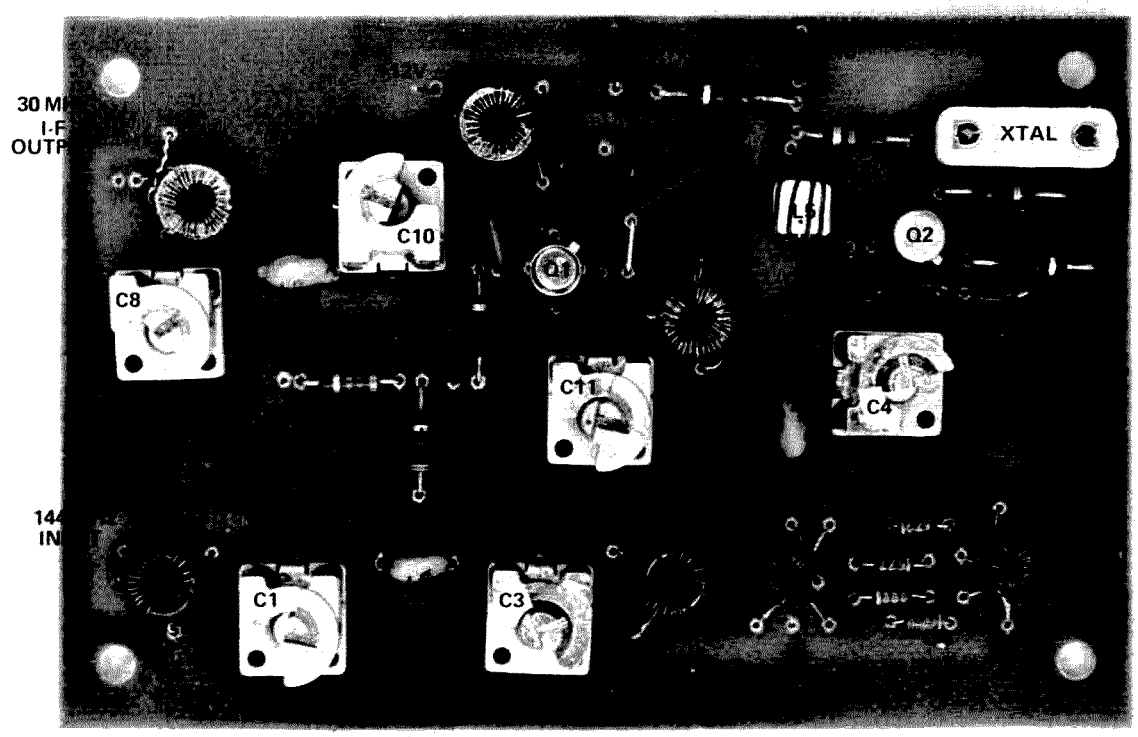

Fig. 8. 2 meter hot carrier diode converter.

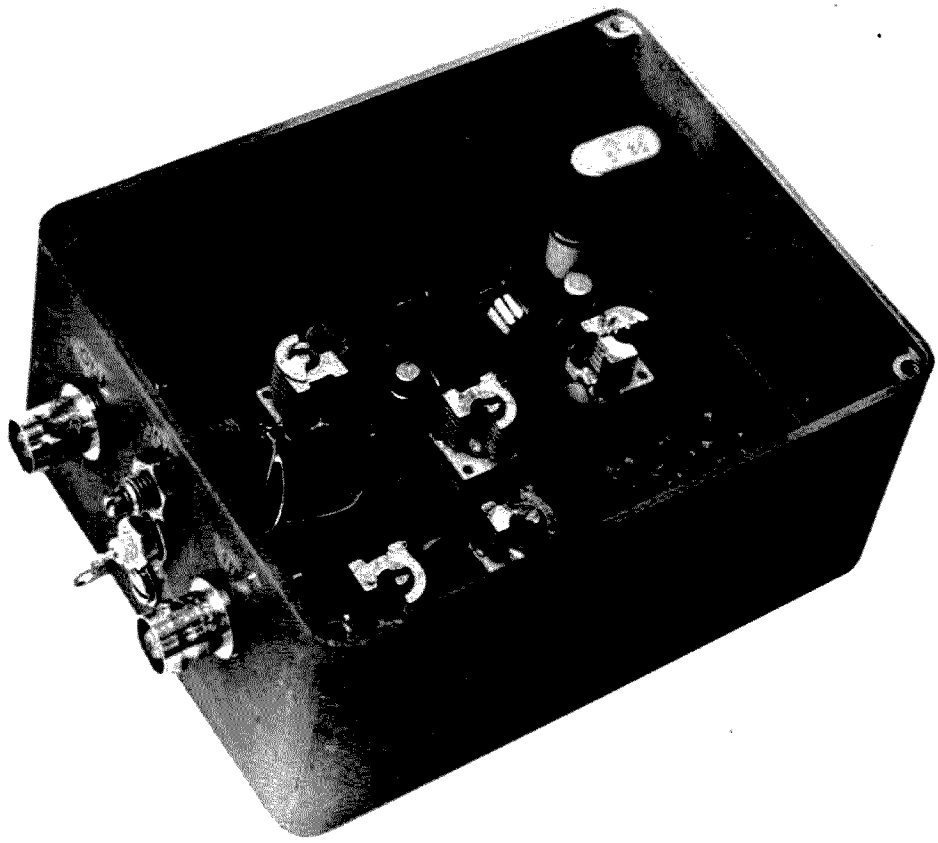

and by others in their converters and it always plays right off. So don't fear getting this 116 MHz oscillator circuit to work.

The printed circuit board layout is shown in Figs. 6 and 7. By using it and the components recommended, duplication of this converter should not be a problem. The use of a passive mixer and an i-f amplifier that doesn't require neutralization makes tuneup very simple.

Alignment of the down converter is a simple matter. First, get the oscillator working and then peak the input filter and the i-f amplifier with a 2 meter signal. The oscillator is started by tuning C4 and using a wavemeter or the diode position on a grid dip meter as a signal indicator. Once you've established that the oscillator is running, feed a 2 meter signal into the converter input and peak the input filter and the i-f

amplifier for a maximum S-meter reading on your receiver. Optimum flat bandpass characteristics can be obtained for the input filter and the i-f amplifier if a sweep generator is available. Once the circuits are tuned, the i-f gain control is adjusted until the converter noise just overrides the receiver's noise.

Noise Figure

Since we are dealing with passive devices, which have insertion loss instead of gain, this loss is treated like an attenuator. The input filter, with insertion loss of approximately 1 dB, is followed by another device, the mixer, which has an insertion loss of about 6 dB (for a total of 7 dB). The noise figure of the i-f amplifier is 2 dB and, since a total of 7 dB attenuation appears ahead of it, the overall noise figure of the converter is 2 dB noise plus 7 dB attenuation – or 9 dB total.

The completed converter has a noise figure of approximately 10 dB, which will be more than adequate for local ragchewing, mobiling, and FM repeater work. Naturally, for weak-signal work it will be necessary to put a low-noise rf preamplifier ahead of the converter. The image rejection is determined by the input filter and for the worst-case image band of 84–88 MHz, it will provide 30 dB rejection. All other images are down better than 50 dB.

D1, D2, D3, D4: Hewlett Packard HPA-5082-2805 diodes.
Q1: RCA 40602
Q2: RCA 2N5187

The converter will form an excellent base around which a top performing and versatile weak signal system can be built. You'll be pleasantly surprised by the clean quality of the converter. There will be a scarcity of birdies and images and it will be harder for strong nearby signals to overload the converter. . . . WA6NCT ■

EXAMINING FM REPEATER OPERATION

Robert Kelty WB6DJT
2661 Carol Drive
San Jose CA 95125

Interest in amateur FM repeaters has grown in less than ten years to be a significant segment of VHF activity to which even diehard traditionalists are now turning. Hardly a major community exists around the country in which there is not some FM operation; and now, equipment suppliers are beginning to give serious attention to FM'ers. Repeaters grew up under regulations not originally envisioning such operation, yet were recognized in general as remotely controlled stations. Traveling around the country, one readily sees that each operates in a slightly different manner, with groups tailoring their nets to their own requirements.

Until late 1968 the ARRL, amateurdom's "official voice," hardly knew what a repeater (or remote base) was, and League publications carried little more than occasional mention. Meanwhile growth and interest has continued. Operation of remotely controlled equipment for group benefit has a certain cost reality; a successful repeater calls for organized support, often in club form, to insure permanency. In California a relay council was organized as early as 1966 to administer matters such as frequency coordination, standards, and to do advance planning at a level that would benefit all repeaters. Throughout the country individual groups began interfacing or providing means to tie to each other and the ARRL Board of Directors saw that repeater people were serious about what they were doing and had the finances and organization to continue growth almost without limit. The publication of an FM Repeater Handbook[1] in

[1] Radio Amateurs FM Repeater Handbook, Ken W. Sessions, Jr., Editors and Engineers, New Augusta, Indiana.

1969 gives adequate evidence that remote operation by VHF and UHF amateur operators from rf-advantageous permanent locations is indeed here to stay.

The importance of a large new segment of amateur interest was wisely recognized by ARRL directors almost belatedly and, seeing that the "Buffalo Petition" was a seriously considered necessity, they moved in 1969 to appoint a special committee to study repeater activity with an eye toward recommending FCC rules changes that would both correct inadequately written sections and enhance operation. In addition, the board voted for ARRL involvement at headquarters and for inclusion of a chapter on repeaters in the yearly handbook to stimulate interest. A separate League VHF handbook is still under consideration.

In 1970 the committee's final report and recommendations will be released and hopefully rules changes will be implemented to permit operation closer to realities which have often been discussed by "repeater people." It is to these proposed changes that we now turn our attention.

Getting the License

Licensing of a remotely controlled station has never been a major hangup, the procedure being almost adequately described in section 97.43 of Regulations. The applicant conforms in part by checking certain blocks on his standard form 610B and by submission of block diagram and description of proposed means of controlling the installation to prevent operation not in compliance with regulations.

For the most part, systems run cleanly and the intent of regulations is not circumvented purposely to the detriment of the service. Still, repeater operation is more closely comparable to PSIT[2] radio services rather than to "ham" type activity. Fixed, portable, and mobile operation on fixed frequencies naturally became abbreviated to the point that callups, logging, identifying, and control methods are somewhat different from that in which an operator hunts for a QSO with someone he may not know. Net operation always seems to be a cohesive that fosters good operating procedures because of the necessity of a good "net image" in the eyes of outsiders. The occasional maverick soon finds himself unwanted.

One of the rule sections being carefully considered by the repeater advisory committee has been licensing. It has been agreed in repeater circles that the present "remotely controlled station" category has too many implied restrictions.

In essence, a remotely controlled station is not described as a mobile relay (repeater), one which is used to extend mobile-to-mobile communications range. It appears that this valuable and now very popular application of equipment was not considered in original rulemaking and that the authors only thought in terms of remote base operation by individuals. The Commission has nevertheless considered applications on individual merit, granting licenses where the intent and presentation was in order. Hundreds of such installations are now in operation on prime coverage sites serving many thousands of VHF and UHF enthusiasts.

It is difficult to imagine that there are any licensees who don't recognize that the letter of the rules under which they operate is not being complied with. Many have tried to minimize this enigma by licensing as many as 38 individual control points,[3] licensing wives who are at home most of the day, placing control stations at places of business where monitoring can be accomplished, relying on an unlisted telephone which will deactivate the transmitter when dialed, or via a primary power control switch arrangement at a 24-hour answering service which can be turned off by an unlicensed operator on request. All are honest attempts to comply as closely as practical. All are clever interpretive applications.

[2]Public Safety, Industrial, Land Transportation, often called "commercial" land mobile.

[3]Grizzly Peak VHF Amateur Radio Club, Richmond, California (WB6AAE).

Properly licensing and operating a station is even more involved when one considers not only the VHF mobile relay but interfaced UHF, interconnection to other stations, extension to multiple pickup receivers, or selectively keying transmitters. Configurations take many forms.

A workable solution and one which the California Amateur Relay Council endorses is to establish two additional categories of station under Section 97.3, Amateur Unattended Station and Amateur Repeater Station, then license on a per case basis as described under 97.43 (with certain modifications), submitting proposed configuration as at present. Licensing procedures would thus be preserved more realistically.

Control Methods

Maintaining control of unattended transmitters has been a handicap to licensees because of rules rather than equipment. Monitoring of the emissions of remote transmitters from the licensed control point(s) plus provision of a 220 MHz (or above) control path (or wireline) places restraints on a system unnecessarily. Unattended-station users have reached a point of proficiency and sophistication to allow control on the VHF input channel above 50 MHz with adequate protection against stuck transmitters, deviations from terms of license, or undesired radiations. Timeout devices, carrier coding, or other similar devices are this protection. Although station responsibility must remain with a "trustee of license," he can easily record individual stations who normally use the remote station in his log once or the occasional transient at each occurrence.

Currently popular methods of insuring that only authorized stations perform the control function (placing the remote transmitter on the air) include "dial up" for the period of use, number sequencing known only by authorized stations, and "per transmission" coding (pulse tone or continuous subaudible). Occasionally rumblings are heard concerning discrimination against outsiders or maintaining "closed" relays but trustees are merely maintaining control while insuring that cost sharing is in effect. Purists new to VHF repeaters seldom see that the co-op station is a relatively new concept borrowed from "business radio" until they realize dollar investment in equipment, maintenance, and club costs.

As for suspending radiation in the event of deviation from terms of license, a means can be provided and described in license applications. Certainly a trustee is clever enough to meet this requirement in his own way when held responsible. Amateurs are marvelously self-policing by nature and it has been proved repeatedly that the willful violator has no regard for rules, ethics, or propriety no matter what constraints are placed on him. Responsibility can be enforced should such need arise by virtue of the trustee's application, license grant, and terms of license.

Identification

Despite relaxation of identification requirements in the past two years, many amateurs, especially those who have operated below 30 MHz for long, tend to dual identify, give location, and identify again. At one time this may have been practical and of some value, but today – especially when operating through remote VHF equipment, which usually is devoid of marginal signals – there is little need to prolong the callsign ritual. Operators who feel insecure or wish to prove to listeners their superb range will continue to take opportunities to give mobile locations frequently but the practice seems merely for display. Ragchewing will still be popular but has taken a slightly different hue and those operators who are still yearning for a wall certificate for staying on the air for extended periods have found that laudatory rewards are hard to come by on FM.

Repeater people have discussed extensively the time interval that should be required between callsigns and it is generally felt that 10 minutes is not asking too much. Still, the operator who becomes engrossed in multiple-party exchanges sometimes lets one of these intervals slip

by. The fluid pattern of who is talking to whom is often difficult to confine in time frames.

Identification of remotely controlled transmitters at intervals, in voice or electromechanically is another area describable in shades of gray. A remote base can be identified without confusion, as can a repeater; however, when several people operate the station, who gives the assigned call? Or on a remote base with a UHF "up" and "down" link, is identification of the down link to be made? Or for that matter is it to be continuously monitored? Another level of interpretation is added when more than one station is operated simultaneously or interfaced. Most of us just tend to throw in a series of callsigns and let it go at that, for better or worse.

In "preliminary study committee" discussions, three-minute ID of repeaters has even been proposed for rules although saner types still feel little need to identify equipment to death unless they feel insecure among their listeners. The FM Magazine petition, a year in the making, is now before the FCC as RM-1542. This petition suggests a three-minute ID, too, but on a slightly different – and more reasonable – basis: it would have the ID take place after each three minutes of actual on-the-air time, rather than each three minutes of overall operation. But I think the most practical procedure would be to authorize "no announcement of callsign when station is operated as a repeater or unattended station," similarly to other land mobile licensees who request this attachment to their terms of license. We identify our own stations during exchanges, and the remote equipment carries this intelligence along with adequate indication to the ear that one is listening to a remotely controlled transmitter. Making identification permissive rather than mandatory, as Jay O'Brien (ARRL repeater advisory committee member) suggests, still leaves a group with the ability to advertise who they are. Or if they really like to fool around with identification, there probably isn't anything wrong with interesting "canned" announcements done by well known amateur voices as some Southern California addicts like to do. This type of creeping "Hollywoodism" is native to Southern California where it somehow seems fitting.

Station Logging

Log requirements for unattended stations are not defined in FCC Rules, Part 97.103 except that one could contend that a control station should comply with each subsection and record time of each sequence of communications, signature of operators using the station, and location of stations transmitting. To anyone who has listened to a repeater, even briefly, this is a tall order. Actual logs that might be examined reflect a very liberalized application of our outmoded rules for this type of operation, where several mobiles might be involved at any one time, traveling various routes. Hand-carried portables are becoming quite popular and present another variation. Minimizing of logging requirements is certainly in order.

It is close to universally agreed that recording time of retransmission capability, technical parameters such as power, frequency, and emission, date and time of changes of items to be logged, and signature of operator making adjustments comprise an adequate log. Redundancy of items that appear in individual logs should be eliminated. RM-1542 would have a "maintenance" log only, filled in during periods when the repeater site is visited for service or repair.

The ARRL study group has done a comprehensive job of evaluating the amateur repeater picture, drawing from its members as well as from discussions with repeater groups around the country. While this review reflects quite closely the interim reports of that committee, final report has not been completed and probably won't be until early spring.

We who have been involved with repeaters for the past decade look forward to rule changes by late summer of 1970 with the realization that by so doing the FCC will be formally recognizing the importance of this dynamically growing segment of amateur activity.

a REPEATER CONTROLLER

The myriads of mechanical contrivances that repeaters inevitably wind up with can be replaced with transistor equivalents...with a resulting increase in system reliability and decreases in headaches for the repairman.

After operating an amateur repeater for several years it became quite apparent that the majority of our repeater failures were caused not by a malfunction of either the receiver or the transmitter, but by a failure of the carrier-operated relay (COR), the three-minute mechanical timer, or the *hang-in timer.*

We have been using the standard Motorola tube-type COR with a Telechron drive three-minute timer and an Agastat dash-pot timer for hang-in. We often had trouble with the Agastat mechanically shaking things loose in the repeater and middle-of-the-night wife-type complaints about the noise, particularly when a mobile was putting in a "picket fence" signal at 2 a.m. It's like waking up to a machine-gun.

In an attempt to eliminate the problem associated with these mechanical devices we began to work toward a solid-state system. Our objective was to reliably key the transmitter on both weak and strong signals, without any buckshot, and to provide carrier hang-in, automatic tone CW identification and a three-minute timer. We accomplished this with a Schmitt trig-

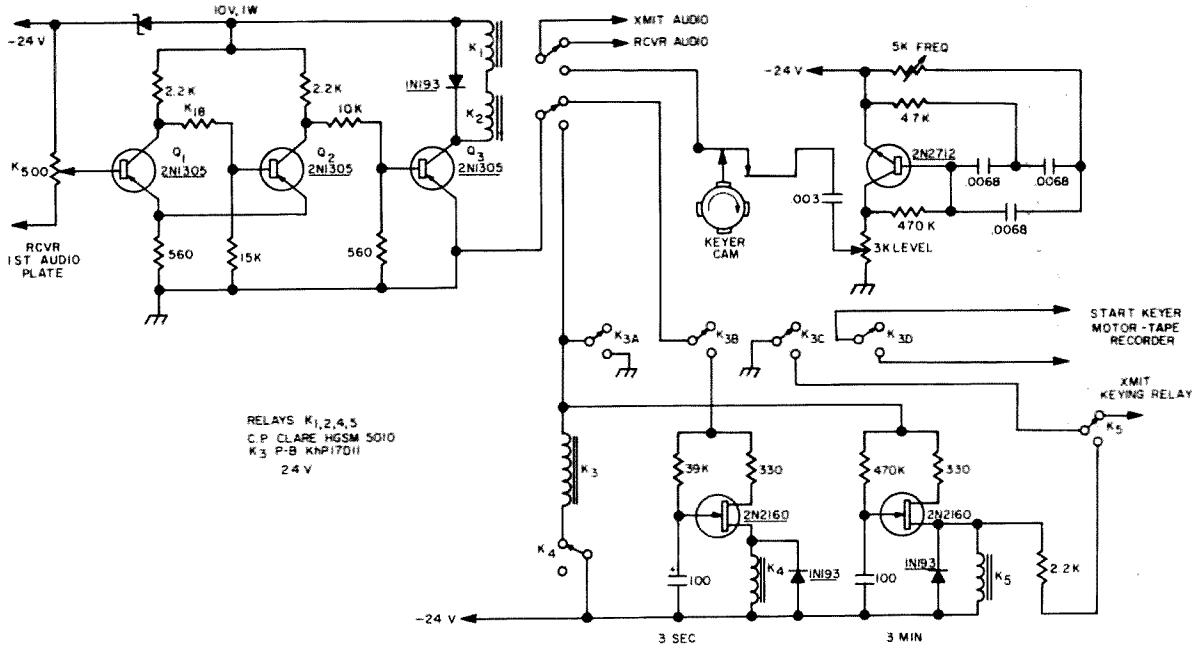

Fig. 1. Schematic diagram of repeater controller circuit.

ger operating from the change in plate voltage of the first audio amplifier in our GE Progress Line receiver.

The Schmitt trigger requires only a 2V change in a negative direction to switch on properly, due to the regenerative feedback of the direct emitter coupling. (Refer to Fig. 1.) Once it has switched, Q3 sees the 8V change on the collector of Q2 and turns on, causing series-connected relays K1 and K2 to close. This circuit and the relays have the capability of switching at speeds up to 20 kHz. Once K2 has closed, K3 latches itself closed through contacts K3A. When this occurs, the transmitter is keyed via K5 and K3C.

Since relay K3 is latched closed, when the received carrier drops out it cannot open and let the transmitter turn off; however, when relay K2 opens, voltage is applied to the three-second timer via K3B and K2, which causes the 100 μF capacitor to charge through the 39K resistor. When the capacitor charges to the breakover voltage of the 2N2160 unijunction transistor, it then discharges into the coil of relay K4 causing its normally closed contacts to open momentarily and allow relay K3 to reset.

In the interim period after K2 opens, K1 has switched the transmitter audio input from the receiver to the CW keyed tone for identification purposes. This provides an automatic "ident" every time a mobile releases his microphone. It also eliminates the squelch-tail noise burst from the reeciver since the Schmitt trigger will reset faster than the receiver squelch.

In the event an input signal is present in the receiver for longer than three minuts, another unijunction transistor timer — which starts its timing cycle as soon as the transmitter is keyed — will time out and latch relay K5 closed. This shuts down the transmitter until such time as the input signal is removed and the three-second timer times out and resets relay K3. When relay K3 opens, both timers are instantly reset (no waiting for the gears to unwind in a mechanical timer).

The tone oscillator frequency is set to 1800 Hz to allow its use for actuating other devices in the control link system on 450 MHz. A potentiometer can be bridged from the tone oscillator output to the transmitter audio input to provide a 1 Hz deviation of the transmitter on top of the receiver audio. This tone can then be

used to key a 450 MHz link to another site.

In our system we utilize a 2 meter receiver feeding a 450 MHz transmitter (which keys a second 450-MHz-to-2-meter transmitter at a remote site). The tone gives us tone control of the remote transmitter as well as auomatic identification of both transmitters. We can also control the remote site by use of 450 MHz from our control points; in fact, we occasionally operate crossband to 450 MHz mobiles.

Our repeaters were built by using old, wide-drawer, GE MTS units and replacing the vibrator transformers with ac transformers. The controller mounts where the Secode was installed originally. It makes a nice compact repeater that can be carried in one hand.

Construction

The PC board can be laid out by first cutting the board to size and then drilling the required holes at the proper locations. Then, using the *rub-on* PC board decals, the proper circuit layout can be made easily right on the copper. If you have relays which are electrically similar to the photo of Fig. 2, simply drill holes and position the layout to fit your parts.

After laying the board out, wipe the board with a cotton sponge soaked in mineral spirits to remove the excess adhesive (which tends to ooze out from around the rub-on decals. This will give much sharper lines after etching in ferric chloride. To remove the decals after completion of the etching, we used a piece of steel wool (which also cleans the copper and makes soldering easy).

The board layout (shown full-size in Fig. 3) was made to fit an Amphenol 143-015-04 edge connector; however, the wires to the repeater can be soldered directly to the circuit board if desired. It does facilitate servicing and testing the unit if a connector is used. Figure 4 is a reduced drawing of the component side of the board.

The circuit diagram shows a 5K potentiometer in the tone oscillator to adjust the frequency; this is really not necessary unless you are going to use a tone decoder in the system that requires a specific frequency. In our system, we used a fixed resistor selected to produce 1800 Hz. Also, you will note that there are no connec-

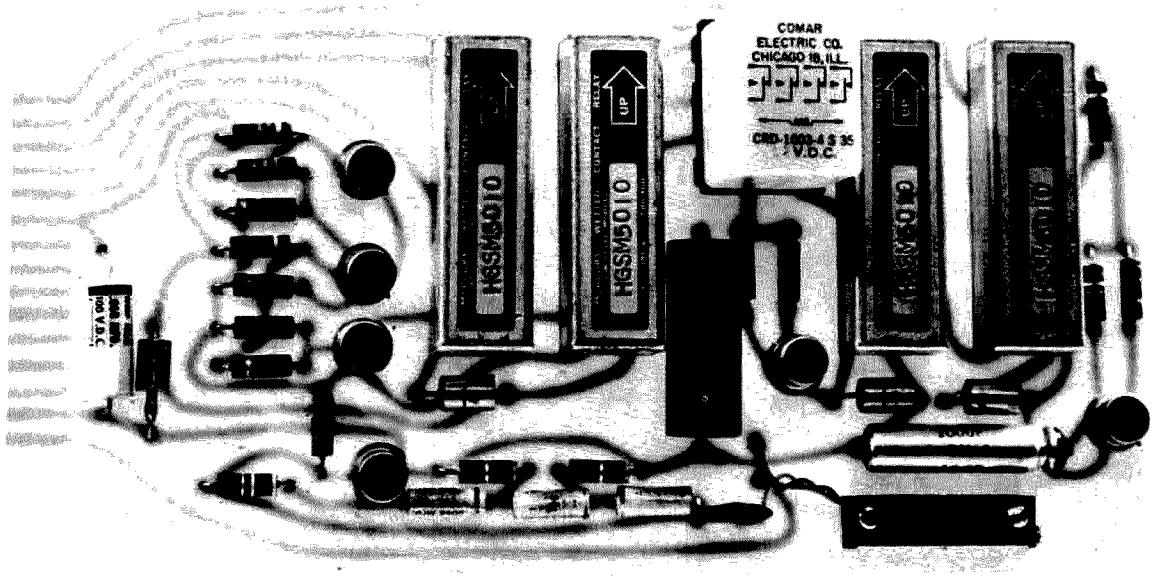

Fig. 2. A single circuit board holds all relays and other components of repeater controller.

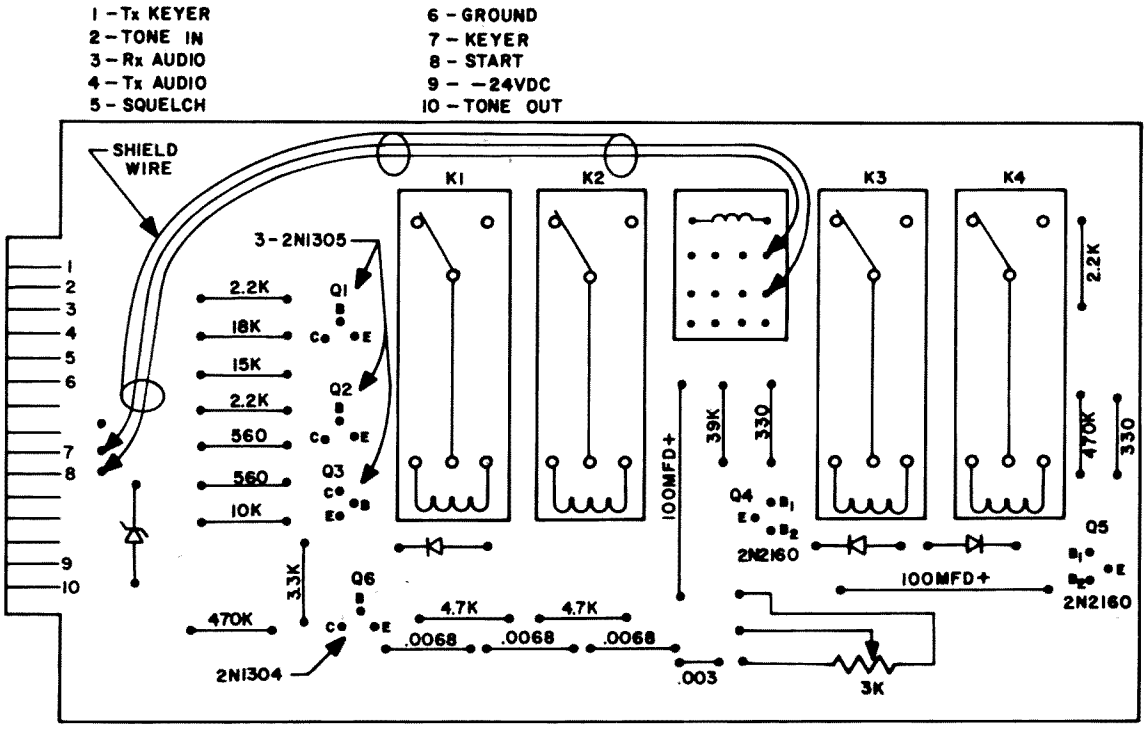

Fig. 4. Proportionately reduced sketch of board shows coding for components and wiring interconnects.

tions from section D of relay K3 to the edge of the PC board. Since this set of contacts switches commercial 115V power, we found it necessary to use a two-conductor shielded wire directly from the relay to the edge connector to eliminate hum pickup in the transmitter audio.

The controller can also be used in continuous-tone-squelch (CTS, Private Line), repeater systems where it is desired to key the repeater with the continuous tone transmitted by the mobiles, by using the circuit shown in Fig. 5. In this operation, When the reed contacts close, the 0.05 μF capacitor charges to the 24V supply, which is then applied to the base of input transistor Q1. This transistor then operates the controller and keys the transmitter. The time constant of the *RC* network is long enough to prevent the controller from following the momentary-contact closure of the reed. Since some reeds have a tendency to remain vibrating longer than others after removal of the input signal, you may wish to vary the value of the 0.05 μF capacitor as well as the input

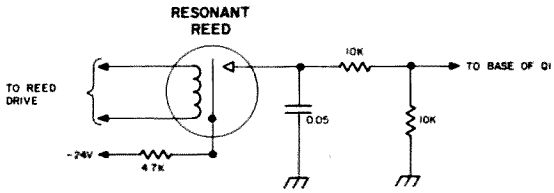

Fig. 5. PL-reed interconnections for use with continuous-tone carrier-squelch systems.

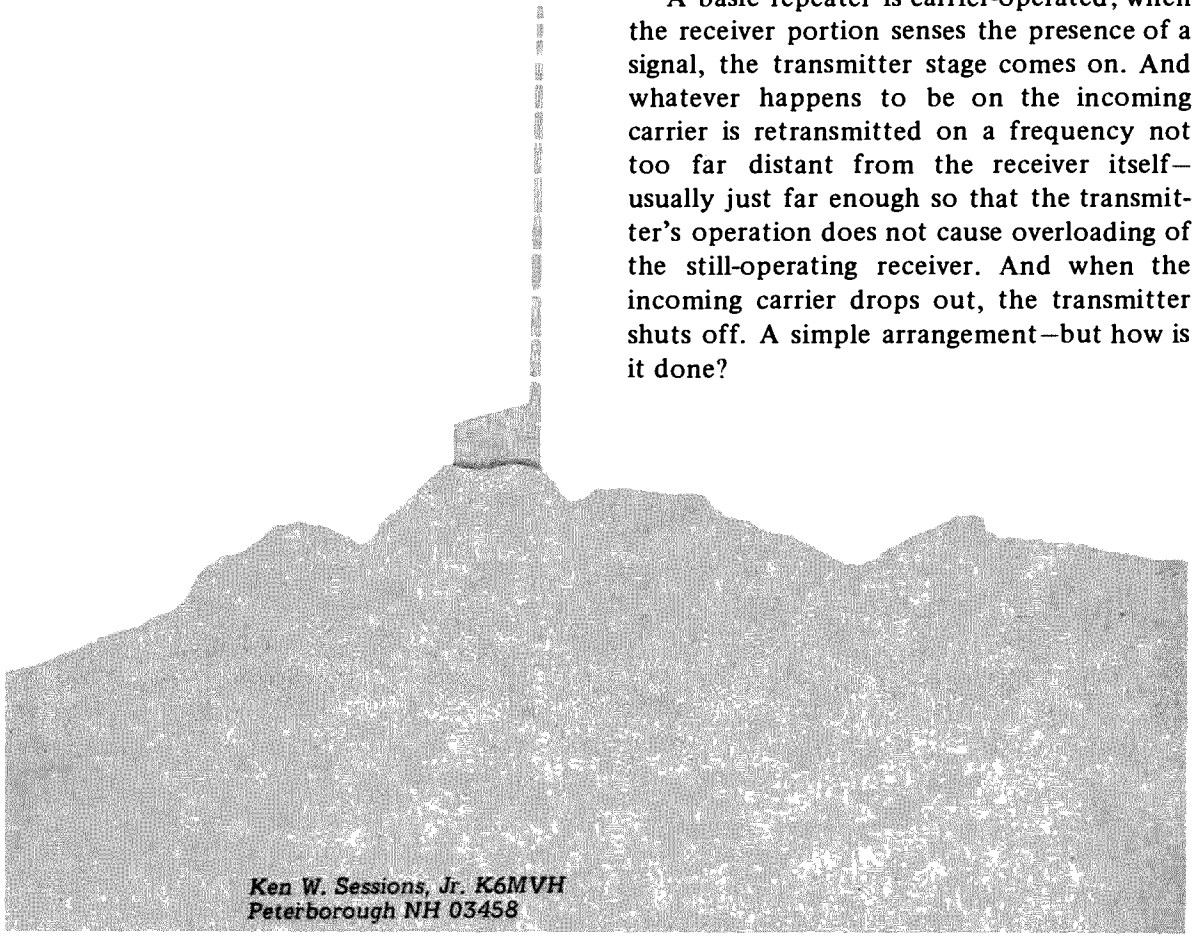
drive to the reed coil so that the repeater audio will be switched to the tone oscillator input in as short a time as possible after the tone input is removed from the reed. This will prevent receiver squelch noise from being transmitted momentarily at the end of each mobile transmission. This problem is minimized if your mobiles are equipped with a squelch-tail eliminator circuit, which provides a short burst of tone 180 degrees out of phase with the normal transmitted tone at the end of each mobile transmission, thus providing a damping action on the reed relay to stop its vibrations.



. . . WA4YND ■

UNDERSTANDING THE CARRIER-OPERATED REPEATER

The complicated repeater is not really so complex after all...it's only a matter of understanding the simple operations that are taking place when somebody transmits on the input frequency.

In spite of what the local repeater talent would have you believe, the big machine up there on the hill—or on the top floor of the city's biggest building—is really a pretty simple arrangement of gear. That is not to say that it hasn't been sophisticated, with the incorporation of perhaps a remotely controlled telephone, some sexy control devices, or maybe an automatic input-frequency switching and selection system. But strip off all the chrome and there's not much dazzle left. A repeater is something anyone can build—and without as much effort as you might think.

A basic repeater is carrier-operated; when the receiver portion senses the presence of a signal, the transmitter stage comes on. And whatever happens to be on the incoming carrier is retransmitted on a frequency not too far distant from the receiver itself—usually just far enough so that the transmitter's operation does not cause overloading of the still-operating receiver. And when the incoming carrier drops out, the transmitter shuts off. A simple arrangement—but how is it done?

Ken W. Sessions, Jr. K6MVH
Peterborough NH 03458

Understandably, a repeater is a bigger mystery to the devoted AM operator. His thinking is limited generally to the workings of the typical AM receiver, and he finds it difficult to see how a receiver can be easily and cheaply made to operate next to a transmitter on the same band without "blocking." He may also have trouble understanding how the transmitter of a repeater can be made to come on without fail when a signal appears, yet NOT come on when noise and garbage are present on the repeater input channel. Which brings us to the reasons why VHF repeaters are virtually always FM.

It is not within the scope of this article to get involved with AM versus FM in terms of operational performance. There are many convincing arguments for FM on that basis alone, but they are, after all, just that: arguments. The prime reasons that repeaters are made to operate in the FM mode are that FM receivers are inherently less susceptible to the normal interferences of the amateur bands and FM receivers are factory-equipped with electronic switches capable of reacting to the presence or absence of legitimate signals.

As it happens, the typical interference noises that occur on the VHF bands are amplitude-modulated. Fortunately, FM receivers are, by their nature of operation, deaf to AM signal components. FM receivers have built-in limiters that reject amplitude-modulated signals. When the AM signal is riding on a healthy carrier, the FM receiver filters out the audio completely and permits only the rf to come through. If the AM signal is weak and noisy to start with, the FM's electronic switch doesn't even believe it's a signal at all, so nothing gets through to the speaker—not even the noise.

The electronic switch is a squelch. To the wives of hams, it is perhaps the greatest invention since earplugs. The squelch on an FM receiver keeps the audio amplifier (and, thus, the speaker) shut off unless a definite signal is present. The big difference between the squelch on an FM receiver and one on an AM receiver is that the FM squelch can't be fooled by noise.

The fact that FM squelches are trick-proof makes them particularly adaptable to repeater applications. If the squelch is used to trigger the transmitter when a signal is sensed, and to turn the transmitter off when the signal goes away, the mysteries of carrier operation begin to disappear. An AM repeater operated by the squelch typically found in AM receivers would keep the repeater transmitter keyed every time the noise level at the repeater site rose a bit. And if the repeater were adjusted to compensate for the noise, half the signals on the input frequency wouldn't be capable of actuating the repeater.

This can be explained on the basis of another phenomenon: For more reasons than those already cited, weak FM signals are virtually noise-free while weak AM signals must compete with the noise. (This statement is made with the assumption that the listener is receiving on a receiver designed for the mode. Many would-be FM'ers never quite made it over from AM to FM after comparing AM signals with those of FM and deciding that, watt for watt, AM was better. But they made their judgments based on comparisons made with their AM receivers! All the noise that was there—but unhearable by the FM receivers—probably all but wiped out those "band-wasting" FM stations.)

Where repeaters are concerned, noise works to the advantage of the FM'er, even though to the detriment of the AM'er. The reason: FM squelches are noise-operated; the higher the noise level on the band, the less apt the repeater will be to get keyed on. A signal, regardless of its strength, has the peculiar characteristic of quieting the noise. And with carrier operation, when the noise goes, the repeater transmitter comes on. Since noise is always present in the absence of a signal, the transmitter of a carrier-operated repeater cannot be keyed unless a signal is present.

A typical FM squelch circuit is actually a very simple device. Its formidable appearance on a receiver schematic is attributable to the Rube Goldberg manner in which it operates. Consider the block diagram of Fig. 1, where the last four stages following the low i-f of a General Electric Progress Line FM receiver are pictured across the top. The audio-carrying low i-f signal is fed from the

VHF FM MONITOR RECEIVER

100% MADE IN U.S.A.

Only $79.95 Postpaid in the U.S.A.

The new **VANGUARD FMR-150** is not just another frequency converter but a complete FM receiver with outstanding performance.

Check the following features and see why it's the best. Collins IF filter for separating those closely spaced stations you hear together on other sets● Double conversion to eliminate interference from image frequencies● Dual Gate MOSFET RF stage for low noise. .2 uv. sensitivity, and minimum cross modulation● Automatic squelch for eliminating noise● Self-contained speaker● Operates on 12v. D.C. negative ground● Heavy gauge anodized aluminum case 6" x 7" x 1-3/8"● Provision for 4 crystal controlled channels at the push of a button● One channel of your choice supplied with receiver. Additional channels available just by plugging in another crystal at $4.95 ea. No need to buy another RF unit as in some other sets● Factory tuned to cover any 6MHz segment from 135 to 175 MHz.

HOW TO ORDER: The **VANGUARD FMR-150** is available only direct from our factory. Include remittance in full plus sales tax if you reside in N. Y. Be sure to state the 6MHz segment you will want to cover and the exact push button frequencies to be included.

VANGUARD LABS Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

second limiter to the discriminator, which separates the af from the rf, and feeds the audio to the amplifiers and speaker. By

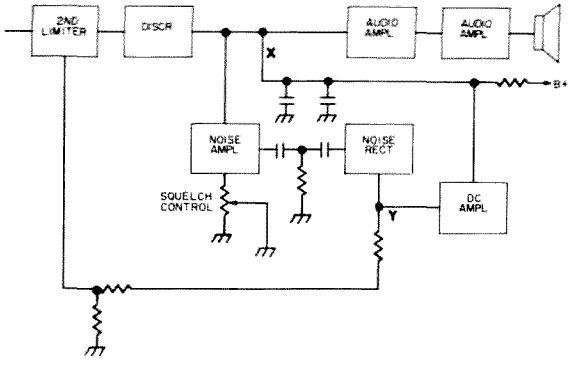


Fig. 1. Combination schematic and block diagram showing squelch arrangement in typical FM receiver.

electronically turning the audio amplifier on and off, the signal reaching the speaker can be controlled. And this is precisely the function of those elements shown below the four top blocks.

The object of the network of components in the squelch train is to provide a negative voltage at point X when no signal is present. This negative voltage keeps the audio amplifier cut off so the speaker is silenced. The B+ applied to point X through the series resistor keeps the signal biased positively unless the dc amplifier is conducting. And the dc amplifier will not conduct unless there is no signal present. Or, stated more simply, the dc amplifier does not conduct when a signal is sensed by the receiver.

The audio signal from the discriminator, as previously mentioned, always bears noise unless a signal is on hand to quiet the audio line. This noise is amplified to the extent required for effective squelch action (adjusted by the squelch control), and rectified. The positive output voltage is fed to the dc amplifier along with a negative signal from the second limiter.

The second limiter grid supplies the negative signal through critical balancing resistors. The signal here is relatively stable because the limiter operates in a state of near saturation even when no carrier is present. Since the noise rectifier supplies a positive signal, the dc amplifier sees the

balanced sum of the two supply points. An imbalance exists when the noise rectifier output increases to the point that causes the dc amplifier to conduct.

The capacitors along the X line are included in most receivers to hold the squelch open for a short time after the carrier drops out. This prevents rapid on-off fluttering of the repeater transmitter when a weak station is operating on the input frequency. The squelch "tail" can be lengthened by raising the value of these capacitors (thus increasing the charge time), and almost eliminated completely by removing them altogether.

Getting a transmitter to turn on and off in response to an incoming signal is simply a matter of applying the squelch principle to an additional stage. The carrier-operated relay schematic shown in **Fig. 2** is a modified version of the type GE used on its nontransistorized commercial repeaters, and it is perhaps the most popular single circuit in use by amateurs today.

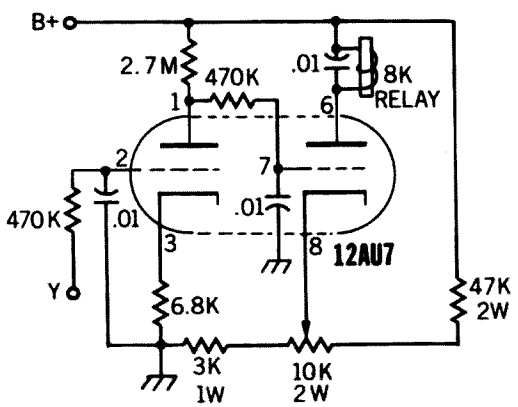

Fig. 2. Carrier operated relay.

Undoubtedly, a number of prospective repeater builders will look at the circuit and be appalled by the fact that it is not solid-state. Well, there's a good reason. Solid-state carrier-operated relays are available and easy enough to build, but the amateur world isn't quite ready for them yet. Solid-state devices require low-voltage dc; most repeaters are tube-type. And it is a lot simpler to build a tube-type relay circuit for a tube-type receiver (with its already available power supply) than it is to build a solid-state relay and be saddled with the task of building up a special power supply to drive it.

The signal input to the 12AU7 grid of **Fig. 2** is provided from the point marked Y on **Fig. 1**. The mechanical relay in the plate circuit of the second half of the tube is a current-sensitive relay with a coil resistance of 8–10 kΩ. The push-to-talk circuit of the repeater is keyed indirectly by the contacts of this relay.

The 10 kΩ pot in the cathode circuit should be rated for 2W and should be a wirewound type. This pot sets the threshold of the audio squelch.

Just one last word or two about carrier-operated repeaters: The relay shown in **Fig. 2** should never be used to perform direct switching of push-to-talk circuits. The contacts of these sensitive relays are generally quite delicate and are thus easily fouled. Regardless of a repeater's inherent simplicity, the plate relay should always be made to drive a "slave," which should be a heavy-duty type with as many contacts, both normally open and normally closed, as possible.

In one way or another, a carrier-operated relay figures into just about every automatic operation of a repeater, for active as well as passive applications. The normally closed position allows disconnection of functions during transmit, removal of voltages during control selection, and operation of timers for automatic shutdown when the repeater is unused for predetermined periods. The normally open position allows audio and push-to-talk switching, timer keying for automatic shutdown on excessively long transmissions, and initiation of functions that must occur during the presence of a carrier. To be universally applicable to any possible control function, the carrier-operated relay slave should have several sets of unused contacts in addition to contacts which provide these basic logic signals:

- Ground when signal is present on repeater input and only then.
- Control voltage available when signal is present and only then.
- Ground when no signal is present and only then.
- Control voltage available when no signal is present and only then.

EVALUATION

STANDARD SR-C-806M SOLID.STATE 2 METER NBFM 12 CHANNEL TRANSCEIVER

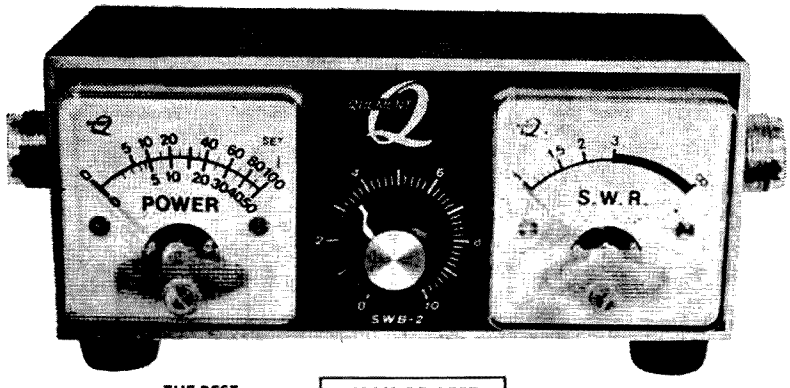
A short time ago I had a large assortment of antiquated surplus police and utility company wideband FM communication equipment. Suddenly all of this changed! I became the proud possessor of a Standard SR-C 806M 2 meter transceiver. But I'm getting ahead of myself.

My 2 meter FM activity was quite varied; mobile (repeater and simplex), base station, and a Handie-Talkie to take on frequent trips out of the immediate area. The investment in this hodgepodge of miscellaneous gear was no small amount. Nor would the size and appearance of the equipment win any beauty contests!

I was also motivated by the fact that I was about to take delivery on a new 1970 Buick Riviera. The available trunk space was ridiculously small. Dash mounting of a control head also presented serious space problems. Consequently, the introduction of the new line of completely solid state 2 meter FM transceivers for amateur use prompted me to close the obsolescence gap.

The clincher which guided me to the Standard was the 12 channel feature, the three levels of power available (with the external amplifier), and its small size and weight. The Standard SR-C 806M appeared to satisfy all of my requirements. There are several repeaters functioning in the San Francisco area and its environs. My trips take me to other areas that have repeaters operating on different frequencies. I also desired to operate "simplex" on 146.65 and 146.94 MHz and use "reversed" crystals on WB6AAE, the repeater operated by the club to which I belong. Reversed crystals are sometimes useful when the repeater is out of order or when a group is out in the "boonies" and out of range of the repeater. Consequently, my window shopping came to an end when Standard announced a ham version of its marine transceiver. (I had recently seen the Standard SR-C 801 SAR VHF rig developed for the new marine band, and was impressed with its small size, workmanship, and operating characteristics.)

I ordered the rig, hoping to coordinate its arrival with the new car. The car arrived a month after the rig, but this gave me the chance to try out my other objective; namely, to try the rig in several vehicles. I found that I could unpack it and its accessories from my attache case, plug the power cord into the cigar lighter socket, put the magnetic-base antenna on the car roof, complete the hookup and be on the air in less than five minutes!



I went "whole hog" by also getting the ac power supply and the 25W rf amplifier. The rig came with a microphone and connecting cables. The price of the rig also included crystals for four channels. I also ordered crystals for the out-of-town repeaters and had jumpers put in to provide other input/output combinations without the need for additional crystals. This is easy to arrange by using the same crystal for more than one channel "pair."

The semipermanent installation in the new car took a little longer. I had forgotten that I had ordered a tape deck stereo. This precluded mounting the rig under the dash. The size of the rig is 2¼"H x 6"W x 9"D

"Northern California's Most Complete Ham Store"

and weighs in at just over 4 lb. The obvious place was under the tape deck and attached to the "hump." The shop foreman where I work helped build the custom mount shown in the photo. The external power amplifier was tucked under the dash but out of the direct blast from the heater ducts. A GAM type TG-2R antenna was mounted near the leading edge of the trunk lid. The deck area immediately behind the window was not accessible because of the rear window ventilation equipment and ductwork. The encoder and tone burst control was placed in the mike line. Standard provided me with extra plug and socket which I wired into the tone box. This permits the option of plugging the mike into either the tone box or directly into the rig. A simple modification to the rig provided the optional ability of automatic tone burst whenever the transmit key is depressed. There is a fourth wire in the mike receptacle to bring the receiver audio out for the handset option. Since I do not use a handset, I used this terminal for the "switched on B+" necessary to operate the automatic tone burst.

The internal 2½ in. speaker is a square type with exceptionally good audio. I also have the 4 x 6 in. oval speaker for shack use. When the latter is plugged in, the internal speaker is muted. The small speaker has plenty of output to fill the car with easy copy.

I have had some difficulty with alternator whine getting into the transmitter

DAYTON HAMVENTION
Saturday, April 25, 1970

Dayton Amateur Radio Association
Dept. S : Box 44 Dayton, Ohio 45401

and going out on the air along with the audio. This appears to be a function of the car being used and how hard the alternator is working. Standard is coming out with a filter to go in the supply line but I have not seen it yet.

Standard's SR-CL25 power amplifier has been very useful when operating in fringe areas. Whenever someone reports that my signal is a little "scratchy," I boost the power to the top and become full quieting. It was also interesting to see how often I could drop the power to the 800 mW output position and still be heard!

The receiver has been excellent in its operation. The published specs on this rig stated a 0.3 μV threshold sensitivity, and the results bear this out! Squelch action is also good. If I did not want to listen to the ragged edge I would tighten it a little, thereby raising the threshold, and eliminate the squelch scratch.

The operational manual has been a problem because it is written in Japanese. The phonetic characters (Katakana and Hirugana) I could translate because I was a "guest" of the emperor for three years during WW2. The Kanji or picture language was too much for my meager knowledge of their language. Standard has informed me that there will be an English translation available at about the time this article appears in print.

The control knobs are a little crowded. I have had some difficulty turning the channel selector knob because of its proximity to the mike jack. Two sets of pressure transfer numbers were provided to identify the channels. I preferred to mark the channels with the large numbers 1 through 12 rather than the very small numbers which post the frequencies in MHz. The large channel numbers can be easily seen while mobiling whereas the small frequency numbers are too small to see at arm length. A quick glance while driving is all that is needed to know what channel is being monitored. In almost no time I was able to remember which channel did what. Also, if I ever change the relative location of the crystals or add more to work other frequencies I will never have to touch the channel selector dial.

Warranty. So far it has been good. I have had some problems but that is understandable because the serial number on my rig is # 001. In fact, it was somewhat of a prototype or engineering model. After about 6 weeks of fairly rugged use the 10W power level became inoperative. It was quickly repaired by the local rep. Later on, the power selector switch developed a problem in that it would not properly shunt out the limiting resistor which was the method used to raise the power from 0.8 to 10 watts. I recommended to the factory rep that Standard install a "dump rectifier" to limit arcing at the switch contact in case power level was changed during transmissions. So far, I can say that the warranty has been backed with satisfaction.

Overall satisfaction. For my purposes the rig has come up to my expectations. With my other rigs I was unable to transmit or receive from many locations. These areas are now solid copy. For example, "Zero Microvolt Valley" just north of San Rafael, Calif. provided a challenge for my rig which was clearly conquered. A large traffic tunnel which used to be a total blackout for me now provides good two-way coverage; I can copy throughout its length and be heard by the repeater except for a few hundred feet at dead center.

This article does not take the space to list the information on the manufacturer's data sheets or specifications. These can be obtained from Standard Communications Corp. or its local representatives.

5/8 wave mobile antenna for 2 meter FM

Gilbert Boelke W2EUP
505 Main Street
West Seneca NY 14224

In the Buffalo area, this antenna has held the FM mobile gain record since 1967.

A few years ago, a group of the Buffalo FM mobile enthusiasts ran some comparative tests with different types of mobile antennas. This article describes our testing procedures, gives the results, and describes an improved version of the 5/8-wave antenna.

Horizontal vs Vertical Polarization

As long as antenna polarization is matched at opposite ends of a path, there is little to choose between horizontal and vertical propagation. Although man-made noise pickup is higher on a vertically polarized receiving antenna, the inherent noise rejection afforded by FM tends to offset this disadvantage. The big advantage in going vertical for mobile operation is that antennas with substantial gain can be built with reasonable size and neat appearance. Fortunately, vertical polarization has been standardized for channelized FM communication.

Table I shows relative antenna gain, referenced against a dipole, illustrating the gain advantage. Gain figures were obtained in the literature cited in the first four references at

Table I. Relative gains of various antennas under ideal conditions. All verticals measured over a perfectly conducting ground plane.

TYPE	POLARIZATION	GAIN[1]	GAIN[2]	COMPARATIVE POWER
1/2λ dipole	horizontal	0 dB	0 dB	100W
1/4λ whip	vertical	0	0	100
1/2λ whip	vertical	+1.8	+3.6	44
5/8λ whip	vertical	+3	+6	25
3/4λ whip	vertical	-1	-2	160
Big Wheel	horizontal	0	0	100
Turnstile	horizontal	-3	-6	400
Halo	horizontal	-2 to -4	-4 to -8	250 to 630W
7/8λ phased	vertical	+4.2	+8.4	14.5W

[1] Test antenna at one end of path.
[2] Test antenna at both ends of path.

the end of this article, except for the 7/8-wave phased vertical, which was measured against a 5/8-wave antenna. Just to emphasize the effect on mobile-to-mobile operation, the fourth column in Table I shows the relative performance when both stations use the same antenna type. The last column converts the relative gain figures to power levels, indicating the power each station would need to realize the same signal-to-noise ratio for the different antennas, referenced to 100W using dipoles.

It must be recognized that there are gain variations —depending upon the shape of the car body, the position in which the antenna is mounted, and the direction of measurement. Our tests tended to verify the handbook figures except in the case of the 3/4-wave whip. Theoretically, the gain of this antenna at the horizon should be about 1 dB below a ¼-wave whip, but in the tests it proved to be almost the equal of the 5/8-wave whip. This anomaly is attributed to the fact that the car body is not really a flat infinitely conducting ground plane. It might be interesting to see how it behaves when located at the center of the roof, a test we did not conduct.

We tested 1/4–, 5/8–, and 3/4–wave whips, two phased collinears of different types, and the 7/8-wave phased antenna to be described. In the listening tests, two antennas were mounted on the same car on opposite sides or on cowl and roof, etc. A coaxial relay was used to switch between them. Testing operators would switch antennas while in motion, saying "antenna A," then switching to the other antenna, saying "antenna B" many times in rapid succession. On the average, a clear difference could be discerned between antennas, despite the fact that for each individual comparison either antenna might have shown up better.

The cars were driven in all directions relative to the receiving sites in average terrain in western New York.

Receiving stations were not told what antennas they were hearing or which was which. Even on the same pair of antennas, the letter designations were sometimes scrambled to prevent any possibility of prejudiced responses due to psychological fixation. It was most impressive to find that the reporting station operators could not find any difference between two identical antennas tested as a control.

Each antenna was carefully matched for a 1:1 swr, and the feedlines were cut to the same length, except in the roof-mounted installations. In this case 5 additional feet of RG-58/U cable were deliberately included, since the extra line is needed anyway in a practical installation. A 5 ft length of RG-58/U coax exhibits a loss of about ½ dB (depending upon age) at 147 MHz. This difference could account for the fact that the 5/8-wave antenna behaved identically on the roof and the cowl.

Table II lists the tests and the results. It was concluded that the 5/8-wave antenna offered the best performance. It is also one of the easiest antennas to build. The other

Table II. Test results (in order of decreasing effectiveness).

ANTENNA TYPES COMPARED AND MOUNTING LOCATIONS	TEST CRITERION	RESULTS
7/8λ phased on cowl vs 5/8 on same mount	Measurement	7/8λ shows 1.2 dB more gain
5/8λ on one cowl vs 5/8 other cowl	Listening test	No difference
5/8λ cowl vs 5/8 on roof	Listening test	No difference
5/8λ on one cowl vs 3/4 on other cowl	Listening test	5/8λ has slight edge
5/8λ on cowl vs 1/4 on roof	Listening test	5/8λ superior
1/4λ on roof vs 1/4 on cowl	Listening test	Roof mount superior
5/8λ on cowl vs 3 el. collinear on other cowl	Listening test	5/8λ better
3 el. collinear vs 1/4λ on roof	Listening test	Collinear better

collinears had the same performance, so only one collinear is mentioned. In one case it turned out that the power loss in the collinear partly offset its gain, since it heated up when appreciable power was applied.

The 7/8-wave phased antenna came about as an attempt to improve on the 5/8. It was reasoned that the 5/8-wave antenna was not the maximum length that could be tolerated on a car, and that making it longer must make it better, if only the current flow could be maintained in the same direction throughout its length. Current distributions are shown in Fig. 1 for a 5/8-wave, a

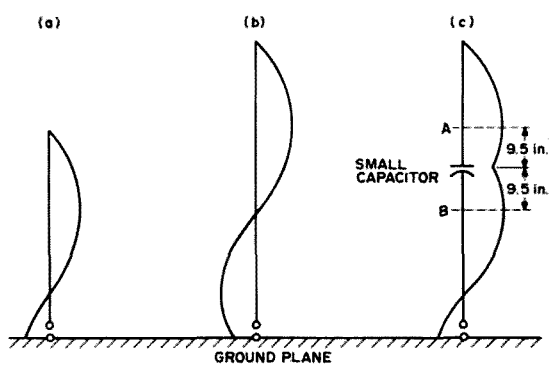

Fig. 1. Current distributions of 5/8-wave whip (a), and 7/8-wave whip (b). A series capacitance 3/8 wavelength from the top changes the current distribution as shown in (c).

continuous 7/8-wave whip, and the modified current distribution resulting from the insertion of a series capacitance at a point 3/8 wavelength from the top. The capacitor method of phasing meets the conditions of simplicity and efficiency.

An antenna of this type was constructed and adjusted to exhibit the current distribution shown. It was found that the feedpoint impedance was little changed from the standard 5/8-wave antenna. Because of this similarity, a different test method was used to evaluate it in an effort to obtain a quantitative comparison.

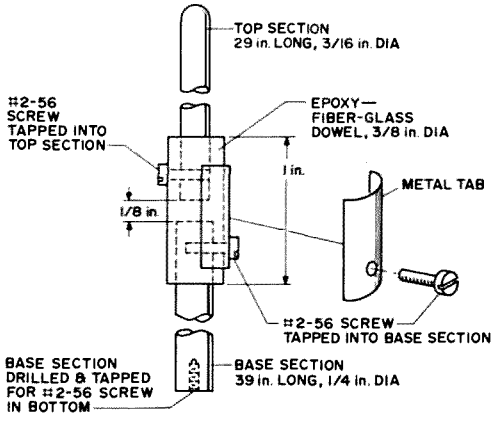
A 5/8-wave whip was installed in the test position on the car. The matching L section was adjusted to null out any reflected power and the power level to the antenna was adjusted to exactly 20W. Signal strength was noted on a meter at a station about 7 miles away. The 5/8-wave antenna was removed and the 7/8-wave antenna was substituted. The L network was then trimmed to null out some slight reflected power. Received signal strength was reported to be higher! Power was then reduced in small steps until the received signal strength was exactly the same as it was with the 5/8-wave antenna with 20W. The power then read 15.1W – for a difference of 1.2 dB. This procedure was repeated with the car moved to another spot. This time the power had come down to 14.8W, for a difference of 1.3 dB.

Other tests were made to determine whether the capacitance value was optimum, verifying that it was. If it is assumed that the

published value for a 5/8-wave antenna (3 dB gain) is valid, the gain of the 7/8-wave job must be at least 4 dB!

Construction

My antenna consists of a 39 in. length of ¼ in. diameter Dural rod for the base section, and a 29 in. length of 3/16 in. Dural rod as a top section. The two sections are joined with a piece of 3/8 in. diameter



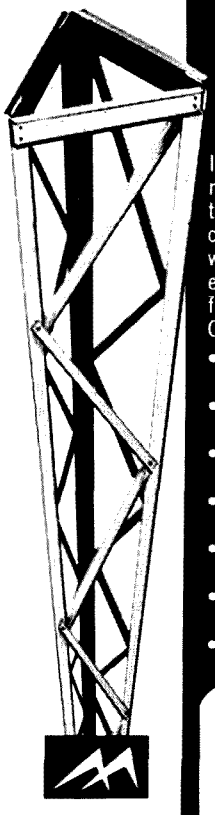


Fig. 2.

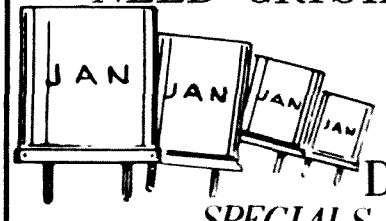
epoxy–fiberglass rod as shown in Fig. 2. A small metal tab is fastened under the screw connecting to the bottom section, and is trimmed to obtain the proper amount of capacitance between the top and bottom sections. Epoxy is used to hold the parts together rigidly and permanently.

The base mount consists of a high-voltage potentiometer-insulating fitting, made of epoxy–fiberglass with a ¼ in. shaft bushing on one end and a shaft lock on the other. Clamping the shaft lock on the base section holds the base of the antenna in place. Removal is quick and easy by loosening the shaft lock. Connection to the base section is accomplished by attaching a short Teflon-insulated wire to the end of the base section by means of a #2–56 screw tapped into the end. This wire is stripped and tinned on the bottom and a small alligator clip is used to connect into the matching network.

Impedance Matching

Due to the similarity to the 5/8-wave antenna, this antenna can be matched with a coil at the base as indicated in previous articles (Ref. 5). However, for the most accurate match, an adjustable matching network at the base of the antenna inside the

AL SERIES ALUMINUM TOWERS for uhf - vhf



Ideal for mounting industrial, commercial, citizens band, amateur, or television receiving antennas. Exceptional strength in proportion to weight qualities. Easy access to equipment mounted on the Microflect top mast extension.
Other features are:

- 10 to 120 feet high in easy to erect 10 foot sections.
- Available factory assembled or in kit form.
- Lightweight all aluminum 10 foot sections weigh only 12½ lbs.
- Low maintenance, will never rust or require painting.
- Staggered ladder treads for easy climbing.
- Can be used for direct radiator at HF.
- Wide variety of mounting brackets and accessories available

car offers three advantages: (1) Extra selectivity is added to the antenna system, minimizing interference problems on both receive and transmit; (2) other antennas may be substituted on the same mount and brought to a match with little trouble; (3) the system can be accurately matched to 1:1 SWR.

A schematic and a sketch showing a suggested construction and mounting method are shown in Figs. 3 and 4. Each trimmer is adjusted for minimum swr alternately until an exact match is obtained. If C1 reaches minimum capacitance before a match is achieved, reduce the inductance of L1 slightly. If more than half the capacitance of C1 is used at the null point, increase L until it tunes near minimum capacitance.

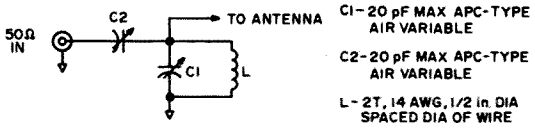

Fig. 3.

This procedure assures maximum coupling efficiency.

Adjustment of Current Distribution

Feed at least 20 or 30W of rf to the antenna, adjusting for an impedance match as outlined. Hold a neon bulb against the tip of the antenna until it fires, then slowly slide it down the top section. Exactly ¼ wave from the top (19 in.) it should go dim or

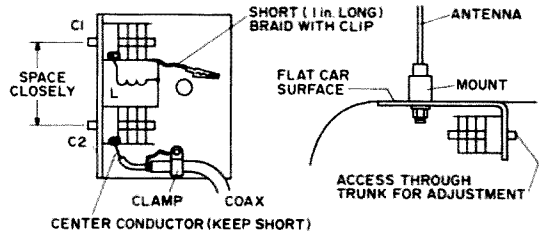

Fig. 4.

out. Continuing on down, it gets brighter at the top of the capacitor. Below the capacitor another null should be found. The position of this null moves up if the capacitance is increased, and down if it is decreased. Point B in Fig. 1c is the proper position for this null. If it is too high, reduce the capacitance in small steps by trimming the metal tab on the insulator with a pair of tin snips. As the null moves down it tends to get broader and less distinct. If doubt exists about its position, attach a paper clip to the tab to move it up to where you can see it. Then reduce

A base mount was fashioned using a high voltage potentiometer mount from an old oscilloscope.

capacitance slowly, observing the null carefully as you go. When the proper adjustment is found, epoxy the rods, the tab, and tape up the insulator.

HOW DO HAM RADIO STORES DECIDE THEIR TRADE-IN FIGURES?

Stellar Industries gives a "from the horse's mouth" rundown on the way prices are figured in the ham business.

In a letter to the editor of this magazine published in the November 1969 issue, W4GJW suggested several topics for articles for the magazine. The subject of this article is one of those suggested. Some members of the ham fraternity seem to want to know how ham equipment dealers arrive at trade-in allowances, and as a ham equipment dealer myself, I will try to answer the questions that arise. The procedure that is followed in my organization may not be precisely the same as that followed by others, but I imagine it is fairly typical.

First of all, it is necessary that we make a few assumptions. Primary among these is that the dealer has to have a potential resale market for the item or items. Consequently, in order for this market to exist, in most cases the equipment must be in working order. Most reliable dealers recondition all the used equipment they take in, in order to insure that it is working. Occasionally, it is not worthwhile to recondition a piece of equipment. When that happens, the dealer sells it at a reduced price "as is." Naturally, if a piece of equipment has to be sold "as is" the trade-in allowance cannot be as great as when the equipment needs very little reconditioning. Of course, the cost to the dealer to do the reconditioning must be taken into account in figuring the allowance, too.

Generally speaking, a given piece of equipment to be traded in, if it is in reasonably good condition, will bring approximately the same dollar value to the customer in his allowance, no matter what

new piece of gear is purchased. However, in extreme cases, pricewise, there will be some upward or downward adjustment in the allowance. I will cite an example that, in itself, is extreme, but will serve to illustrate the point. If you have an old receiver that is worth, on the average, $75.00 on a trade-in, and you decided to trade it for a complete Collins S line, selling for around $2,000.00, the dealer would probably up the allowance to around $100.00 or more. On the other hand, if you wanted to buy a $100.00 power supply, the allowance would drop down to around $50.00. Furthermore, if all you wanted to buy was a $60.00 preamp, it wouldn't be worth your while or the dealer's to even consider a trade.

The way my firm operates in figuring trade-in allowances is to follow roughly the procedure I am going to outline. First, we determine the price we think we can sell the unit for if it is in good condition. This figure is arrived at by looking at our own prior experience with the same or similar equipment. and also making reference to the prices charged for this used equipment by other dealers. Incidentally, most of the major suppliers who advertise in 73 have a relatively current used equipment list available for the asking. Next, we try to estimate the cost of reconditioning. If this cost is extremely high (such as in the case of extremely old items with hard-to-get parts) we usually plan to resell the merchandise "as is." Third, we make an educated guess about how long the used equipment will remain on our shelves before it is sold. The longer it remains in the inventory, the less salable it becomes and storage costs are a part of our overhead, of course.

Obviously, we are in business to make money, overall. Contrary to what some customers, who consider themselves sharp traders, may feel, we don't make a bundle on ham gear – new or used. In fact, in figuring trade-ins, we calculate all the factors mentioned above, and make the allowance based on a break-even figure. Our reason for this is that we plan to make our profit on new equipment and give trade-in allowances primarily as a service to our customers. As a matter of fact, if we cut allowances to a point where we could make a reasonable profit on used gear, we wouldn't have any used gear to sell. Our customers would find it more to their advantage to sell the old equipment on their own and pay cash for the new equipment, and in some cases this is the best way for all concerned anyway.

To pin trade-ins down to a percentage figure, I would say that, on the average, our trade-in allowances would be 75 to 80 percent of the price for which we hope to resell the gear. So you see, your friendly neighborhood ham dealer is neither "out to get you," nor to lose his own shirt being nice to you; but he is merely operating under normal good business practices.

While we're on the subject, this might be a good time to say a few words about used ham gear in general. Those of you who are oldtimers in ham radio don't really need to be told much, but some of the newcomers coming along undoubtedly wonder whether to invest their hard-earned money in used equipment, or wait that much longer until they can afford the new. Many good bargains can be found if you shop around. A wide range of equipment is available from World War II vintage "boat anchors" to some of the most up-to-date sideband transceivers. Of course, some of the real old stuff won't get on SSB, but with a bit of resurgence in CW work that has come about since incentive licensing went into effect, a lot of it can be quite useful. Of course, the lower power transmitters and older receivers are excellent beginners' rigs for young Novices with limited financial resources. Probably the two cautions which should be noted most in buying used ham gear are: First, buy from a reputable dealer or individual whom you know, and second, look over the wiring carefully when considering used kit-built equipment. Other than that, the world of used ham equipment can open up all sorts of possibilities for you. In fact, some people feel the same way about used ham equipment that they or others do about used cars: Let someone else work the bugs out and get hit with the rapid depreciation for the first year or two.

BERYLLIA

The Lethal Refractory

J. K. Bach WB2PAP
Ivy Hill Road
Walden NY 12586

Take another look at those tube boxes on your shelf.
Those ceramic jobs that are made with beryllia could be dynamite.

In the near future you are going to see ceramic-insulated vacuum tubes with the following notice on the carton, or on the tube, or both: "WARNING–BERYLLIA–POISON–DISCARD–SAFELY!!" What does it mean?

It means exactly what it says. The ceramic, or more properly *refractory*, is beryllium oxide, and it looks like any other ceramic: white, opaque, textured like an eggshell, not shiny, and hard enough to scratch glass. Yes, it is poisonous–*very* poisonous–but after fabrication is amply safe to use.

But children have a devilish ingenuity when it comes to smashing things, and their own reasons for doing the unthinkable. If a child or an uninformed adult got his hands on a discarded tube of this sort–! He might fracture it and cut himself on a shard of the material, thus getting particles into his blood stream. He could be in serious trouble. Or if he ingested the particles on his luncheon sandwich, say, he certainly *would* be in trouble. If any of it powdered and he inhaled even a small quantity, he very probably would die unless he got immediate medical help. The powder has the same effect on the lungs as phosgene, one of the basic war gases.

Exactly how poisonous is it? What is the exact fatal dose? Odd as it might seem, nobody knows–though it is at *least* as poisonous as arsenic, and perhaps much more so. The reason is that some people are unusually susceptible to a certain poison, while others are nearly immune to what would ordinarily be a fatal dose. Arsenic is a very good example of this–the fatal dose is given as more than so much and less that such-and-such. But peasants in Tyrol and in Syria practice arsenicophagy, which is salting food with scrapings from their chimney flues, which contain an arsenic compound deposited there by burned fuel. The practice is illegal, but they have done it for generations and will probably continue. Arsenic has been prescribed from the earliest times for skin ailments. And those Tyroleans do have beautiful clear skin! The Borgias used arsenic in their brand of politics, and it is still used in medicine. Mountain climbers take a tiny amount to increase their resistance to fatigue. And at one time a Swedish chemical plant sunk excess arsenic in the ocean to get rid of it. Sound familiar?

But beryllium is a different cat altogether. It is not used in medicine in any amount or form. It finds more uses in industry every day; airframes for high-speed aircraft, moderators for nuclear reactors, windows for X-ray tubes, as well as an alloying element for many metals, principally but not exclusively copper. This last

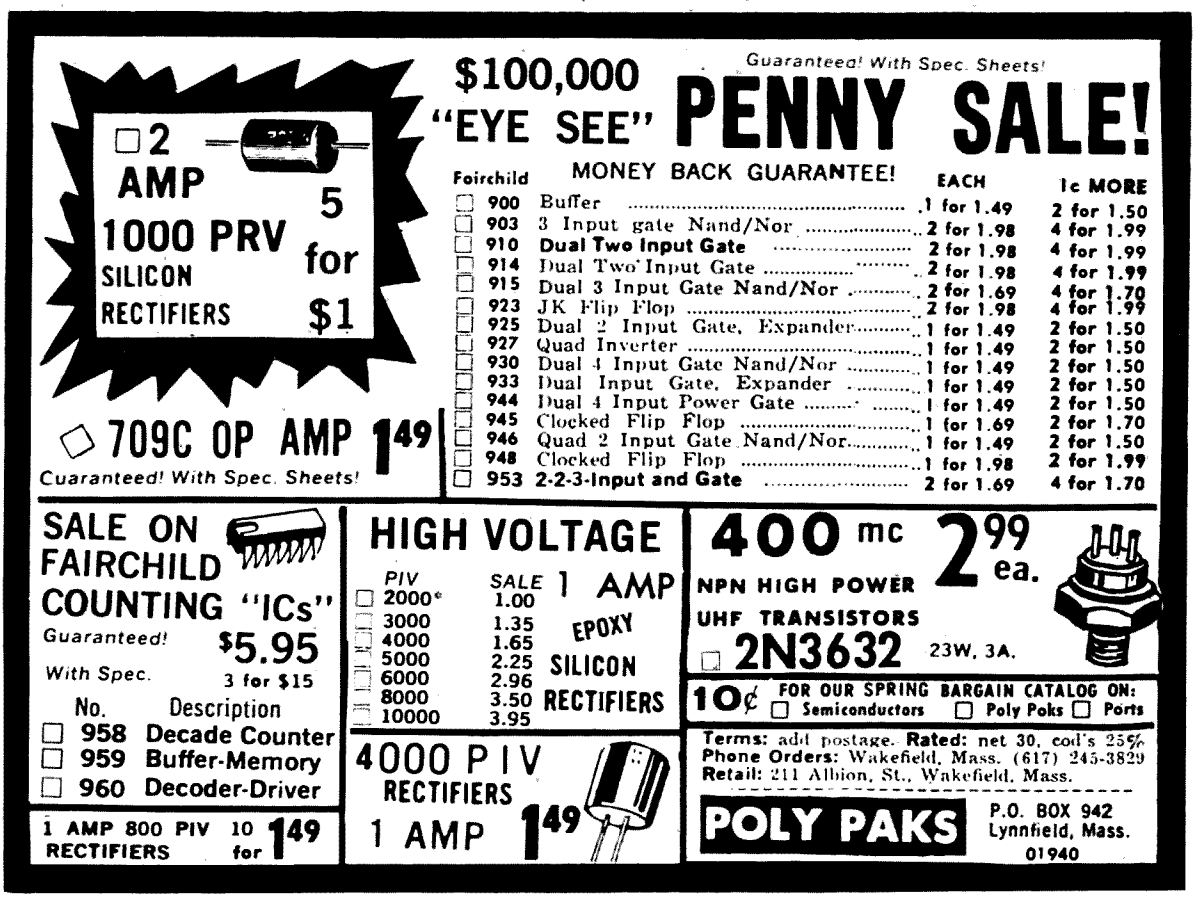
we all know–2% beryllium and the copper spring never breaks. Hazard? Not after fabrication.

Beryllium is not simply an irritant–industrial safety men claim that it is a "protein poison" which in some way poisons the body cells directly. It finds its way into the bone marrow, where it affects the hemoglobin. Once in the body, it is eliminated very slowly, and it causes damage to the lymph nodes and the liver. It produces granulomas, which are grainy tumors. Convinced?

Inhalation of the dust is by far the most serious hazard; introduction by ingestion or puncture is comparatively rare. After manufacture, powdering the stuff would be fairly difficult, though children and some adults might manage it. If you think it's easy, try it on an ordinary porcelain insulator! So while the hazard is fearfully real, it is remote so long as you treat it with the same respect afforded arsenic, cyanide, or radioactive substances. I don't like radiation either, but I don't hesitate to wear a luminous-dial wristwatch. Knowledge is safety, ignorance is danger.

And speaking of ignorance–remember the warnings about the original fluorescent lamps? Did you take them seriously? I didn't! Oh, I knew that the stuff was probably irritating, but it never occurred to me that a little powdered phosphor from just one broken lamp could kill me. That phosphor was beryl zinc silicate, no longer used. After lawsuits and investigations, the maximum safe dust contamination was determined to be from one to two (that *spread* again!) *micrograms* per cubic meter! I'm sorry, but today this sounds like fresh, pure mountain air to me.

So what *is* beryllium, exactly? It is a light metal, brother to aluminum, but it melts at a much higher temperature, 1284 degrees C. It conducts electricity about a third as well as copper and is a good heat conductor. It is not ductile and is difficult to form into sheets. A billet of beryllium costs from $50 to $100 per *pound*, and if you want the 100-proof stuff it will set you back $2700 per pound. When shipped, it must by law bear a poison label. Chemical handbooks warn you not to taste even the smallest quantity of any beryllium compound to see if it is really sweet, but to just take their word for it. Chemists used to do this. The original name for the metal was glucinium, from glucose, a sugar.



You wouldn't do anything so foolish? I hope not. Once I had a refrigerator that released a quantity of sulfur dioxide gas in my apartment–smelled like a chicken house. When I got through coughing, I moved back in and breathed residual gas absorbed by drapes, bedding and rugs. I would have done much better camping in the street–I had bowel and stomach upsets that persisted for well over a year. But I have learned from the experience. Now when a selenium rectifier stack breaks down and stinks up the place, I'm the first one out of the room. Selenium in the ground is absorbed by growing grass which is eaten by cattle which abort and breed monsters ("selenism") and poisons people who consume the meat and milk. A brother to sulfur, it's poisonous enough, but not in a class with our new friend.

So why use the damned stuff? First, it is perfectly safe if treated intelligently. The second reason is that it will make possible a new breed of high-power, high-frequency, high-performance tube.

Combine beryllium with oxygen, BeO, and the conductivity for electricity drops to zero, since there are now no unbonded electrons. But the heat conductivity which is pretty good for a metal is utterly *fantastic** for a refractory, and the melting-point is practically doubled: 2450°C. Red heat is only a little more than 1000°C. The low coefficient of expansion helps too, but the heat conductivity is the real reason that tube men are getting excited over its possibilities. They don't care how hot the refractory gets so long as the seal holds, but if the heat can be readily conducted through it (imagine!) the other electrodes will run cooler, or dissipate larger amounts of power, or both. At high frequencies where tube capacitances are a vital factor, a 'notter," smaller tube is possible.

So you use an 807 or 6146? Fine! They don't have or need beryllia. But you may

*Twenty times that of quartz, 62% that of copper, and even higher than metallic aluminum, which is only 55%. Fantastic is right!

wind up in a broadcast station which does use the new tubes, and you will then need to know how to handle them. Which is, with the same care you use with *any* tube. The stony stuff won't rub off on your hands; no amount of handling or exposure could possibly affect you. It must at all costs be kept out of your body in *any* quantity! If you handled a broken tube as if it were radioactive, that would be about it. Make sure that all the big pieces are collected. Then get up the smallest fragments—use a rag made tacky with shellac, varnish, grease, whatever will work. If the tube was really crushed, beware dust—turn up the airconditioning, or open windows and doors, and stay clear until you are sure it has dissipated. Put the fragments together with the tack-rag into a plastic bag, and make plans to return the package to the manufacturer, or to bury it in the back yard.

If you get a sliver in your skin, remove it completely, *make the wound bleed* by *gently* squeezing it to flush out any particles remaining, and consult a doctor at once. Probably you are in no danger, but why take a chance? Feeling foolish is better than feeling dead.

You have got a new tube that maybe has beryllia insulators? Send now to know which types have it; if it ain't on the carton, they will not tell thee. Appearance means nothing but heat conductivity does. Put a soldering iron on the plate and a finger on the grid ring. With glass or ceramic, you can hold it there a long time. If you have to remove the finger almost immediately, you have beryllia there. The stuff is unique—it couldn't be anything else if it is a good insulator and a good heat conductor in thick sections. If you have beryllia, treat it with respect and you will be perfectly safe.

Beryllium. Beryllia. What makes the name so familiar? Beryllium copper? Maybe, but nature makes a compound of beryllium:

$$Be_3Al_2(SiO_3)_6$$

occurring in hexagonal crystals of almost unlimited size, with various hues due to trace impurities. These are called beryl and are semiprecious stones. But if the stone is perfect, and you have just the right amount of chromium in your beryl, you have a natural emerald!

Getting Your Extra Class License

Part XV: Spurious Radiation

Amateur radio operators operate radio transmitters.

This may sound like an obvious observation, but it implies directly that *good* amateur radio operators operate their transmitters well—and that means that they must know *how* to operate them. Consequently, the FCC examination for the Extra Class license contains a heavy proportion (1/9 of all the questions on the study list cover this subject) of items intended to test the applicant's knowledge of transmitter operation.

Because of the number of questions and the many items contained in them, we'll devote not one but two sections of this study course to the subject of transmitter operation. This time, we'll deal with the following questions from the FCC study list:

53. How can a transmitter be tested for self- oscillation? What precautions should be observed during testing?

72. What radiotelephone transmitter operating deficiencies may be indicated by a decreasing antenna rf current during modulation of the final rf amplifier?

75. What may be the cause of a decrease in antenna current during modulation of a class B rf amplifier?

77. How can parasitic oscillations be prevented?

87. How can the final amplifier of a transmitter be tested for self-oscillation?

As usual, we won't attempt to deal directly with these specific questions. Instead, we'll rephrase them into more general queries, covering the same subjects but in broader scope.

These five specific questions divide into two broad groups, one dealing with self-oscillation and other spurious signals in a transmitter and the other dealing with problems during modulation. Let's break each of these groups up into a couple of questions to aim at the major subjects.

First, let's find out "What are the causes of spurious signals?" such as self-oscillation and parasitics. Then let's ask "How can we find and fix spurious-signal problems?" That should take care of questions 53, 77, and 87 adequately.

Turning to modulation problems, let's find out "What does antenna current tell us about modulation quality?", and then move on to ask "What causes modulation problems?" Having found out the probable causes we can ask finally "How can modulation troubles be cured?"

That should be enough to take care of us for one chapter. Ready to start?

What Are The Causes of Spurious Signals? Ideally, the output of a radio transmitter should consist of only a single signal (which may be merely a carrier, one or two sidebands only, or a carrier plus sidebands). Normally, any signals in the output which are *not* an integral part of this single desired signal are called "spurious" signals.

Thus the list of possible spurious signals includes harmonics, modulation distortion products, parasitics, and off-frequency signals such as those generated by self-oscillation of one or more amplifiers in the transmitter.

Since we're going to deal with several questions concerning harmonics in the next

installment of this course, we'll leave them out right here. Similarly, we won't concern ourselves too much with buckshot, splatter, and other modulation-connected spurious signals, since we'll meet them later in this installment. The major types of spurious signals left for us to examine here, then, are those caused by parasitics, and those caused by self-oscillation.

Actually, parasitics are only a special type of self-oscillation, and the causes for both are extremely similar. The major difference between a "parasitic" oscillation and the condition usually called "self-oscillation" is that a parasitic occurs at a frequency far removed from the intended operating frequency of the transmitter, while "self-oscillation" occurs at or near the intended operating frequency.

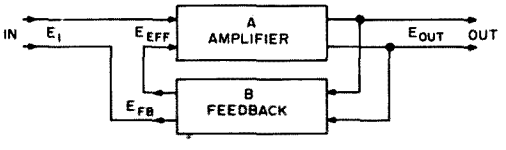

Fig. 1. Oscillation criterion depends upon both loop gain and phase shift of feedback as shown here. If quantity (1-GAINB) is equal to zero, effective gain becomes infinite and circuit will provide output with no input; this is the definition of an oscillator. Any time that this condition is satisfied, a circuit must oscillate. If it is not satisfied, oscillation is not possible.

There is, of course, only one possible cause for any kind of oscillation, if we go far enough down toward the basics of theory, and that is the fact that a closed feedback loop exists with a phase shift around the loop of zero degrees and a loop gain equal to or greater than one. This pair of conditions—unity loop gain and zero phase shift—are known as "Barkhausen's criterion" for oscillation, and unless both conditions are present oscillation cannot exist.

Unfortunately, this basic cause is so basic that it doesn't help us much in many practical instances. The feedback loop in any practical transmitter is almost always accidental; it may be due to stray magnetic coupling, to lack of shielding at some critical location (which usually does not appear to be critical for any obvious reasons), or even due to reradiation of some of an amplifier's output through power-supply leads.

If the spurious signal is near the intended operating frequency, and so falls into the category of "self-oscillation," the cause is probably directly due to an unintentional feedback path from output to some earlier stage. This feedback need not be from the actual transmitter output stage; it may be from the output of any earlier stage to that same stage's input or to any lower-level stage.

The most common causes for this type of problem are stray coupling between resonant circuits in different stages, feedback through power-supply leads, and feedback through the tubes or transistors themselves. If any stage is neutralized, misadjustment of the neutralization is always a primary suspect should self-oscillation occur.

The stray coupling between resonant circuits may be either electrostatic (which means simply inadequate shielding) or electromagnetic (improper placement). Most common in homebrew rigs is electromagnetic coupling; a commercially designed transmitter seldom suffers self-oscillation unless a neutralizing adjustment is off.

Feedback through power supply leads may occur either on the high-voltage leads because of inadequate decoupling between stages, or on filament leads by pickup and reradiation.

A less common cause of self-oscillation is existence of a "ground loop," in which the ground returns for a stage are made to several different locations on the transmitter chassis. The currents flowing between the various ground points may develop enough

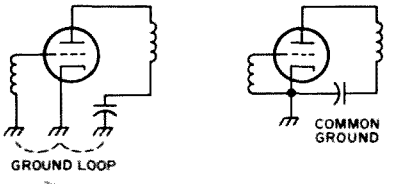

Fig. 2. Ground loop as contrasted with single-point grounding. If grid and plate currents flow exactly as shown by dotted lines at left, ground loop causes no trouble; however, if both flow through same portion of chassis, feedback may occur. For this reason single-point grounding is recommended for all construction, to prevent possibility of ground-loop occurence.

voltage to produce unwanted feedback? they may also radiate enough energy to be picked up by some lower-level stage.

Any conductor carrying a current is surrounded by a magnetic field, and so it's not possible to completely eliminate all rf feedback in any amplifier because the magnetic fields of the various conductors provide some small degree of inductive coupling between inputs and outputs.

However, proper placement of wiring can reduce this unwanted coupling to a minimum, and it's not usually a factor in self-oscillation of a well-designed transmitter or amplifier.

"Parasitic" oscillation is another case entirely. The unavoidable small coupling between conductors—both the inductive coupling we just mentioned and the equally unavoidable capacitive coupling through the air separating the conductors—means that it's always possible to get a closed feedback loop. Since the amount and type of coupling will introduce some phase shift, which will vary with frequency, it's also always possible to find some frequency at which the phase shift around this closed loop is zero. And that means that one of the two conditions required for oscillation can always be met. If anything permits the other condition to also be met, oscillation is unavoidable—and that's where parasitics come from.

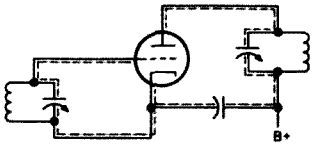

Fig. 3. This simplified schematic shows how parasitics happen. Solid lines show expected flow of signal current through entire resonant circuit. At some high frequency, though, inductors of resonant circuits act as chokes, and self-inductance of connecting leads shown in dotted lines provides a substitute for the coils so that another resonance occurs. Circuit then acts like tune-plate-tuned-grid oscillator at this higher frequency. Suppressors kill parasitics by loading down the vhf resonance while leaving the desired tuned circuits alone.

For any amplifier to produce gain, it must work into a load impedance. In general, a vacuum-tube amplifier will produce a gain which is directly related to the value of the load impedance; the higher the impedance (within limits), the greater the gain.

The designer of an rf amplifier almost always intends that the amplifier be operated at only one frequency at any given time. He designs the circuit to provide the desired load impedance at only that frequency. The amplifier stage may still have gain at other frequencies—particularly frequencies close to the operating frequency—but not as much. And at frequencies far removed from the operating frequency, the load impedance is supposed to be virtually zero, permitting no gain at all.

At the intended operating frequency, the unavoidable coupling from input to output is usually overcome by the process known as neutralization. This amounts to introduction of just enough deliberate feedback, in the opposite phase to the unwanted but inescapable stray feedback, to cancel its effects out so that the amplifier is essentially feedback-free.

A properly neutralized amplifier normally remains neutralized over approximately the same band of frequencies at which it has appreciable gain. The idea is that, for any frequency at which gain is greater than unity, the feedback be zero. If gain is less than one, the amount of feedback is immaterial insofar as the possibility of oscillation is concerned, because *both* the gain and phase conditions must be met for oscillation to occur.

Unfortunately, the intended operating frequency is usually *not* the only frequency at which an amplifier exhibits gain. While the designer may have intended for load impedance to be negligibly low at all other frequencies, the fact remains that a length of straight wire has both inductance and capacitance, and at some frequency cannot help behaving as if it were a tuned circuit.

In addition, the grid and plate structures of tubes themselves also have enough L and C to act as tuned circuits at some frequency, and the designer's carefully planned output tank circuit may exhibit resonances at more than the single frequency he intended.

At any frequency for which the impedance of these unintentional tuned circuits is sufficiently large, the amplifier will in consequence have greater than unity gain. If a zero phase shift also exists at this

frequency in the unavoidable feedback loops, oscillation must result.

We call such oscillations "parasitic" because they are like parasites; they were never planned into the scheme of things, and they can exist only when the amplifier is operating in an otherwise normal fashion.

Frequently, a parasitic may not appear when an amplifier is being tested under moderate-power conditions with a steady signal, but will blossom forth in all its obnoxiousness when full power and modulation are applied. The change in amplifier operating conditions increases gain just enough (or possibly modifies the coupling slightly) to permit the oscillation. A variation of this behavior is the type of parasitic which exists only for a few dozen cycles at the peak of each cycle of intended-frequency signal, and is absent at all other times.

In almost all cases, the cause of the parasitic is an unsuspected load impedance in the amplifier's output stage which permits amplification at unintended frequencies. Normally, the frequency of a parasitic is much higher than that at which the amplifier is intended to operate. Amplifiers intended for the 3-30 MHz range usually have VHF parasitics, VHF amplifiers exhibit UHF parasitics, and so forth.

This rule does not always hold true. In some cases, parasitics may occur at frequencies far *below* the intended operating range. The phenomenon, known as "motorboating" in af amplifiers, is typical of a lower-than-operating-frequency parasitic. It occurs when the feedback loop encompasses the entire chain of amplifiers and includes substantial time delays. This type of parasitic in rf amplifiers, occurs only rarely. When it does, the feedback path and undesired load impedance producing the unwanted gain are usually to be found in either the power supply or the power wiring, rather than in the signal circuits of any individual stage—and when these conditions exist, self-oscillation is much more likely than is a lower-frequency parasitic.

Another type of spurious signal which afflicts only radiotelephone transmitters is that produced by rf feedback into the audio circuits. This can produce symptoms very like those of parasitics. What happens is that some of the modulated rf output of the transmitter is finding its way back into the audio circuits of the modulator or preceding audio stage, and is there being detected to produce an audio signal which is a feedback signal. The feedback loop is closed by a path through the modulation process, and so both the audio and the rf signals are affected.

In addition to the fact that their radiation is illegal because of the uncontrolled interference which they cause, these spurious signals are to be avoided at all times because they can easily result in severe damage to the transmitter. Parasitics, in particular, can lead to amazingly high levels of reactive volt-amperes in even moderate-power transmitters, because the signals which are generated are predominantly confined to the transmitter (they are coupled to the antenna only by accident). The multi-kilovolt levels which result can pop coupling capacitors, melt down polystyrene coil spacers, and even vaporize tube elements by forcing the tube to improper operating points.

How Can We Find And Fix Spurious-Signal Problems? Now that we've looked at the causes of spurious-signal problems, it's time to look a little deeper and discover how to find and fix them. While there's always one easy way to find out that you have a spurious-signal problem, it's not recommended—for one thing, FCC pink slips are most upsetting to the tranquility of most of us, and while you're waiting for one to come along you may be clobbering untold QSOs or possibly even emergency traffic!

So it's best to check out any new transmitter, whether it's a homebrew rig or a store-bought outfit, to be certain that it's free of spurious signals, before ever putting it on the air.

While the checkout is a virtual necessity in the case of homebrew and kit-built equipment, it's also most important in the installation of completely factory-wired gear as well. Bad design or construction is *not* the sole reason for spurious signals, as we have seen. Misadjustment can also cause them, and even the most reputable rig *can* be misadjusted between the factory pre-shipment inspection and its arrival on your operating desk!

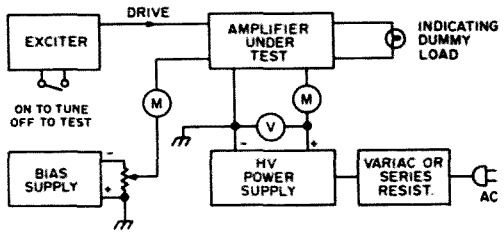

Fig. 4. This test setup can be used to test an amplifier for both self-oscillation and parasitics. Exciter is used only to provide drive while initially tuning amplifier under test. Output should disappear when exciter is switched off, and remain absent for all settings of amplifier controls. Any output indicates spurious signals; their cause should be traced out and eliminated.

The procedure in testing for self-oscillation is relatively simple. Connect the transmitter to a dummy load, preferably with some type of power indicator (a light bulb coupled to the load will suffice if nothing more exotic is available). Remove any drive by removing the crystal (don't use a vfo for the checkout). Fire up the rig, but keep plate voltage off until everything is warmed up.

Now apply plate voltage briefly and swing each tuning capacitor across its range while plate voltage is ON. You have to be fast, if the rig doesn't include fixed protective bias, to avoid tube damage due to the lack of grid bias. Any output indication at all must come from self-oscillation, since the normal oscillator stage has been disabled by removal of the crystal.

If the transmitter has many stages, it may be necessary to perform this test on only one stage at a time in order to limit the power-on time. The main thing to watch out for is permitting excessive plate current to flow for more than a very few seconds. Some of the more modern screen-grid power tubes can completely melt out their screens in less than 30 seconds under zero-bias operation!

To be absolutely safe, it's best to provide normal operating bias for each stage. This bias can be supplied from one or more small transformer-operated power supplies, adjusted to provide the desired dc output and connected to the grid of each stage through rf chokes for isolation. If this is done, keep in mind that the added grid-bias leads may, in themselves, introduce feedback unless you're extremely careful. However, with all stages properly biased, you can leave power on long enough to test all settings of the adjustments. Also, a change in bias conditions may permit oscillation during the test which would not occur during normal operation.

A quick indication of self-oscillation is the capability of tuning to a dip in final plate current at two points in the tuning range which are *not* harmonically related. Of course, if you're operating at 3.6 MHz and tune the final to 7.2 MHz you can get a dip, and this does not indicate self-oscillation. But if you get a normal dip at 3.6 MHz and, without changing frequency of the oscillator, tune a little higher to the neighborhood of 5 MHz and find another dip, this is a pretty fair indication that you have self-oscillation around either 2.5 or 5 MHz. Should this happen to you, be sure to run the full self-oscillation checkout.

Having discovered a case of self-oscillation, how do we fix it? The first step is to determine which stage in the transmitter is oscillating. If it's convenient to remove plate and screen voltage from individual stages, this is the easiest way to find out. Start at the next-to-final stage and remove both plate and screen voltage. If the oscillation is still there, it must be in the final stage alone.

If the oscillation disappears, restore power to the driver stage and remove power from the stage preceding. Reappearance of the oscillation indicates that no stage ahead of the driver is involved. To find out whether it's the combination of driver and final, or merely the driver alone, remove power from the final and couple some sort of rf indicator to the driver's output. If both stages are involved, the oscillation will disappear. If it persists, the trouble is in the driver stage only.

If the oscillations fail to reappear when power is applied to the driver, move back another stage toward the oscillator and repeat this procedure. Keep going until the trouble has been isolated to a single stage or group of stages.

CAUTION—Never remove plate voltage from a tetrode or pentode tube without also removing screen voltage. Otherwise the tube

is almost certain to be destroyed by excessive screen dissipation.

When the stage or stages have been isolated, apply the things we've already learned about the causes of self-oscillation. Look particularly for coupling between input and output circuits, and for misadjustment of any neutralization components. Also check all bypass capacitors to be certain that they're doing their job. In severe cases, it may be necessary to virtually redesign the offending stage to eliminate coupling from input to output by relocating components.

After each correction is made, repeat the test procedure to determine whether the spurious oscillation has been eliminated.

Detection and elimination of parasitics is a much more bothersome business. Most circuit designers prefer to simply assume that parasitics will be present unless they are suppressed, and design in parasitic suppressors to do away with them.

A parasitic suppressor consists, essentially, of an additional tuned circuit broadly resonant at the frequency of the anticipated parasitic, and swamped down with a composition resistor of low value to kill any effective load impedance. For tubes in the 100-watt power output class, a .47-ohm 2-watt resistor with 3 or 4 turns of wire wrapped around it does the job normally. This suppressor is connected in the plate circuit, as close as possible to the tube's plate terminal (that is, one lead of the resistor is soldered to the plate-cap clip with as short a lead as physically practical, just as bypass capacitors are installed). For higher power levels, the same idea works but higher power ratings are needed.

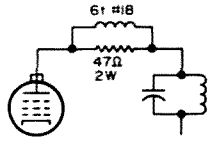

Fig. 5. Typical parasitic suppressor consists of 6 turns of number 18 wire spaced out to occupy the full length of a 47-ohm 2-watt composition resistor. This suppressor is adequate for hf rigs up to the single 6146-807-6DQ5 class; for higher power rigs, use several resistors in parallel to provide higher power capabilities. For vhf rigs, reduce coil size to 3 or 4 turns, again spaced out to full length of resistor.

The parasitic suppressor works by concentrating any stray inductance or capacitance which might form a parasitic's load impedance into a known location, and then loading that impedance down with such a low-valued resistor that its Q is far less than unity.

If, despite parasitic suppressors, you suspect that parasitics are present in a rig, perform the same test as for self-oscillation except that normal drive signal can be applied. Output at any except the oscillator frequency or a harmonic of it can be attributed to parasitics.

Probing with a neon tube can help locate parasitics, also, if (as they usually are) they happen to be VHF or UHF oscillations.

The glow of a neon tube excited by rf pickup through its glass walls is normally orange, just as is a normal neon glow. The signals produced by parasitics, however, usually make the neon glow purple rather than orange. The change in color is not due to the frequency, but to the amount of power picked up. The neon will pick up more power from a VHF or UHF signal than it will from one of lower frequency, because it is of fixed physical size and the pickup is governed by the tube's size in relation to the signal wavelength. With excessive power applied, the neon glows purple rather than orange.

Another handy guide to parasitics, surprisingly enough, is standard equipment for most operators—a pair of ears! When a parasitic is running wild in a transmitter, it frequently causes a high-pitched whining sound. It's the same phenomenon that makes a transformer with a loose core lamination "buzz" when power is applied; in the case of the parasitic, anything which may be capable of being vibrated by it is—not at the rf frequency, but at some audio subharmonic of the parasitic's actual frequency. Occasionally, too, the power unleashed by the parasitic will cause arc-over of a tuning capacitor, and this too can be heard (and seen).

If parasitics occur in a rig which has supposedly been parasitic-suppressed, suspect failure of the suppressors first. If they are all good (check by replacement), then check for presence of ground loops and especially for common impedance in both the grid and plate circuits. A few inches of hookup wire is sufficient common impedance to develop a quite respectable UHF parasitic. And in the attempt to find and fix parasitics, keep always in mind that patience is the most important parameter!

What Does Antenna Current Tell Us About Modulation Quality? While many experts will tell you—and we won't disagree—that the only way to get a really good measure of modulation quality is to use an oscilloscope and either a trapezoid (for AM) or bow-tie (for sideband) display, the fact remains that antenna current alone, as measured by either an rf ammeter, a sampling device such as an swr meter, or even a lamp bulb coupled to the transmission line, can tell quite a bit about modulation. At the very least, it can indicate the presence of some troubles which may not be so apparent in the final-amplifier plate-current readings.

The reason that the antenna current is an indicator of modulation quality is simple. Almost any kind of modulation except for FM will result in a variation of the power applied to the antenna. Since antenna impedance is relatively constant, at any one operating frequency, the only way in which the power can vary is for the voltage and current in the feedline to vary.

With normal, high-level, 100-percent AM, and a sine-wave modulating signal, the output power *with* modulation should be 1-1/2 times as great as that *without* modulation. Since the power varies as the square of the current, to obtain this 150% power variation the current must vary about 122%. That is, the power as indicated on an rf ammeter should increase by 22 percent when 100-percent sine-wave AM is applied to the signal.

Note that this figure is true only for one special case of modulation. If modulation percentage is less than 100 percent, the current increase will be less. If some process other than high-level modulation is used, the current increase may be less (although it should not be more). And if the modulation is a voice signal rather than a sine wave, anything can happen and usually does!

Because of the great variations possible when the test signal is anything other than a

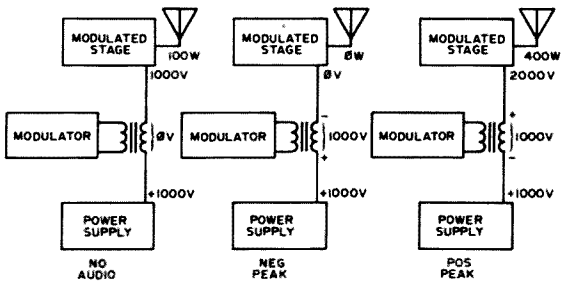

Fig. 6. Principles of high-level AM are shown here. At left, with no modulating signal, modulator output is zero volts and full voltage of power supply goes to modulated stage, providing normal output level. At center, on negative peak for 100-percent modulation, modulator output exactly cancels out power supply voltage. Modulated stage gets zero volts and output momentarily drops to zero. At right, on positive peak of signal, modulator output adds to power supply level to double voltage to amplifier and produce four-time power level. Failure to meet these conditions means modulation trouble is present.

sine wave, virtually all discussion of the effects of antenna current in modulation assumes that only sine-wave modulation is used. This turns out to be most confusing to most of us, when we attempt to put it into practice to monitor our modulation, and that's one of the reasons that the experts recommend scope monitoring—it's one of the very few forms of modulation monitoring which is equally effective on both voice and sine-wave signals.

But if we do have a sine-wave signal, as we would have if we were attempting to check out a modulator by measuring antenna current, then we can confidently look for that 22-percent increase in power when the modulation is applied.

Should the power remain constant, or decrease, it indicates something is not going right in either the modulator or the modulated stage. One possible cause of lack of power variation (constant power) might be a power-supply deficiency which reduced carrier power whenever the modulator was supplying any power. This would, of course, cause distortion by making the modulation percentage vary widely through the course of a single audio cycle.

A decrease in power or antenna current when modulation is applied, on the other hand, indicates a misadjustment of the modulated stage. Most high-level modulation schemes operate by varying the supply voltage available to the modulated amplifier. When the supply voltage is raised, the modulated stage is supposed to deliver the additional power. If its drive is insufficient, or if it is operating at the wrong point on its grid-bias curve, the additional power may not be available to be delivered. In this case, the increased supply voltage causes an actual decrease in power.

Either insufficient or excessive loading on the modulated stage, also, can cause a wrong-way power variation. We'll look at the possible causes of modulation troubles in more detail a little later; right now, the point is that failure to obtain the expected increase in antenna current does indicate problems, and may give you an idea as to the approximate type of problem which exists.

So far, we've discussed only high-level AM amplifiers. Similar reasoning applies in the case of linear amplifiers, whether they be Class A, Class AB, or Class B. When modulation is present, the antenna current readings should increase. The increase should never exceed about 22 percent from the carrier-only readings, however, with sine-wave modulation (voice may provide readings as great as twice the carrier level, in certain circumstances).

Screen-modulated stages, and those using other forms of "efficiency modulation," should also give the same normal readings. These types of modulated amplifiers, however, often exaggerate the "problem" indications of the antenna-current measurement. That is, any problem which would cause a slight decrease in antenna current with high-level modulation may cause an extreme drop in antenna current with an efficiency-modulated stage. The difference is not due to any difference in the measurement; rather, it's because these types of modulation are so much more sensitive to the particular types of problems which show up most readily in an antenna-current measurement. The degree of misadjustment which would be only negligibly off in a high-level stage may easily be intolerably out, in an efficiency modulated rig.

While the antenna current measurement can pinpoint several kinds of trouble and their probable causes, it is totally useless in

attempting to troubleshoot many other kinds of problems. For instance, antenna current cannot reveal directly the presence of distortion, nor spurious outputs such as parasitics occuring only in the presence of modulation. Neither can measurement of antenna current reveal much about sideband suppression. To spot these troubles, the scope offers the only quick way (careful probling with a selective receiver, used as a spectrum analyzer as we discussed in the previous installment, can also spot such troubles, but is much more tedious).

It's for this very reason that the measurement of antenna current has given way to scope monitoring of output, for many hams. But since the antenna current measurement *can* tell us much, and *is* one of the classic means of locating some types of modulation problems, the FCC requires that candidates for the Extra Class license know something about it. After all, a little history and tradition is just as necessary as is a knowledge of the latest state-of-the-art techniques and theories.

Now that we've seen what the antenna-current measurement can tell us about modulation quality, and what it can't, let's move on to determine the major causes of the modulation problems which our tests may reveal.

What Causes Modulation Problems? "Modulation problems" is a label covering a multitude of symptoms. In the first place, we have three distinct major types of modulation (amplitude, frequency-phase, and pulse), and a number of sub-classes within each of these types. What turns out to be a problem for one particular sub-class of one type may be desired operation for some other variety.

To illustrate this point in a bit more depth, let's look at several quick examples. If the signal's apparent center (or carrier) frequency changes when modulation is applied, is this a problem? With AM, it's a serious problem—so serious that it falls into the class of prohibited emissions! But if you're using FM, it's the desired result.

Another case: The "carrier" power level increases when modulation is applied. We're not talking about the "extra" power supplied by the modulator; we're assuming that the measurement devices are sufficiently selective to pick out only the carrier component of the output signal, and this component alone increases in strength with modulation. Is it a problem? For high-level AM it is, and we call it "carrier shift." Its presence indicates that the operating point of the modulated stage is being shifted by application of modulation, and distortion of the output signal is likely. But if we're using a controlled-carrier modulation technique, which is a common design for screen-modulation systems, then the increase of carrier power with modulation is again the desired operation.

So what is a modulation problem? Basically, it's anything connected with the production of a modulated rf signal that produces results other than those you intended to achieve.

That's such a wide field that it would take several volumes to answer our original question in complete detail for all cases. You would also get much more information than you probably will ever want about modulation problems. So for the purposes of this question, we're only going to talk about the common problems of the common types of modulation—primarily high-level AM, since we've looked at FM and sideband in other installments of this course.

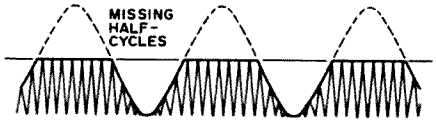
To know when we have a problem, we must first find out what results we intend to achieve when we attempt to apply high-level AM to an rf signal. Several concepts for describing the amplitude modulation process exist, and all have their uses. We can look on the process as a mixing action which translates a voice signal into the rf range, or as a control action in which the voice signal modifies the gain of an amplifier to produce a signal of constant frequency but varying strength. While the first is closer to what actually goes on, the second is often useful in examining modulation problems.

If we look on the desired output signal as being a single rf signal which varies in strength (assuming 100-percent modulation with a sine wave) from zero to double the carrier-only voltage levels, we know immediately that the modulated amplifier must be capable of putting out a voltage level at least

twice that produced in normal operation without a modulating signal.

In order to do this, the amplifier must have adequate drive available to generate the double-voltage output with no change in driving signal, and it must be working into an impedance level which will permit it to develop the double-strength output. If either of these conditions is not met, we will have a modulation problem because the output cannot do what it is expected to do.

With the most conventional form of high-level modulation, the modulating audio signal is placed in series with the dc supply to the modulated stage. If the audio signal exactly cancels out the dc supply on its negative-going peak, this will take care of reducing the output signal level to zero at that time because without plate and screen voltage, an amplifier cannot produce output.



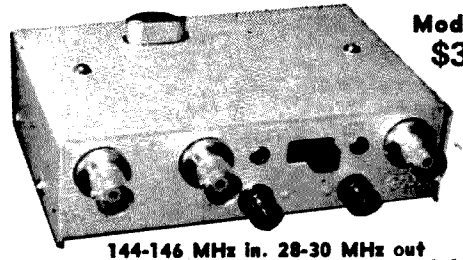


Fig. 7. If modulated stage is unable for any reason to increase its output level above that for no-modulation case, result is output waveform shown here. Negative-going half-cycles of audio signal are modulated nicely, but positive-going half-cycles are missing. This problem shows up as "downward modulation" or decrease in antenna current when modulation is applied. It causes severe distortion, but often such signals show no apparent distortion when received because action of receivers restores missing half-cycles.

But to produce the desired results, the modulated stage must produce double the normal output voltage on the positive-going peaks. The supply power is effectively doubled at this time, because the audio power from the modulator is aiding rather than bucking the dc from the power supply. If the operating point of the modulated stage is held constant, though, the doubled supply voltage cannot result in doubled output voltage—because the efficiency of the amplifier will vary with the change in supply voltage.

To avoid this problem, most modulated amplifiers are made to be self-adjusting by use of grid-leak bias. As the voltage supplied the tube goes up, the bias will shift slightly,

THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.

144-146 MHz in. 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of hundreds of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced? Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait? Then send us a postal money order for $34.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.

CAMP ALBERT BUTLER INVITES
HAM RADIO ENHUSIASTS OF ALL AGES
TO TRY FOR YOUR
GENERAL CLASS TICKET

THIS SUMMER! OUR 11TH SEASON

STUDY INSTRUCTION LEADING to GENERAL ADVANCE and AMATEUR EXTRA LICENSE

This co-ed Amateur Radio Camp, Y.M.C.A. owned and operated, can accommodate 60 campers. There is no age limit. We have had campers from 7 through 74 years of age. It is very helpful if you can copy 5 wpm or have a Novice or Technician ticket, but it is not necessary. Time is divided between radio classes in code and theory and the usual camp activities, such as swimming, archery, riflery, hiking, etc. Golf privileges are included at the beautiful New River Country Club course.
Entire staff consists of licensed hams who are instructors in electrical engineering in some of our finest colleges and universities. Camp opens August 1 and closes August 15th. Tuition of $200 includes all camp expenses: room, meals, notebooks, textbooks, and insurance. Send for our brochure.

C. L. Peters, K4DNJ
General Secretary
Gilvin Roth Y.M.C.A., Elkin, North Carolina

Please send me the Booklet and Application Blank for the Camp Albert Butler Radio Session.

and the amplifier's efficiency will remain approximately constant. The result will be the desired doubled output voltage.

The zero-to-double swing we've been talking about is, of course, in terms of peak-to-peak values. A properly modulated rf amplifier looks to the modulator like a resistive load, so when the voltage goes up the current goes up in the same ratio. Doubled voltage and doubled current would indicate four times the power—which is absolutely right, except that the four-time figure is for instantaneous peak input power. Since rms values are only 0.707 times as great as peak values, and 0.3535 times as great as peak-to-peak values, the rms power of the modulated signal is only 1.5 times as large as that of the unmodulated carrier.

Now what are some of the common problems with high-level AM? One of the most frequent is that known as "downward modulation," in which the antenna current or output power decreases rather than increasing with application of modulation. "Carrier shift" is another. Simultaneous AM and FM is a rather common complaint at vhf and uhf, and is not unknown at lower frequencies. And "mushy" or distorted modulation seems, at times, to be the rule rather than the exception—but it's a problem too. Let's look for the causes of each of these.

The basic cause for downward modulation is simple enough. Something in the modulated stage is not right, so that when the modulator changes the supply voltage the amplifier does not respond by increasing its output. In many cases, a scope examination of the output signal reveals that it is modulated only by the negative-going half-cycles of the audio, and that the positive-going portions of the audio signal are having no effect. Since we are getting the less-than-carrier-level parts of the modulation okay, but are failing to get the greater-than-carrier-level parts to make up for them, the net result is a decrease in output power.

Strangely enough, such a signal may be perfectly readable, and often has only slight distortion. Regardless, this is still a problem, and should be cured.

The cause can be anything which prevents the modulated stage's output from going up. It may be insufficient grid drive, so that there's just nothing left from which to supply more output. It may be a poorly chosen operating point (more likely too much grid bias rather than not enough, or too little screen voltage) for the modulated stage, so that the tube is simply saturated before it can reach the double-output condition. And it may be improper adjustment of the tuning and loading controls, so that the tube is not working into a proper impedance to permit it to develop the increased output power. In this case, the problem is more likely to be under-loading under carrier conditions, rather than being loaded too heavily.

Carrier shift is deliberately introduced into TV signals to indicate brightness information, but for normal audio and high-level AM it's a problem. The effect is that of having a dc component in the modulating signal. That is, the carrier level when modulation is present is higher than when modulation is absent. The normal cause of carrier shift is simply overmodulation, which does introduce a dc component by rectification of the excess modulator power. A less common reason for this problem would be poor design of the modulated stage, so that the changes in operating point which accompany modulation would drastically change the stage's performance.

Carrier shift is introduced into "controlled carrier" systems, and is in fact the carrier control which gives such systems their name. The normal manner of introducing the shift is to control screen voltage on the modulated stage with a signal obtained from the rectified *envelope* of the modulating signal rather than with the modulating signal itself. When the modulating signal is weak or absent, screen voltage becomes low, reducing carrier level. This action reduces the dissipation in the modulated stage during no-modulation periods, and permits smaller tubes to be used than would otherwise be the case. It is seldom used with high-level modulation; the most common use of controlled-carrier techniques is with screen modulation, where the power level is limited primarily by tube dissipation and anything which reduces dissipation permits higher output power from the same tubes.

Simultaneous AM and FM is a problem in any type of system, because it's prohibited by FCC regulations. While a delicate adjustment of modulation percentages can produce single sideband (with carrier) from simultaneous AM and FM, in all other cases the presence of both types of modulation at the same time simply results in excessive use of spectrum space and often results in signals which cannot be copied on any kind of receiver.

Since frequency is controlled exclusively by the oscillator, while amplitude is controlled only by the final stage or stages in high-level AM, the only possible cause of FM and AM at the same time is for the modulating signal to be getting back to the oscillator to change its frequency. This can happen if the oscillator's supply voltages are taken from a power supply which also supplies the final, the modulator, or any part of the speech amplifier, and are not sufficiently well regulated, and this is in fact the most frequent cause of this problem.

Running a close second for the title of most-frequent-cause is inadequate isolation between the oscillator and the modulated stage, so that the varying load imposed by the modulated stage under modulation reflects back into the oscillator circuit and changes its frequency. The problem has been traced to this cause in vhf transmitters through as many as five isolating stages; it usually won't occur with that much isolation between oscillator and modulated stage, but it can.

A final cause for simultaneous AM and FM might be rf feedback from the transmitter output to the oscillator. This would be indistinguishable, in practice, from reflected loading, but would succumb to different cures (which we'll examine a little later).

Mushy modulation, or distortion, is a problem which can have many causes. Overmodulation is a frequent cause. Probably the most common reason for modulation distortion, though, is what is known as "nonlinear modulation." It's essentially the same problem we already met in connection with downward modulation, but in a less severe form. The modulated stage is unable to supply the double-voltage output level, but does supply some power increase. When it gets as far as it can, it gives up. This flattens out the positive peaks of the modulated signal, which introduces severe distortion.

Non-linear modulation has many causes. One of the easiest to understand, if not to do something about, is brought about by the use of fixed bias on the modulated stage. If the bias is held constant, and enough drive is supplied to permit full upward modulation, then grid current will be excessive. The reason for this is that a large driving voltage is required to produce full upward modulation, but at the lower supply voltages present when the modulating signal falls to carrier level or even below (the modulation "trough"), this large driving voltage produces a large flow of grid current. At the peaks, when the high voltage is needed, much of it goes on through the stage and less grid current flows.

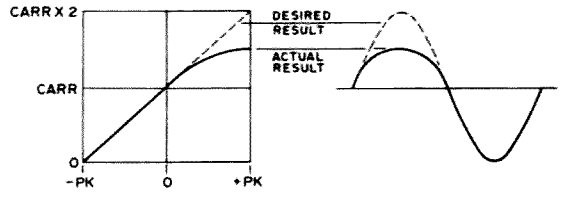

Fig. 8. If output power of modulated stage is able to increase some during positive half-cycles, but not as much as it should, the result is "non-linear modulation" as shown here. Dotted lines show the desired operation, while solid lines show what happens if modulated stage output power is limited to a maximum of 2 times carrier level rather than the necessary 4-time increase. Waveform of modulation signal is significantly distorted. This problem may be cured by increasing drive or loading, but sometimes requires redesign of the modulated stage.

Unfortunately, the grid current under these conditions is so great that tube damage can easily occur. If, then, the drive is reduced to obtain a grid-current reading within reasonable limits, there's not enough drive to supply the peaks.

It's for this reason that most high-level modulated stages are designed to use a small value of fixed or "protective" bias, and obtain most of their operating bias voltage from grid-leak bias. Together with this, the driver stage is deliberately designed to have very poor output-voltage regulation. That is, its output voltage is designed to drop off whenever much current is drawn.

Under these conditions, at modulation peaks the driver supplies full voltage because the modulated stage draws very little current from it. As the modulation cycle moves on to carrier level, the driver is required to supply more current. It can do so only by pulling down its voltage output. The grid-leak bias increases bias on the modulated stage as grid current increases, requiring a higher voltage. The result is that the driver is always struggling to supply the required drive power, and just barely succeeding in doing so. Average grid current, as indicated on a meter, remains moderate, but actual drive levels are great enough to provide linear modulation.

If, however, the driver is adjusted to supply too little drive power, full upward modulation still cannot occur. Similarly, if the modulated stage output circuits are improperly adjusted, the full upward modulation power levels cannot be achieved in the antenna.

Improper design of the modulator itself can also be a source of distortion. Unless the modulator can supply the required output power levels distortion-free, it's a waste of time trying to trouble-shoot the total system. Possible causes of distortion in the modulator include an improper impedance ratio for the modulation transformer, improper grid bias on the modulator itself, or improper performance of the audio driver stages ahead of the modulator.

Locating the source of distortion in a radiotelephone transmitter is a job which virtually requires a scope. First, the modulator must be checked out to assure that it is capable of delivering the power. Then the modulated stage must be checked, and finally the complete system.

Lacking a scope, however, it is still possible to determine the modulation capability of the transmitter. To do so, we start by assuming that the modulator can deliver at least a small part of its audio essentially distortion-free, and apply a very low percentage of modulation to the carrier. We then use our receiver as a spectrum analyzer, looking for side frequencies at twice, three times, four times, and other higher harmonics, the frequency of the modulating tone removed from the carrier. If all is working properly, these side frequencies should be absent.

Next, we crank up the audio gain of the modulator until large amounts of distortion are present, as indicated by downward modulation of the antenna current or flicker of the final-stage milliammeter, and again look for the second-harmonic side frequency. This time, it should be easily detectible.

Finally, leaving the receiver set on the side frequency, we reduce the percentage of modulation until the side-frequency signal disappears. We then search for other harmonics; if the transmitter is working properly, all other side-frequency harmonics should be absent when the second-harmonic side frequency disappears. All we need do now is to determine the percentage of modulation being applied, and that's the maximum modulation capability of this transmitter.

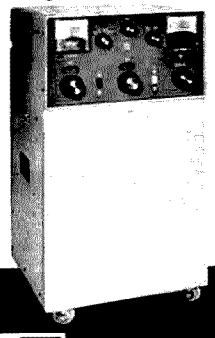
If other side frequencies are present, distortion within the modulator audio stages is indicated. Non-linear modulation normally causes second-harmonic distortion to appear in the envelope before any higher-order distortion products show up, while intermodulation in the audio stages more often results in third- or fifth-order distortion products.

To measure the modulation percentage, when the modulating signal is a sine wave, we can use a peak-to-peak indicating ac voltmeter connected across the modulation transformer secondard (DANGER—high voltage, be sure all power is off before connecting the meter!) and compare the peak-to-peak ac reading thus obtained with the dc voltage applied to the modulated stage. For 100 percent modulation, the p-p ac reading should be exactly double the dc value. For 50 percent modulation, the two readings will be equal. To get the percentage for any two readings, multiply the p-p ac reading by 50 and divide the result by the dc reading; the result will be the modulation percentage, directly.

How Can Modulation Troubles Be Cured? We've met a number of modulation problems and their causes, now. The logical final question for this installment is how to cure them.

In almost all cases, a cure can be effected simply by removing the cause of the trouble. This may, however, in the case of some forms of distortion, amount to a complete redesign and rebuilding of the modulator. Let's concentrate on some of the simpler troubles for a start, and leave redesign of the equipment until some other time.

To cure the troubles evidenced by downward modulation of antenna current, or by downward fluctuation of the final plate current meter, try first increasing drive to the modulated stage (unless it is already running with maximum rated drive). Increasing the grid bias on the modulated stage may help also, especially if drive is already at maximum. Next, check the coupling of modulated stage to antenna or other load. Increase loading as necessary to remove the trouble. Ideally, a modulated stage should be loaded to the point that the plate-current dip is barely perceptible—unless this overloads the tubes, in which case bias should be increased and screen voltage decreased as necessary to keep plate current within reasonable limits while maintaining the loading heavy.



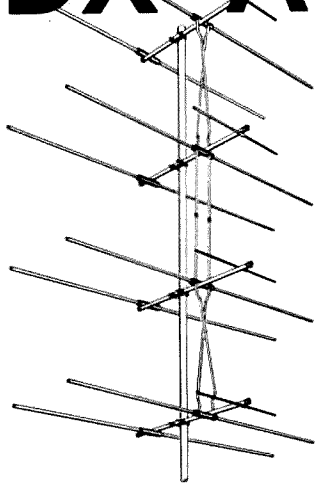
Be certain that the dc plate voltage to the modulated stage does not exceed ratings for the tubes involved; if it does, reduce it to the rated limit and see if the trouble persists. Also, check the final tubes for weak cathodes, which can cause this problem.

Insufficient modulation of the screen-grid along with the plate can cause this trouble; increasing the percentage of modulation to the screen is the normal cure. If screen voltage is taken from the plate supply via a dropping resistor, this cure normally is not applicable.

Finally, the output filter capacitors in the power supplies feeding either the modulated stage, the modulator itself, or both, may be too small, resulting in poor voltage regulation and a consequent inability to supply the necessary power peaks. Increasing the value of these capacitors is always a good idea; they can hardly be too large. If electrolytic capacitors are used (relatively common in the 100-watt class of rigs), they may have aged so that actual value is much less than the marked value. Such capacitors should be replaced.

LINEAR AMPLIFIERS
$6.60 PER POUND
SOUND RIDICULOUS?

Not at all! That is about what you will pay whether you buy a box of parts or a fully assembled, rugged, heavy duty BTI LK-2000. Extra weight means extra dependability, plus: Adequate back-up power • Good harmonic suppression • Operating convenience • Eimac 3-1000Z • ALC • Fast acting overload protection • 80 through 10 meters • Prestige styling • Adequate cooling, even on a continuous use basis.



BTI LK-2000 . . . For maximum legal amateur input . . . SSB, CW, RTTY. Price $795.00

BTI LK-2000HD . . . For heavy duty applications such as MARS, high power RTTY and SSB. Price $895.00

Write for free brochure or send $1.00 for technical instruction manual.

DUAL GATE MOSFET
PRE-AMPS

to 175 MHz. **$21.95** ppd.
to 300 MHz. **$25.95** ppd.

NEW FOR 1970!
The above models now have rf gain control.
For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

VANGUARD LABS
Dept. H
196-23 Jamaica Ave., Hollis, NY 11423

The preceding suggested cures apply to plate-modulated AM transmitters. In addition to most of the above, the following are also applicable to any type of grid-modulated AM rig:

Too much rf drive can cause downward modulation, just as can too little. With grid modulation, the drive level is critical and must be adjusted carefully to obtain optimum results.

Too light loading; this is much more critical with grid modulation than with plate modulation. Grid-modulated transmitters should be loaded so heavily that the resonance dip is not perceptible at all. When modulation is absent, the tube will be dissipating maximum power. Application of modulation then increases efficiency of the modulated stage to produce the additional output power required.

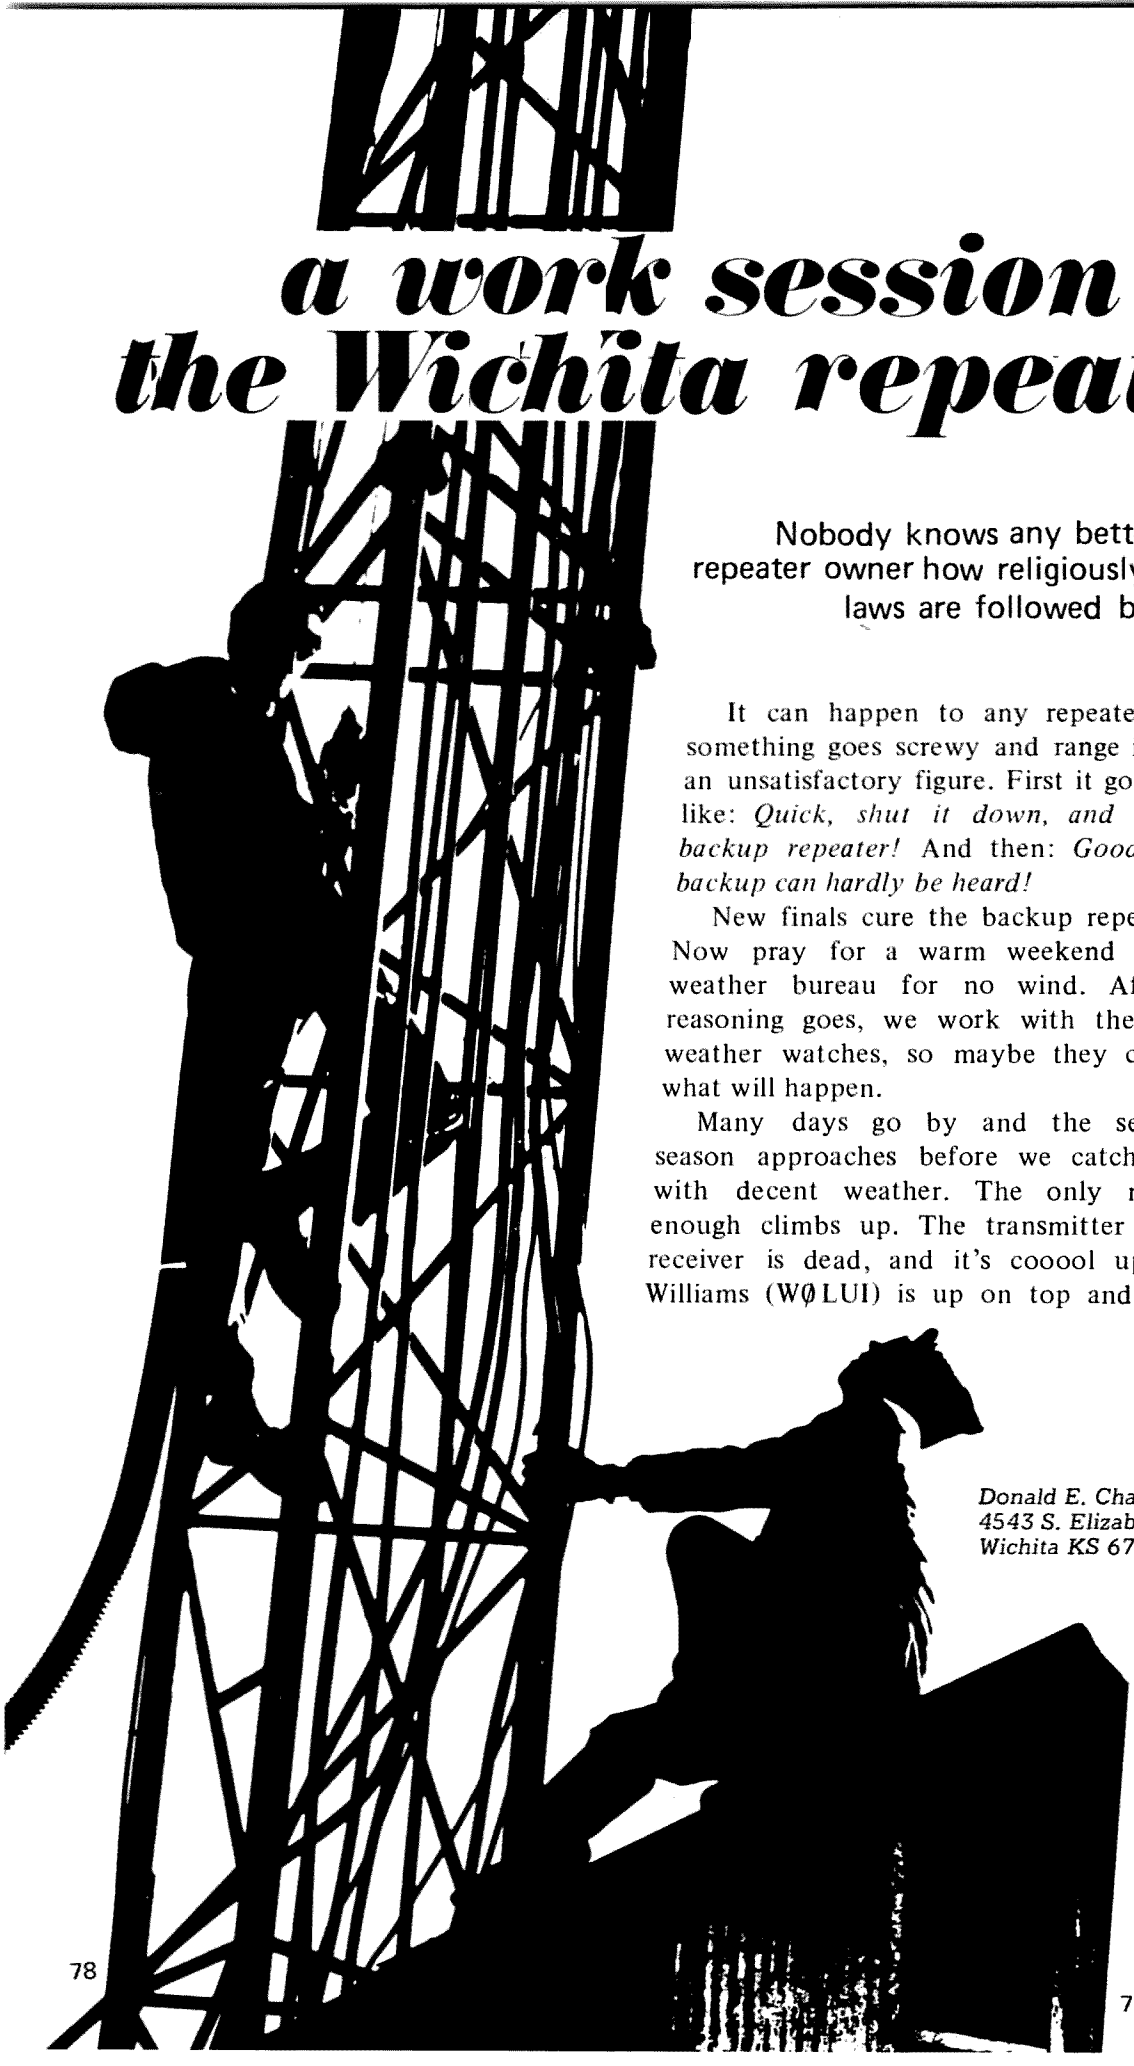
If the plate-current needle flickers upward when modulation is applied, any of several problems may be present. The problems and their cures are:

Overmodulation—cure this by turning down the audio gain or speaking more softly. This is applicable to any type of modulation.

Incompletely neutralized modulated state—cure by neutralizing the stage more completely.

Parasitics in the modulated stage—eliminate the parasitics.

When screen modulation is used, screen voltage too low—cure by increasing screen voltage.



When control-grid or suppressor modulation is employed, too much grid bias—reduce grid bias.

While all these problems and cures depend largely on the indications obtained by antenna current measurement or by observation of the final-stage plate meter, a steady plate meter or upward-modulating antenna current does not necessarily indicate good modulation. It's quite easy to get a set of conditions in which one kind of distortion on positive half-cycles of audio balances out an opposite kind on negative half-cycles, so that the current measurements look good but the modulation is really mudulation. The scope provides the only certain check on this. However, for any specific rig, the scope is necessary only once; after initial adjustment, the plate-current or antenna-current measurements can be used to spot minor departures from desired operating conditions.

Next Time. We're only halfway through our examination of transmitter operating techniques. In the next installment, we'll be looking at the problems of control of harmonics and of coupling transmitters to the antenna system, among other things.

. . . Staff

a work session on the Wichita repeater

Nobody knows any better than the repeater owner how religiously Murphy's laws are followed by Nature...

It can happen to any repeater – suddenly something goes screwy and range is reduced to an unsatisfactory figure. First it goes something like: *Quick, shut it down, and turn on the backup repeater!* And then: *Good Grief! The backup can hardly be heard!*

New finals cure the backup repeater trouble. Now pray for a warm weekend and ask the weather bureau for no wind. After all, our reasoning goes, we work with them on severe weather watches, so maybe they can influence what will happen.

Many days go by and the severe-weather season approaches before we catch a weekend with decent weather. The only man healthy enough climbs up. The transmitter is dead, the receiver is dead, and it's cooool up there. Jay Williams (WØLUI) is up on top and the 6-meter

Donald E. Chase WØDKU
4543 S. Elizabeth
Wichita KS 67217

repeater is okay, but – Wow! The 2-meter machine needs much fixing before it can go back on the air.

New tubes are sent up via the hoisting cable, but before long the bad news is discovered: A 6-inch piece of wire works better than the receiving antenna. The equipment is in working condition, but an antenna replacement is necessary.

One thousand feet of eighth-inch aircraft cable is permanently mounted to the tower. This picture shows Don Patterson (KØKN), left, and Glen Brasch (WØHYR) as they start a load up to the top. The building on the right houses the 10 kW output of KEYN-FM and microwave remote control equipment. The building on the left houses two low-band and two high-band quarter-kilowatts, two low-band and remote control stations, and two 450 MHz mobile relay stations. Also inside is the Wichita repeater identification equipment and terminal equipment for the telephone

We can't replace it today, but this is the second time in three and a half years of repeater operation we have lost an antenna. A pair of decisions are made. First, the replacement antenna will be side-mounted some 6 feet *below* the top of the tower. Let someone else be the lightning rod. Second, if possible, obtain enough low-loss feed line to bring the equipment down to the ground.

A few days go by. On friday, the weather bureau advises that Saturday will be calm, warm, an ideal day for tower work. Grab a side mount kit and a replacement antenna, and check who is available. Pushover Chase is the fall guy, as the other tower workers have to work Saturday. Don Pryor (WAØIPB) and Vic Thomas (WAØYBM) are available for ground work.

There is no substitute for having the needed part in case of trouble. This is a complete operating SPARE repeater, ready to go, in case any or all major assemblies need to be replaced. If the man on top wants any part, any portion can be hoisted up on the cable. This site, by the way, is the location of the Wichita repeater, 6400 North Hillside in Wichita. In addition to a commercial FM broadcast station, several commercial two-way radio users are on the tower along with the Wichita 2- and 6-meter amateur radio equipment. The amateurs have a 12-pair Neoprene-jacketed messenger cable running from the top to the bottom of the tower. This is used to control various functions, such as interconnecting two repeaters, carrying 600Ω audio down for monitoring, etc. When we told the local telephone once we wanted the termination for the phone line up on top, they informed us they would be happy to do it as long as they could keep one foot on solid ground. We agreed to a termination inside the building, and the local hams obtained and installed the line from ground level to the top.

All meet and have a quick cup of coffee before heading out to the tower site. It's slow work when only one man is on top but the new (well, *almost* new) antenna is checked out on the ground with vswr meters and sent up the cable.

Jay Williams (WØLUI) starting work on top of the tower. The brace he is standing on is 440 feet off of the ground. He has just opened the 2-meter repeater cabinet, getting ready to replace the final tubes. The antenna fastened to the brace he is standing on is a 450 MHz business rig. The upper left antenna (looks like it sticks out of the beacon light) is the receiving antenna for the repeater. At the lower left, the transmitting antenna is a few feet out from the tower. The antennas for the 6-meter repeater are not visible; they are side-mount types, mounted on the far leg. Several 450 MHz log periodic beams are also mounted on the far leg.

The first decision is implemented by side-mounting. The cable from the old antenna shows signs of moisture. Fifteen feet of replacement cable and all is well.

Or is it? Program material from KEYN-FM is suddenly showing up on the repeater. Careful checks of all shields, grounds, and antenna positions show that the clearance between receiving and transmitting antennas is only about 8 feet. A quick mental review of system calculations comes up with a recommended minimum separation of 20 feet. Some work with the muscles, aided by wrenches and a quantity of words (none of them the type allowed on the air) and the bottom of the transmitting antenna is now at the 380-foot level, and the receiving antenna starts at the 428-foot level.

It's getting cool, so all is given a final check, the repeater is buttoned up, and the tower jockey starts down. This takes a little while, as my muscles are tired, and I'm not quite as young as I pretend to be. But Don Pryor awaits with a cup of coffee poured and ready. As we leave the tower we enjoy the fruits of our labor. We talk to one of the hams in Mulhall, Oklahoma, one in Enid, Oklahoma, one in Hesston, Kansas, and one in Kingman, Kansas. All is truly well, the tall tower is back in service and we'll see if the weatherman is good next weekend. We now have 800 feet of foam feedline.

Now if the weatherman will give us another good weekend . . .

Inexpensive New Semiconductors For The Ham

A whole flock of new semiconductors that should interest the ham have recently appeared. They include both discrete devices and integrated circuits; this article will discuss the discrete types other than rf power transistors.

While it's obvious that no manufacturer of semiconductors makes any devices designed just for the amateur, transistors and other parts made for other uses are often perfect for his projects. High performance combined with low prices provide the proper combination for the builder.

All of the products described here have been introduced recently. All are manufactured by Motorola, the world's largest producer, and as such, are readily available from the wide network of Motorola distributors including Allied and Newark. The approximate single-quantity prices are listed. For more information on any device, consult the Motorola Semiconductor Data Book or write for a copy of the individual data sheet: Technical Information Center, Motorola Semiconductor Products Inc., Box 20924, Phoenix AZ 85036.

The schematics are taken from the Motorola Application Note listed. They are available from the same source.

Dual-Gate MOSFETs TO-72

A real boon to the rf designer is the dual-gate MOSFET, unmatched for low

noise, high gain, low cross modulation, and resistance to overloading in VHF and HF amplifiers. The MFE3006 ($1.50) features 25 dB typical gain at 100 MHz; it's also ideal for lower frequencies. The MFE3007 ($1.62) features 21 dB gain, 3 dB noise figure at 200 MHz. The MFE3008 ($1.29) is similar, but specified for mixer use. All have exceedingly low feedback capacitance (0.02 pF typical), so don't have to be neutralized in normal applications. Incidentally, these MOSFETs, like all made by Motorola, feature silicon nitride passivation and are not superdelicate like most other MOSFETs.

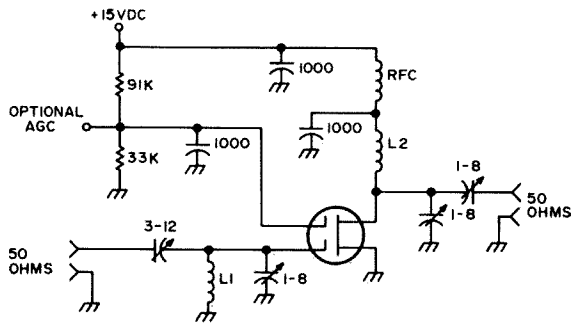

Fig. 1. Typical VHF amplifiers using MFE3007 dual-gate MOSFET. Taken from Motorola Application Note AN-478.

Typical 100 and 200 MHz amplifiers are shown in **Fig. 1** (TO-72 case).

Cheapies but Goodies

A new approach to inexpensive transistors is found in the NPN MPSA10 (29¢), NPN MPSA20 (33¢), and PNP MPSA70 (38¢). Instead of being falloffs from more expensive types, these new transistors are prime devices designed to be inexpensive. They use small dice, simple processes, and are specified to have optimum yield. All of these contribute to the low cost.

The three transistors are ideal for all general audio and low rf applications. They have BV_{CEO} of 40V, h_{FE} of 40 to 400, C_{ob} of 4 pF maximum and minimum f_T of 50 MHz (MPSA10) or 125 MHz (MPSA20, MPSA70). The data sheets are very complete for such inexpensive parts (TO-92 case).

For even lower prices, the transistors are offered in kits containing three, five, or nine transistors of a type with various h_{FE} selections. For instance, the MPSK12 costs $2.07 and contains nine MPSA10s: the cost per device is only 23¢.

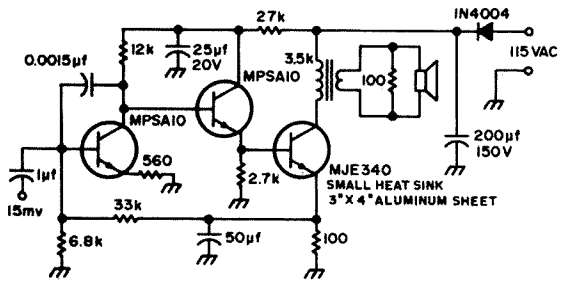

Fig. 2. 2½W line-operated amplifier. Motorola Application Note AN-426A.

A typical application is shown in **Fig. 2**, a line-operated 2.5W amplifier using a "solid-state 50L6," the 300V MJE340 silicon power transistor ($1.06).

Darlington Amplifiers

New plastic Darlington-connected amplifying transistors offer exceptionally high gains in single packages at low prices: MPSA66 (PNP, at 63¢, 75000 minimum h_{FE}), MPSA12 (NPN, 67¢, 20000 h_{FE}), MPSA13 (NPN, 47¢, 5000 h_{FE}) in TO-92 case. A 2W amplifier using an MPSA12 as a preamplifier is shown in **Fig. 3**.

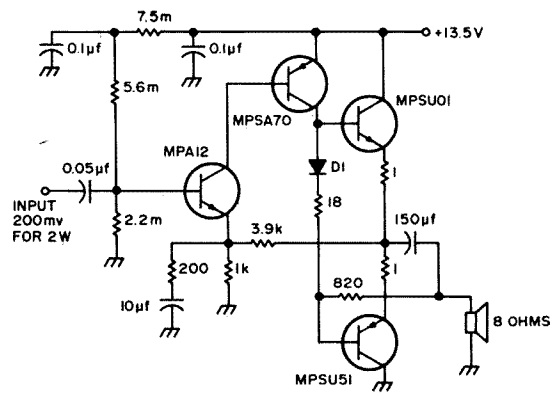

Fig. 3. 2W Audio amplifier. Motorola Application Note AN-426A.

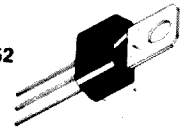
UHF Oscillator

A new plastic transistor, the MPSH10, is designed for use as a UHF and VHF oscillator in TV sets. It's also excellent for ham use as a free-running or crystal oscillator. The MPSH11 has high f_T (650 MHz minimum), complete Y-parameter specs, and costs only 49¢ (TO-92 case).

Uniwatt Transistors

A new case for intermediate-power transistors is the Uniwatt plastic package (case



152). It is similar in construction to small-signal plastic transistors, but is larger and the metal tab on which the transistor chip is mounted is extended out of the plastic. The tab can be mounted on a heatsink for dissipation of up to 8W (the value depends on the specific transistor). The Uniwatt package was developed for use in consumer equipment such as complementary audio amplifiers and video drivers, so the transistors using it are inexpensive.

A useful complementary pair of Uniwatts are the NPN MPSU01 ($1.15) and PNP MPSU51 ($1.33), suitable for audio amplifiers with up to 5W of output.

A useful general-purpose Uniwatt is the NPN MPSU02 (99¢), similar in characteristics to the popular metal-cased 2N2219. It has a BV_{CEO} of 40V, h_{FE} of 50, typical C_{ob} of 2 pF, and a minimum f_T of 150 MHz (typically 400 MHz). Though it's designed for general-purpose use such as audio, it has been found useful for many rf applications as well.

Information on mounting and heatsinking Uniwatts is found in Motorola's application note AN-472.

High-Voltage Drivers and Amplifiers 152

Three new high-voltage transistors are excellent for use as Nixie or neon-tube drivers, scope tube drivers, or general-purpose high-voltage applications. The NPN MPSL01 (59¢, 120V BV_{CEO}) and PNP MPSL51 (61¢, 100V BV_{CEO}) are small, TO-92 case transistors with gains over 40, f_T over 60 MHz, and C_{ob} of 8 pF maximum. They have very complete data sheets.

The MPSU10 is a Uniwatt transistor (case 152) with a 300V breakdown rating, dissipation of up to 5W, h_{FE} of 40 minimum at 10 mA, f_T of 60 MHz minimum, and a C_{cb} of 3 pF maximum. And it costs only $1.50.

Power Transistors

The most popular silicon power transistor is the NPN 2N3055, a metal-cased device that costs about $2.05. A new plastic version, MJE3055, has similar specifications, yet cost only $1.41. And a PNP complement is also available (MJE2955, $2.90). Both have V_{CEO} of 60V, h_{FE} of 20 to 70 at 4A, power dissipation of 90W and f_T of 2 MHz minimum (case 90). The MJE3055 is ideal for general amplifying and switching use.

The Cheapest Transistors TO-92

The bottom of the price list is occupied by the 2N5223 at 21¢. While it does not feature great specs, it is satisfactory for many general-purpose applications: BV_{CEO} = 20V, P_D = 310 mW, h_{FE} = 50 to 800 and f_T = 150 MHz minimum (TO-92 case). The MPS5172 has the same price.

Voltage-Variable Capacitance Diodes 182

Voltage-variable capacitance diodes (varactors) are very useful in FM modulators, test equipment, afc, low-level frequency multipliers and RTTY frequency shift. Four new varactors cost only 53¢ apiece: MV2201 (6.8 pF), MV2203 (10 pF), MV2205 (15 pF) and MV2207 (33 pF). They have Q up to 300 and tuning ratios of about 2 at voltages of 1 and 10. Similar varactors with better even specs and capacitances up to 100 pF (MV2101 through MV2115) cost only 90¢ (case 182).

Thyristors 90

Four new silicon controlled rectifiers—MCR407-1 (30V, 82¢), MCR407-2 (60V, 97¢), MCR407-3 (100V, $1.05) and MCR407-4 (200V, $1.20)—are 4A thyristors with small turn-on requirements (case 90).

High Voltage Rectifiers

59

High-voltage silicon rectifiers have been relatively expensive in the past, making it necessary to use many devices in series in most practical applications. A new family of rectifiers offers PIV up to 5000V at relatively low prices. Examples are the MR990A rated a 1 kV and costing only 35¢; and the MR996A, 5 kV and $1.35. All are rated at 250 mA forward current and are in small plastic packages (case 59).

RENOVATING SURPLUS METERS

A test or two, and maybe just a dab of opaque white paint . . . and presto!

Even today, many years after World War II and the Korean conflict, the surplus market is flooded with meters of all shapes, sizes, and ranges. Many are calibrated in *pps*, *QXR/2*, or *squitter*. This terminology means something to someone but doesn't mean much to you when you want to read plate current. Some surplus dealers have been kind enough to include the actual scale in their advertising, while others let you take a chance of getting something truly useful for your money.

In either case, several steps are necessary to convert the scale to understandable terminology. When your bargain arrives, arrange a test setup to determine exactly what you have. Probably the easiest way to find the full-scale calibration is a series circuit as in Fig. 1. The series resistance is adjusted to

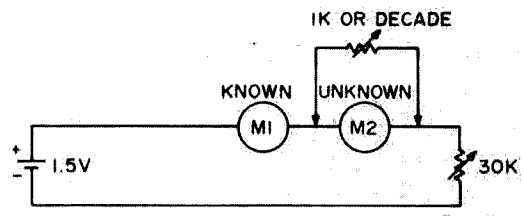

Fig. 1. Check the internal resistance of the meter by adding a variable parallel resistance across the unknown meter. Removal of the resistance gives an indication of meter sensitivity.

a full-scale indication on the tested meter and the value is read on the known meter. This is the sensitivity. A resistance decade or pot is then added in parallel with the meter and adjusted to half-scale indication. The value of the parallel resistance is equal to the internal resistance of the meter. Both the sensitivity and internal resistance should be scribed on the case for future reference. Obviously, it would be in the best interest of

both meters to start with a high series resistance and a high known meter scale.

Once you know what you have you are in a much better position to put it to use. The meter must now be disassembled; commonly, this is done by removing three screws around the rear circumference of the body or two screws on the back. The holes may have been sealed, in which case the sealing compound must first be removed. Slide the movement onto a clean, white, lint-free surface. Immediately check for the presence of an internal shunt or multiplier which may have caused false readings during the earlier tests. If a shunt is found, remove it. A multiplier should be shorted. In either case, recheck as previously described.

It is a relatively simple matter to change the scale. It may be as simple as marking out the legend with typing correction fluid. The existing scale can often be used by removing the old numbering as above and re-marking with decals or transfers either of the standard type or ones made especially for meters. For any work more elaborate than removing a legend it would be best to carefully remove the scale. This is normally accomplished by removing two small screws, one on each side of the scale and usually in line with the meter pivots. Use only a jeweler's screwdriver and exercise caution to slide the scale out without touching the needle or hairspring.

Perhaps your meter has only "good–bad" markings and no calibrations. All is not lost. After the scale has been removed, paint the scale area with a good coat of flat white paint and allow to dry thoroughly. Measure the length of the needle excursion using either the old scale or the needle itself. Cut and apply a new set of graduations from the variety included in the meter and panel marking transfer set available from dealers for *Letraset* transfers. Add whatever legend and calibrations you need and carefully reassemble. The cost of the transfers is rather high for conversion of only one meter but when several are to be done the cost per unit is quite reasonable.

A Simple Bias for Linear

Shunt regulation for bias supplies offers the advantage of low constant-current

With the exception of those circuits using zero bias tubes, class AB2 and class B operation of linear amplifiers appears to have been largely neglected by the radio amateur. The reason for this is not hard to find. The little literature which is available on the subject invariably shows bulky and elaborate regulated bias supplies, often containing five or six tubes, being used to maintain the bias voltage at a steady value while the grid current surges to 100 mA or more with each transmitted syllable. Some form of regulation is, of course, essential, for the bias voltage would otherwise swing wildly with each surge of grid current. But this regulation can be provided so simply using semiconductors that it need no longer influence the choice of amplifier type.

The regulator described in this article possesses the following features: (1) It contains only five small components, costing approximately $3, and requiring about two cubic inches of space. (2) It is a two-terminal device which is connected to the amplifier at the point where regulation is required. No separate power is needed. (3) The bias voltage may be adjusted by the turn of a knob to any value between 40 and 100 volts (other ranges are available by changing the component values). (4) It can be used for any class of amplifier, radio or audio frequency, whether grid current flows or not, but as described above, it is of particular value for class AB2 or class B amplifiers. (5) It will hold the bias voltage within 1.0V of the selected value during grid current excursions up to 100 mA, or within about 4V for a current up to 400 mA. (Closer regulation could be obtained with additional components but is not necessary.) (6) It can be used in conjunction with almost any bias supply of suitable voltage, and only a small current is taken from the supply, regardless of the value of grid current to be handled.

Bias regulation differs from the more common use of regulators in power supplies in that grid current flows backwards into the supply instead of drawing current from the supply. The shunt type of regulator is ideal for this application because it can be designed to draw only a very small constant current from the bias supply and yet accommodate a heavy flow of grid current from the linear amplifier while maintaining the bias voltage constant (see Fig. 1). The more commonly used series regulator does not possess this property, but must be set up for a power supply drain greater than the peak grid current to be catered for (see Fig. 2).

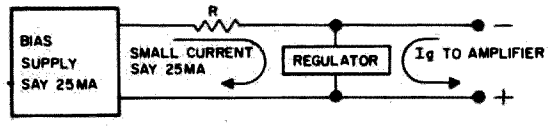

Fig. 1. Shunt regulation.

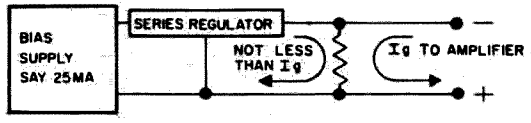

Fig. 2. Series regulation.

Regulator Amplifiers

drain, and it can be used with the neglected class B and AB2 linear amplifiers.

I have therefore based my design on the use of shunt regulation, and evolved the simplest possible circuit that will give adequate regulation plus an adjustable voltage. The practical circuit is given in Fig. 3.

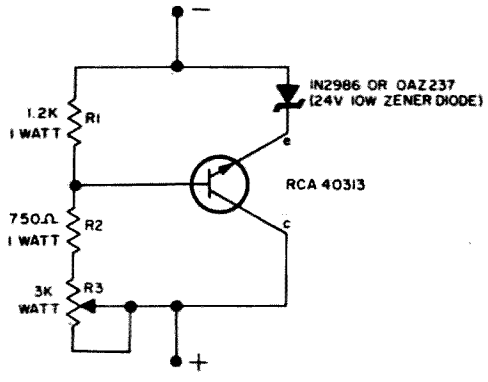

Fig. 3. Practical regulator circuit.

Resistors R1, R2, R3 form a voltage divider which applies a fraction of the total voltage to the base of the transistor, while the emitter voltage is fixed by means of the zener diode. The device regulates in such a manner that the voltage between base and the negative terminal just exceeds the zener voltage. Any further increase in voltage is then opposed by the heavy increase in transistor current which results. The voltage at which the device regulates is changed simply by altering the ratio of the base dividing resistors. The base could be connected to the moving arm of a potentiometer, with fixed resistors from either side of it to the plus and minus terminals, but if this were done, the bleeder current would increase needlessly as the regulated voltage was increased. With the circuit shown, the bleeder current (through R1, R2, R3) remains constant as R3 is varied. To allow for different bias supply units, the series resistor R (Fig. 1) should be chosen so that a current of between 15 and 20 mA flows into the regulator when it is set for maximum voltage (i. e., R3 at maximum). As the regulated voltage is reduced, the voltage drop across R will increase and cause an increase in the current through it and through the regulator. This is of little consequence unless the bias supply is rated at less than 30 mA, in which case R could be made adjustable and coupled to R3; or, alternatively, R could be replaced with a constant-current device. These refinements, however, will not generally be necessary or desirable. The bias power supply unit itself need not possess good regulation; in fact, a poorly regulated supply giving a drooping voltage-versus-current curve is desirable to minimize the current changes described above.

If it is desired to substitute other components or alter the range of the regulator, watch the following points:(1) The higher the zener voltage the better the regulation, but it must be less than the required minimum regulated voltage. (2) The transistor must have an adequate voltage rating. (The RCA 40313, with a 300V rating, is good for the highest bias voltages likely to be required.) (3) Watch the dissipation – transistor and zener both carry the full grid current. (4) Determine the maximum base current (maximum

grid current divided by beta). (5) Select the base divider resistors to pass between 10 times the base current.

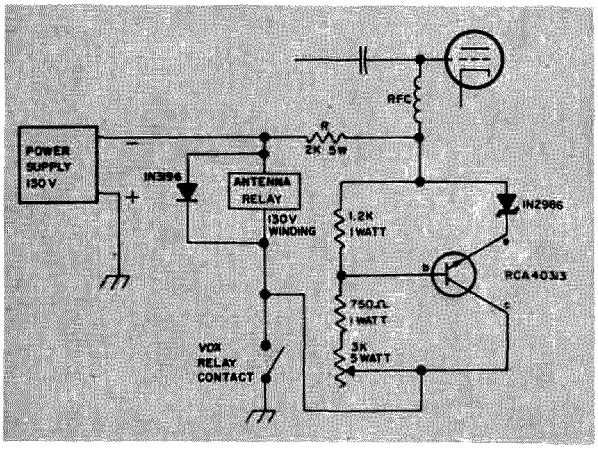

Fig. 4. Biasing the linear amplifier.

Figure 4 shows the regulator in a practical circuit for a linear radio frequency amplifier.

With the VOX relay open, maximum bias voltage is applied to the amplifier to bias it off. When the VOX relay operates, the bias falls to the value set by the regulator, and the antenna relay changes over. The diode shunting the relay coil is to avoid damage to the regulator, due to the "kickback" of the relay winding. Should the "slugging" effect of this diode cause the relay to release too slowly, the diode could be placed across the regulator unit instead. The positioning as shown has the advantage, however, of preventing sparking at the VOX relay contact due to the relay inductance.

If the antenna relay arrangement is not required, simply omit relay and diode from the circuit. If the provision for biasing back the amplifier during standby is not required, the positive end of the regulator should be earthed directly and the transistor case may in fact be bolted to the transmitter chassis without any insulating washer.

I have shown a 130V power supply, but this could be considerably higher (or lower if only a reduced voltage is required). In either case, choose the series resistor R as described earlier.

The circuit of Fig. 4 has been designed to handle a considerable amount of grid current, but the same circuit without any change whatever may be used for class AB1 or other amplifiers which do not draw grid current.

DESIGN FOR A HIGH PERFORMANCE I-F AMPLIFIER AND AGC SYSTEM

For CW or SSB work, you'll find this system hard to beat with its fast-attack/slow-decay characteristics. A wide latitude of stage gain is assured with both forward- and reverse-acting agc circuit elements.

This paper describes the design and operating conditions of an i-f amplifier which is intended to be part of a complete SSB/CW receiver or transceiver project. It uses modern components and techniques and has extremely good agc characteristics.

The circuit also offers high gain and is ideally suited for both CW and SSB applications, since a fast-attack and slow-decay agc characteristic is available. Although this particular amplifier was designed and tested for use at 9 MHz, the design is equally suitable for any i-f between 50 kHz and 10.7 MHz.

Transistors and AGC Circuits

When transistors were first introduced into rf and i-f circuitry it was generally observed by amateurs that although high stage gains could be readily achieved the circuits did not offer a very good agc performance. Most of the circuits employed simple forward- or reverse-acting agc circuits, offering limited range of gain control.

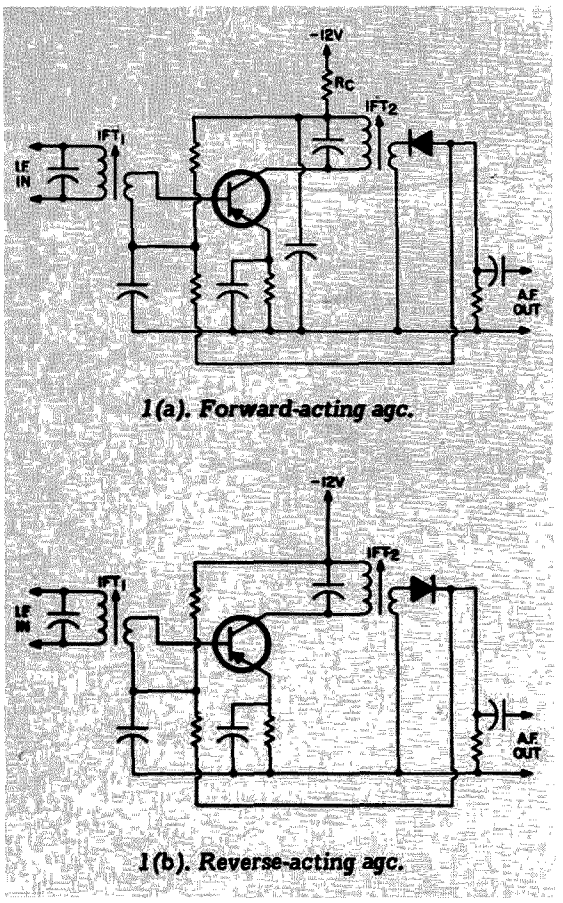

Fig. 1. Simple agc circuits.

Figures 1a and 1b show simple forward and reverse agc circuits. It will be seen that in the reverse-acting agc circuit, the detected i-f signal is fed back as a dc control voltage to bias the transistor amplifier off, reducing the collector current and hence the stage gain. In the forward-acting agc circuit, the dc control voltage biases the transistor on, increasing the collector current. However, due to the presence of a resistance in the collector circuit the collector voltage is decreased, resulting in a reduced stage gain.

The prime disadvantages of such a system, particularly when CW or SSB reception is required, are–

- Limited range of stage gain control
- Excessive agc attack time
- Bfo voltage introduces unwanted agc voltage.
- Detector linearity reduced by agc loading, introducing unwanted audio distortion.

To overcome these difficulties, the circuit described below was developed. It employs both forward- and reverse-acting agc circuitry to obtain a wide range of stage gain control.

Design Considerations

To insure adequate sensitivity in a receiver using an rf amplifier stage, it is generally necessary to have at least 50 dB of gain available in the i-f amplifier. The figure may be estimated by considering the overall receiver gain required from the antenna input to the demodulator stage for a 1 μV input signal.

Assuming a 10 mV signal is required at the product detector, the overall gain required is

$$dB = 20 \log \frac{10 \times 10^{-3}}{10^{-6}}$$

$$= 80 \text{ dB}$$

This gain is shared between the receiver front end and i-f stages and it is reasonable to expect about 30 dB gain from the former, leaving 50 dB to be made up in the latter. It should be noted that these figures include transformer and filter losses in the circuit. Thus, with a 1 μV input signal the i-f amplifier receives an input signal of about–

$$\mu V = \text{antilog} \frac{dB}{20}$$

$$= \text{antilog} \frac{30}{20}$$

$$= 32 \mu V$$

The ability of a receiver to hold its audio output level constant under conditions of signal fading is determined by the agc characteristics. Figure 2 shows the ideal receiver agc characteristics in which the

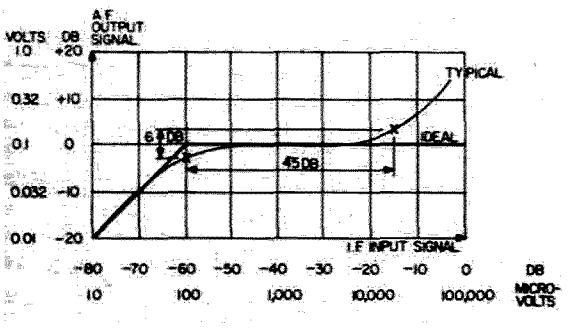

Fig. 2. Ideal and typical agc characteristics. The typical curve shown is that measured for the circuit described in the text.

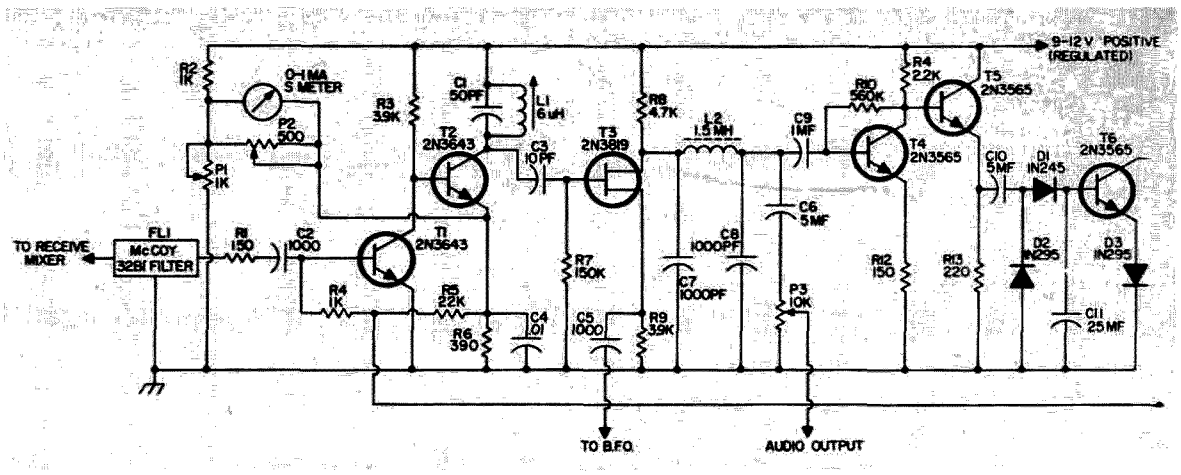

Fig. 3. Circuit diagram of the i-f amplifier, product detector and agc system.

audio output level should increase linearly with increasing signal input from zero up to some threshold level, whereafter the agc becomes effective and holds the audio output level constant even though the input signal level increases. Such a characteristic, particularly if the threshold level is correctly chosen, makes for comfortable operation of the receiver and reduces listening fatigue.

The threshold voltage level is generally chosen to be just above the level of voltage which appears at the detector input due to amplified band noise. Thus, with a front end gain of 30 dB, and assuming a band noise level equivalent to an input of, say, 1.5 μV, the i-f amplifier should have a threshold set to permit agc action on signal levels of greater than, say, 2.5 μV. This represents an input signal of 80 μV into the i-f amplifier, or 25 mV into the product detector before the agc system becomes effective.

I-f Amplifier and Product Detector

The complete i-f amplifier circuit with associated product detector and agc system is shown in Fig. 3. The i-f amplifier consists of dc-coupled transistors T1 and T2, the former of which is an untuned amplifier while the latter employs a tuned collector load. Direct-coupled negative feedback is applied over both stages from the emitter of T2 to the base of T1, insuring stable operation of the amplifier. The overall selectivity of the i-f amplifier is solely determined by the preceding filter unit (FL1). The output is capacitively coupled to the gate of the FET product detector whose high input impedance offers a negligible loading on the collector tuned circuit of T2. A bfo injection voltage of about 2V peak is fed to the drain of the product detector. This stage will handle input voltages up to 1V peak-to-peak before any distortion becomes evident. Since the agc system is effective in reducing any received signal to a level of less than 1V at the product detector input, no i-f gain control is required. The audio output is filtered by C7, C8, and L2 before being applied to the audio volume control and the agc amplifier.

The AGC System

The audio signal from the product detector is amplified by T4 and transformed to a low-impedance source by emitter follower T5. This enables capacitors C10 and C11 in the voltage doubling agc rectifier circuit to charge quickly to speech syllables, giving a fast agc attack time. The rectified audio appears as a positive voltage which is applied to the base of dc amplifier T6 causing it to conduct. Conduction in T6 reduces the base bias applied to i-f amplifier transistor T1 introducing, in effect, reverse-acting agc action.

Due to the direct coupling between T1 and T2, as T1 is reverse biased by the agc action, the collector current decreases, permitting the collector voltage to rise and thus

forward bias T2 introducing, in effect, forward-acting agc action in the second stage.

The rectified agc voltage decays across capacitor C11, which determines the agc release time.

Circuit Construction and Adjustments

The i-f amplifier/agc system is ideally suitable for assembly on a printed wiring board. Layout is not critical so no detailed construction data is required. The overall gain of the i-f amplifier may be altered by changing the value of R3, increasing the value to reduce the gain and vice versa. The agc decay time may be raised by increasing the value of capacitor C11. It is important that the complete circuit be tested or used, fed from a well decoupled power supply source. It is recommended that a regulated power supply be employed to meet this end.

Circuit Performance

When preceded by a single conversion receiver front end and a crystal filter, the complete circuit gives excellent performance on both SSB and CW signals. AM is of course tuned in the SSB mode by selecting either the upper or lower sideband. Even on the strongest signals likely to be encountered, no overload of the product detector is evident in the nature of a distorted output signal, showing the effectiveness of the agc system.

The complete circuit was subject to laboratory evaluation and the following table summarizes the measured prime specifications—

Parameter	Value
Maximum i-f gain	50 dB
I-f input signal required for agc threshold	100 μV
I-f input signal required for detector overload	250 mV
Change in i-f input signal for 6 dB change in audio output signal	45 dB
Af output signal voltage	100 mV (peak-to-peak)
Agc attack time	12 msec (calculated)
Agc decay time	1 sec

... ZL2BDB ■

Single Sideband on the All Wave Radio

A miniature tunable oscillator provides an ideal source for a beat-frequency signal, and allows you to hear code and sideband on any selective receiver without making modifications to your store-bought gear.

R.E. Baird W7CSD
3740 Summers Lane
Klamath Falls OR 97601

Currently on the market there is a large selection of AM/FM all-wave receivers ranging from solid-state portables for less than $50 to some well over $200. None of these provide for SSB reception. A neighbor of mine recently bought a $200 model for listening to AM, FM, short-wave broadcast, which he thought could be used as a ham receiver for his teenage son. After due experimentation, the gentleman commented, "I paid $200 for this set and I still can't hear what I want to hear!" He was referring to the "monkey chatter" of single sideband without the proper system of detection.

One solution to this problem is the installation of a bfo oscillating at the i-f, but this involves undesirable modification of circuitry and interconnecting wires. This led to development of a modification that solves the problem at the input with no electrical receiver connections. The circuit shown in Fig. 1 is primarily a stable vfo operating at the signal frequency of the SSB station or on a harmonic of its low-frequency fundamental.

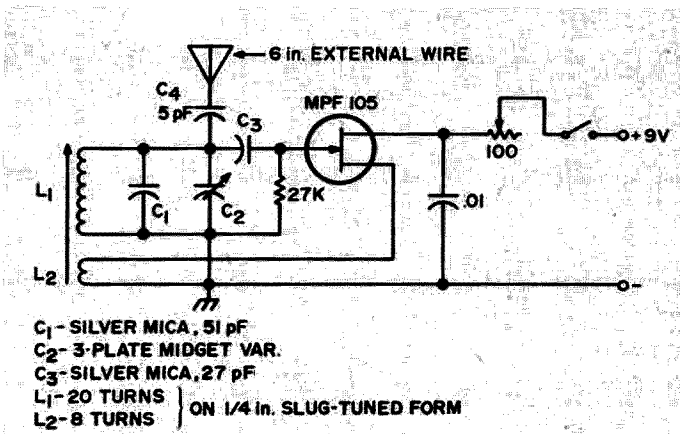

Fig. 1. The tiny oscillator circuit operates from a standard 9V battery. A small hunk of wire provides an antenna sufficient to assure healthy output for several feet. Placed close to a conventional all-wave receiver, the unit provides sufficient carrier injection for copying single sideband and CW.

Since the user was principally interested in the higher frequency amateur bands, the oscillator is designed for the 7 MHz region. It was found that the harmonic content on 14 and 21 MHz was sufficient to deliver the necessary amount of carrier injection for satisfactory reception of SSB signals. This oscillator is designed to supply the missing carrier to the SSB signal, so stability and ease of tuning were of prime concern. At the same time I naturally wished to use junkbox parts as far as possible.

Construction Features

The size of the unit is dictated by the size of the vernier dial used. In my case an old 4 in. vernier dial was resurrected from antiquity as was also the small aluminum box. With a smaller dial the box could be reduced in size materially.

When building a stable vfo, a certain amount of experimenting always seems to be necessary. Cookbook directions are not very helpful. Actually the coil used was a surplus one from which half the turns were removed, leaving L1. L2 was added on the other half of the form in the same direction. (In case the circuit fails to oscillate, reverse the L2 leads. I had to do this because I wasn't sure which way the lacquered L1 was wound.)

In any event, the combination of L1, C1, and the slug may need to be adjusted to cover 7.0 to 7.3 MHz. A silver mica for C1 gives good stability after initial warmup and permits monitoring of SSB signals for extended periods on a basically stable receiver without adjustment. If even better stability is needed, a small disc ceramic, maybe 5 pF, might be reset in parallel with C1. This would yield stabilization by causing drift in the opposite direction. Capacitor C2 is any small midget available.

Operation

After first locating the wanted signal without the bfo, zero in with the bfo. You are trying to tune to within a few hertz and, even with a good vernier dial, this is difficult at 7 MHz. You can easily get approximate tuning. Now the R2 potentiometer comes into play. It was found that drain voltage affected the frequency to some extent, so a 100-ohm pot was placed in series with the +9V and the drain. This seems to provide a very handy fine-tuning device. With this front panel knob you can tune with some precision. If perfect tuning is in the center of the range you will have a quarter of a turn either way for the intelligibility range. With a little practice you will learn how to set the main control for the proper sideband and make final adjustment with the fine tuning.

This device was tried with several all-wave radios which ranged from a 1936 Zenith (the one with the dinner-plate dial), to a cheap transistor set, to a good $200 one. In the case of the Zenith and the $200 Jap job, reception was good enough for serious amateur reception. The cheap transistor set was not too stable itself and requires a bit of signal chasing. Certainly the outboard oscillator was better than the local oscillator in the set.

In general, very satisfactory sideband reception is possible using this front end bfo. And it works equally well for 7, 14, and 21 MHz. . . . W7CSD ■

VACUUM TUBE LOAD BOX

by Jim Ashe

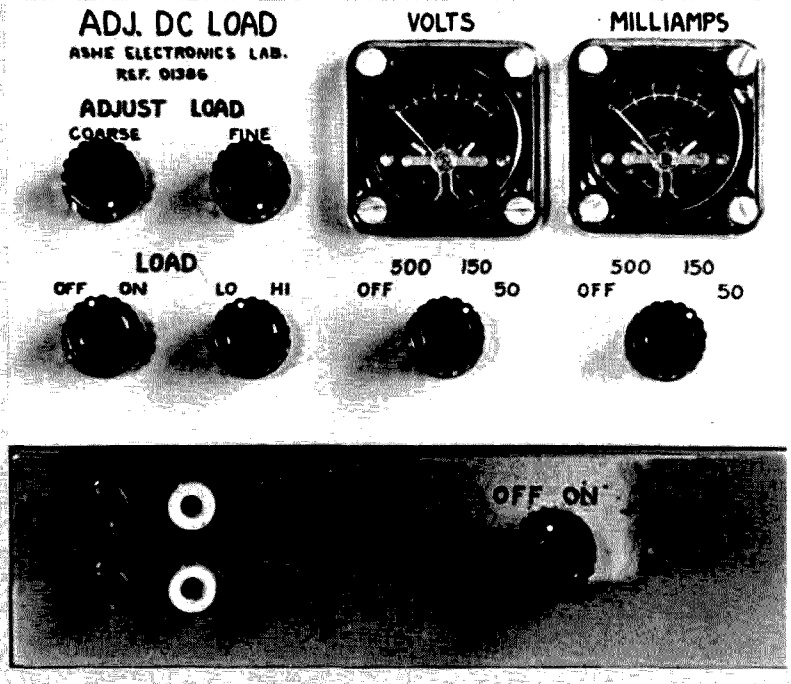

Fig. 1. Front view.

How do you test a power supply? By asking it to supply power. Put it to work, and check its output voltage for various load conditions, its hum characteristics, and its overload performance. These simple, informative tests should be easy, but usually they are not. How about something which will make them nearly as straightforward as testing resistors?

The very simple load box described here uses a pair of 6GE5's as variable resistors to dissipate the supply's power. Its minimum resistance is roughly 1000 ohms and it will load supplies at as low as 30 or 40 volts. The rated dissipation of 35 watts may be exceeded by a factor of two or three for brief tests.

A small part of the power dissipated by the load box goes to heat resistors in the load circuit. Most of it appears at the 6GE5 anodes and is thrown away as heat radiation.

The triode-connected 6GE5's are capable of passing very heavy currents but are restrained to useful loads by an adjustable negative grid bias. The grids draw no current, so large powers can be controlled by adjusting a 2-watt pot. A second pot, in series with the first, serves as vernier and for control of grid voltage at near-zero bias.

Two cathode resistors weaken the dependence of tube currents upon grid bias by adding a little self-bias. This also serves to stabilize and equalize tube loads. By switching two additional resistors across the two permanently installed ones, somewhat higher currents may be drawn for low-voltage test work.

A simple power supply provides heater voltage for the 6GE5's and a well-filtered bias potential. The thorough filtering and neon regulator guarantee that ripple ob-

served in the loaded supply's output originates in the supply rather than the load.

Ballpark accuracy is sufficient for most amateur purposes. Two inexpensive meters of unknown origin serve to indicate voltage and current. The voltmeter multiplier resistors were estimated from the roughly known meter resistance, and then chosen by bench test.

The milliammeter circuit is based upon a 10-ohm wirewound resistor. The current is measured as a small voltage appears across

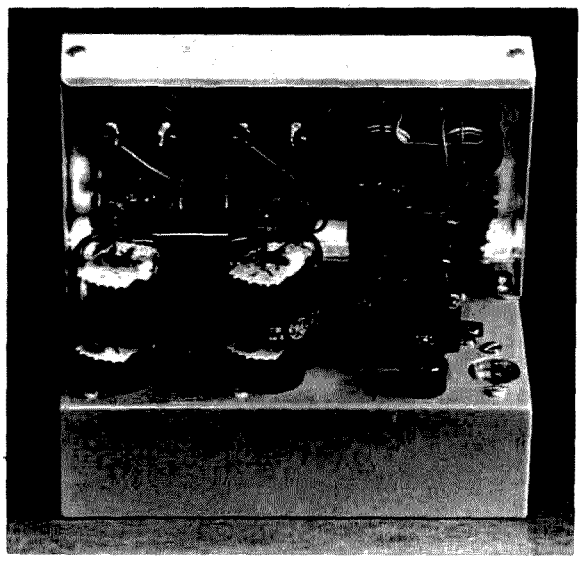

Fig. 2. Back view.

this resistor. Multipliers were chosen to read the voltage, a slight departure from usual practice. A 500 ma range, which may seem a little high, helps avoid pinning the meter when setting up for a test.

When the grid bias is near zero at high anode voltages, relaxation oscillations may occur. Their cause is not apparent. The cathode and anode resistors minimize the nuisance value of these oscillations, which occur only under extreme operating conditions.

Construction

A 5" x 7" x 2" reinforced aluminum chassis provides just enough room for construction. The 6GE5's are placed to the rear, not too close together, for best ventilation. The 4" x 7" front panel was made of .050 sheet aluminum by a local sheet metal shop. It was bent square with a ½" lip at the bottom and a 1¼" lip at the top, bent over again at the back. See Fig. 2. This arrangement makes a very convenient handle. During construction the right angles were adjusted for a rearward tilt of about 5/8". A pair of 1" strips at the sides serve as panel braces.

After completing the metalwork, all parts were cleaned in strong detergent, roughened with wet sandpaper and spray-painted with Rustoleum enamel. Hand lettering with waterproof India ink was covered by a finish coat of clear enamel. The complete process is described in the May issue of *73* Magazine.

Parts arrangement is not critical, except for one circuit. The high-impedance 6GE5 grid wiring should be kept well clear of the ac lines to avoid imposing 60 hz hum on the load box's resistance characteristic. Five lug strips bearing a total of 37 tie points were mounted under the chassis, and 23 points were used in construction.

High voltage dc is hard to turn off without a special switch. This load box used an ordinary rotary switch, and if this switch were opened to break a heavy current, it would arc. A ceramic HV switch is indicated for this application.

Using The Load Box

The load box is very useful for new work, debugging, and for servicing. When initiating

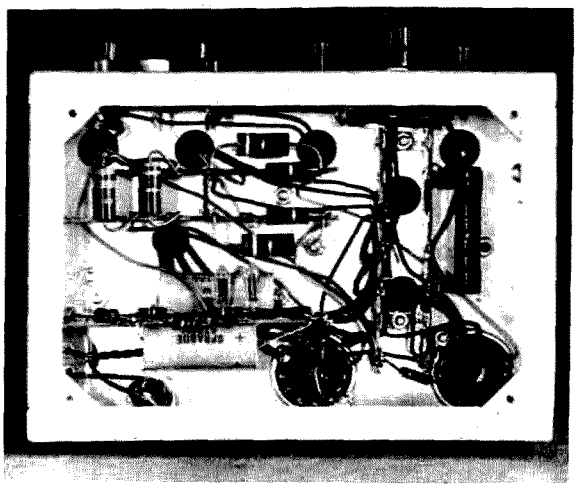

Fig. 3. Bottom view.

a new project, the power supply can be stuck together on the bench and subjected to realistic loads and overloads. When it finally goes into the chassis it can be trusted. If you missed this simple step you may still

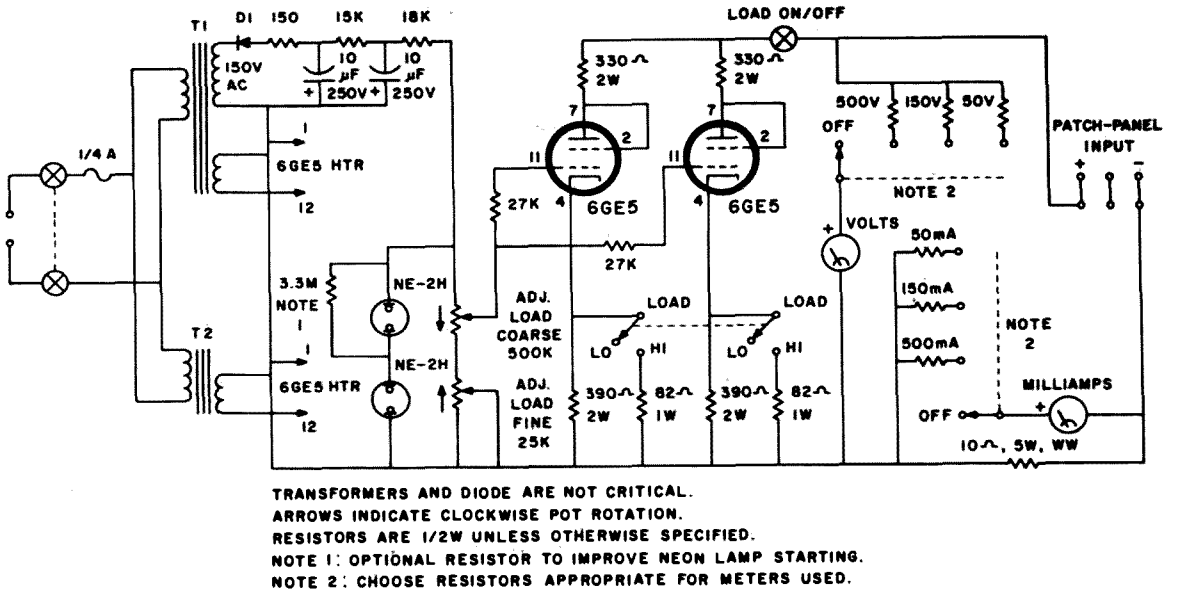

Fig. 4. Schematic.

come out ahead if you use the load box to seek out weaknesses in a supply already built. And it's good for service work too.

If necessary, disconnect the supply from its normal load while the load box is warming up. Choose meter ranges for higher voltage and current than the supply is expected to produce. Turn both adjust controls full anticlockwise, and attach the load box to the power supply.

Turn on the supply, and the voltmeter should indicate the supply's voltage. Turn on the load switch and advance the coarse load control until the milliammeter indicates a current is flowing. An unregulated supply's output voltage should fall as load increases. Make appropriate corrections to meter ranges, and proceed with the test.

If very accurate results are required, the patch-panel input arrangement simplifies the connection of outside meters. These terminals are also handy for attaching an ac voltmeter or an oscilloscope.

The fine load control is used at very low supply voltages, and for zeroing in on preferred voltage or current values when making tests with accurate instruments.

Fig. 5 shows the results of a power supply test. It was a good workout for the load box too, which was used far beyond its ratings.

The upper line is the voltage found at the rectifier output terminal. Regulation here is not good. The lower line shows the regulating circuit output. The regulator tube's 26 watts maximum dissipation will not be

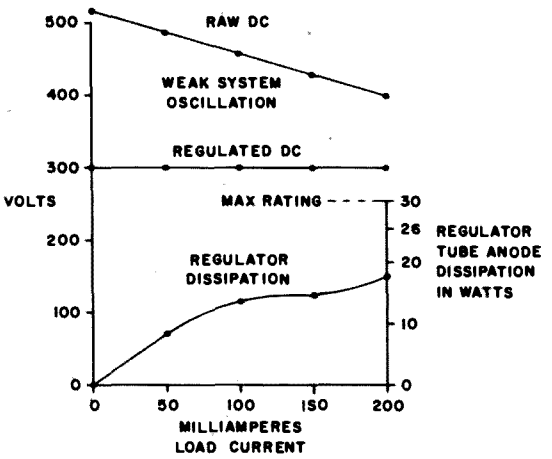

Fig. 5. Test results taken from a regulated power supply, showing regulator dissipation, and regulation well into the anticipated overload region. A few minutes work!

exceeded in normal operation (150 ma), and there is reserve against aging and overload. Looks like this supply should be reliable for long periods of time.

Well, now I guess I'll have to make up a solid state load box!

... W1EZT■

A Directory of American Open Repeaters

An up to date listing of all the open repeaters from coast to coast with information about access requirements where applicable.

Editor's Introduction

For some time now, several people have been independently working toward the preparation of a complete and accurate listing of open VHF FM repeaters in use throughout the U.S. and Canada. As the recent editor of FM Magazine, I have been busy for the past year gathering information by mail from repeater owners who mailed news of their accomplishments to me for incorporation into that journal's periodic directory. Then, a few months ago, I had the opportunity to make several trips across the country by car—which allowed me to personally check the status of repeaters far and wide.

Before starting on my cross country jaunt, I equipped myself with a high-power Varitronics rig and lots of blank paper. Then I proceeded to travel from California, through Nevada and Utah, and returning down through Colorado and other routes through Wyoming, Utah, and Nevada. A week later, going through Arizona, New Mexico, Texas, and Oklahoma, I stopped in Oklahoma City to get a variety of crystals from Sentry for my Varitronics unit, then proceeded through Kansas, Missouri, Indiana, and Illinois.

A short time later, I left the Chicago area and traveled east through Michigan, parts of Canada, New York, and many of the New England states. As a result of these ventures, I was able to glean a great deal of first-hand information about repeaters. The culmination of the records I kept on the trip is reflected in the following repeater directory, which is itself a detailed work containing (1) updated information from FM Magazine, (2) the results of a 73 Magazine survey, and (3) the dedicated contributions of Rick Zach WB2AEB.

Last Minute Notes:

1. The two Hartford area repeaters are off the air due to continuous malicious interference. A 450 repeater will replace the two defunct 2 meter machines . . . W1VVK.
2. Add this repeater to directory:
   WA2UWC Greenbrook, NJ 146.34 to 146.94.
   Machine has sexy female voice for ID . . . WB2AEB.
3. At Potters Peak,near, Wilkesboro, NC, a 6 meter repeater (W4DCD) is now in operation:
   52.78 input get you a 400W signal on 52.525 MHz.
   A 2 meter system is cross connected so that 146.42 MHz is repeated to 52.525 and 52.525 is repeated to 145.05. No tones required. Coverage is 125 miles, unit-to-unit.

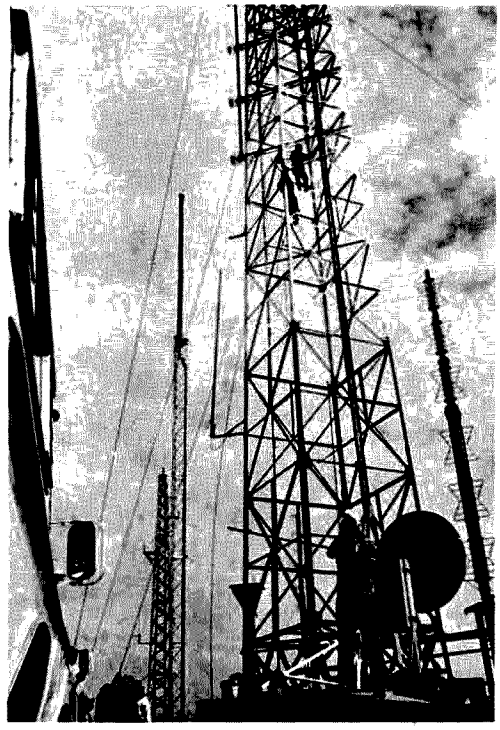
by Rich Zach WB2AEB

a word about repeaters

The trend for the future seems to be to use a compatible deviation of both narrowband and wideband rigs by using a wideband receiver and an 8 kHz transmitter at the repeater site.

Many amateurs would like to get involved in FM repeater operation but cannot do so due to a lack of information on local repeaters. We would like to remedy this situation, and thus this directory of open American repeaters is being published. Following is a list of a good number of FM repeaters in the U.S. and Canada. If you know of any other repeaters, or have corrections or additions on the listed ones, please send this information to the editor, to be used in the next update. When giving a report on a repeater, please include the following information (for *open* repeaters only, please):

- ★ Repeater call letters
- ★ Location of repeater
- ★ Elevation of antennas
- ★ Whether wide or narrowband or both
- ★ Inputs and outputs
- ★ Coverage area
- ★ Other features such as open dial or touchtone autopatch, tone burst (CTS will not be listed because this qualifies repeater as being closed).



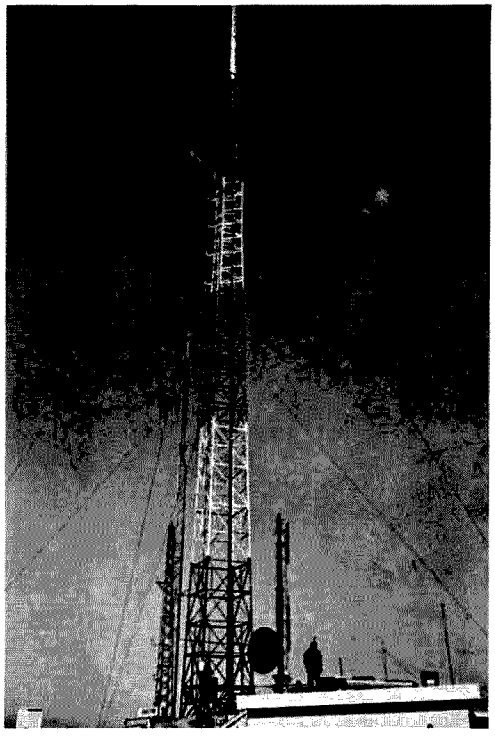
Please be absolutely sure your information is correct and that the repeater is open for use by all radio amateurs. If you see a closed repeater listed, please notify the author immediately.

Needless to say, this directory will be useful not only to the new FM ham, but it will be a good tool for repeater organizations. Much thought on regional and national trends goes into the design of a repeater.

In contributing to this directory, I have found some similarities, some contrasts, and some interesting trivia about FM and repeaters which is not shown on the list itself. You will find that different areas have different repeater outputs and deviation settings. As an example, Florida and Pennsylvania are strongly for narrowband repeaters with .76 out; New York, New England, and most of the rest of the country are strongly for .94 out and wideband. In a metropolis like New York, a ".94 out" repeater would not even be considered due to heavy simplex traffic in that area. Seven-six is used here. Canada tends to favor another input frequency: 146.46 MHz.

The trend for the future seems to be to use a compatible deviation for both narrow and wideband rigs by using a wideband receiver and an 8 kHz transmitter at the repeater site. There is a strong trend for the use of Touchtone autopatch (automatic phone patch) and dial autopatch to a lesser degree. The linking up of repeaters (via UHF "trunk lines") is gaining popularity but not as fast as autopatch. An east coast repeater link-up is slowly growing, but it will not be completed for a few years yet. Another popular practice is to use half-second tone bursts to activate the repeater. Due

to geographical overlap of two repeaters' inputs, you may select which repeater you go through by simply using different tones.



In Chicago, you can pick any of several remote receivers for the big repeater by switching tones. Tulsa has a number of remote receivers for its repeaters, too. However, it uses an automatic receiver voting system which selects the strongest signal then links it up to the transmitter site on top of the National Bank of Tulsa. This is purely a diversity system and tone bursts are not used here.

In some areas, quiet hours are observed. The Albany area is a case in point. It is mutually understood that no repeater transmissions should be made after 2300 hours so that 24-hour-a-day monitoring can be achieved. Other areas use a system similar to this but use a tone burst to open up the monitor's receiver. Many volunteer fire departments use this type of monitor receiver in each of their members' homes.

If you're interested in trivia, the average trustee of a repeater holds an Advanced Class license with Technician class running a close second.

If you like to do things a bit out of the ordinary, take a lesson from two other FM'ers. K2GUG[1] has installed a repeater in a Cessna 180 and W5DFQ has his repeater in a Jeep. K2GUG's is an independent repeater while W5DFQ's can either feed into the Tulsa system or act as a separate repeater.

When it comes to the actual makeup of a repeater, it seems as though GE Progress Line gear is used just a hair more than similar Motorola equipment. This point is the subject of a number of friendly on-the-air rivalries, but in all honesty, this is what a recent poll brought out. Antenna systems are almost always the same. The bigger repeaters tend to use either the Omni-6 by Prodelin the Super Stationmaster by Communication Products Company. These antennas are the undisputed kings of 2 meters FM (with both going for over $160, they had better be!). They are 20 ft omnidirectional antennas which provide 5.8 dB gain in *all* directions. When a repeater group cannot afford one of these gain antennas, generally they use an antenna similar to the Diplomat by Mosley. This type of antenna is a 5/8 wavelength groundplane which provides 3.5 dB gain.

Some repeaters use one antenna for receiving and another for transmitting, but the more well-to-do repeater outfits use the same antenna for both functions simultaneously. This can be achieved through the use of diplexer cavities. You guessed it. . .diplexers aren't exactly dirt cheap!

[1] *QST*, August, 1969, Vol. LIII, No. 8, p. 89 (Bill Smith's "The World Above 50 MHz")

AMERICAN REPEATERS (OPEN)

Listings in this directory are alphabetical by state, area of coverage. This concept (as opposed to a listing by actual repeater location) allows mobile operators to determine with ease the repeaters available for use along any cross-country route.

ALABAMA

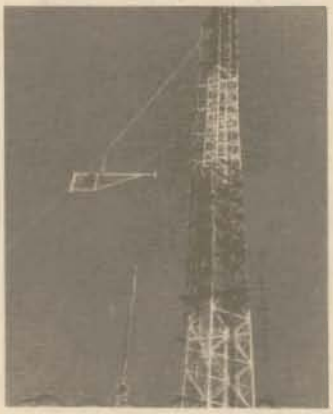
W4RFR (wideband)	146.34	146.94
W4VO (Northeast Alabama, Northwest Georgia)	146.34	146.94

ARIZONA

Prescott area

W7AJU (wideband)	146.34	146.94

Phoenix area and extended regions adjacent thereto



WA7CEM (wideband)	146.34	146.94

Ariz. Rptr. Assn.

Sierra Vista

WA7KYT (wideband)	146.34	146.94

Cochise Amateur Radio FM Assn.

In this photo, a tower arm is being hoisted to the top of the commercial tower where the W7CEM repeater (Phoenix) is located. The arrow shows the almost microscopic figure of one of the braver hams of the repeater group, who will affix the antenna to the arm and fasten the arm brace securely to the tower. The Phoenix "machine" gives a range of approximately 50 miles. (See coverage map.)

ARKANSAS

WA5SNO (Fayetteville; narrowband)	50.50	50.40
W5DI (Little Rock and vicinity; narrowband)	146.30	145.50

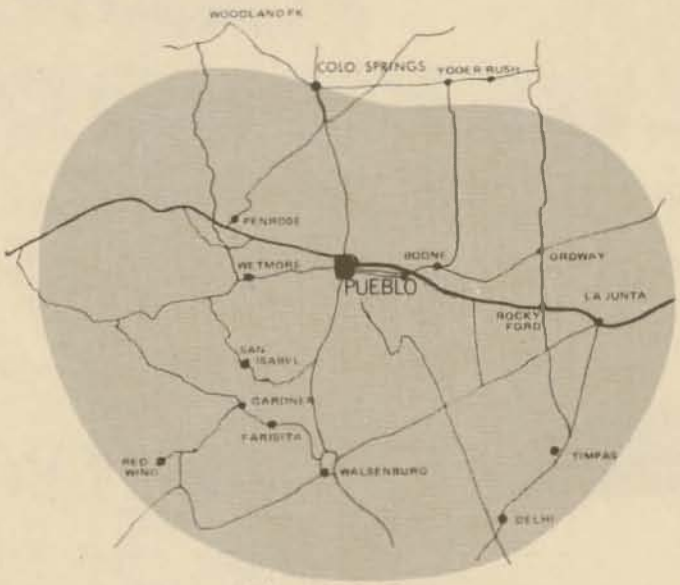
CALIFORNIA

Los Angeles area

W6FNO (Radio Ranch)	146.82	146.70

Wideband. Transmissions limited by timer to one minute each. Covers San Fernando Valley, San Gabriel Valley, Pomona Valley, Paradise Valley, most of Los Angeles County, Orange

The Radio Ranch repeater (146.82 to 146.70) in the Los Angeles area has a wide range of coverage with a pattern shaped like a wedge. Terrain features make limits sharp, so that signals drop off suddenly, regardless of mobile power and antenna type.



County, parts of Riverside County, and southern third of San Bernardino County. Elevation: 3000 ft. Separate receive and

transmit sites. 35W out. User must whistle (1750 Hz) to activate repeater initially; carrier-operated unless input channel vacated for three minutes.		
WA6UJS (Radio Ranch)	52.76	52.525
Narrowband; 3 kHz in/out. Link planned for coverage from Northern California to Mexican border.		
WA6VFO	146.52	147.18

WA5JDZ (Albuquerque)	146.34	146.94
WA5GFS (Portales)	146.34	146.94

Atop 10,700 ft Sandia Crest in New Mexico, Dr. Phil Dater takes a day off from his medical practice to hang a 450 MHz antenna in 20-below weather. The Sandia Crest repeater, WA5JDZ, provides coverage from Santa Fe to Socorro and interlinks with two other repeaters, WA5MQ and WA5KUI. The coverages of the three are shown in the map.

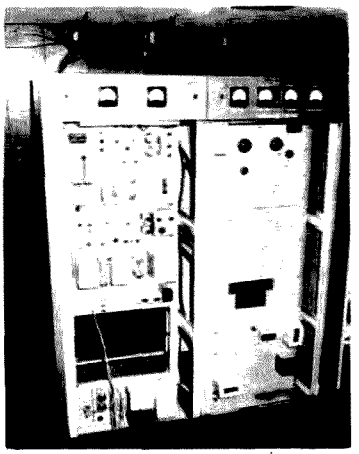
K5CQH (Albuquerque)	146.46	147.06
WA5DMQ (Roswell)	145.50	146.50
W5PDO (Los Alamos)	146.34	146.94
No call given (Caprock)	146.34	146.94

All New Mexico repeaters are free access (no tones) and narrowband FM.

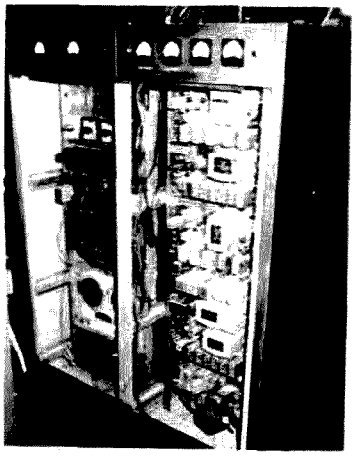
1: New Mexico Repeater System – three repeaters linked to give almost border-to-border coverage.

WA5JDZ, Sandia Crest (near Albuquerque); 146.34 MHz in and 146.94 MHz out; owned by Philip H. Dater M.D., Albuquerque.

WA5DMQ, Sierra Blanka (near Roswell), 145.5 MHz in and 146.5 MHz out; owned by Ken Letcher, W5YFN, Roswell.



WA5KUI, Almo Peak (near Almogordo), 146.34 MHz in and 146.94 MHz out; owned by Donald Scott, Alamogordo.



2: W5PDO, club station, Los Alamos Radio Club, 146.34 MHz in and 146.94 MHz out; covers 50 mi. radius of Los Alamos.

3: WA5VKY, club station, Amateur Radio Caravan Club of New Mexico, located at Sandia Crest (10,600 ft elevation), 146.46 MHz in and 147.06 MHz out; covers presently about 50 mi. radius of Albuquerque; however, the transmitter is copyable throughout New Mexico and into adjoining states. A better diplexer and remote receivers should give the repeater better ears and extend the coverage to about 200 mi. radius.

4: K5CQH, located in the Monzano Mountains (7730 ft elevation) about 20 miles southeast of Albuquerque, 146.46 MHz in and 147.06 MHz out – backup for WA5VKY in case it blows up. Also 147.06 MHz in and 147.72 MHz out. This one picks up a few canyons close to Sandia Crest that the Crest signal squirts across and not into.

The transmitters, amplifiers, and power supplies of the WA2UWO repeater are shown in the photograph at left. The other two-bay cabinet, pictured at right, contains the system receivers, relays, control elements, and log recorder. The ready-made commercial cabinets have the advantage of providing built-in meters for measuring all the important parameters of the repeater transmitters and receivers. The equipment shown is 100% General Electric.

FM Repeaters under fire from FCC

An FCC move feared by all FM'ers since it was first publicized in FM Magazine back in March 1968 has finally happened: The FCC has docketed a set of repeater rulemaking recommendations that are so constricting as to destroy half the repeaters in the country. What are these earthshaking comments?

1. No crossband operation. Period. This means that no one will be able to operate through his repeater from 450 MHz. This means that remote operation of transceivers will be illegal. This means that site-to-site links will be illegal, unless they are interconnected via a wire line.
2. Only one transmitter can be energized per receiver, and signals cannot be re-repeated. This means no multiple-output repeaters; no links, no cross-connected repeaters, and no cross-country systems.
3. Transmitters and receivers of repeaters will be authorized on specific subbands only. Here are the catastrophic subbands proposed:
   - 6-meter repeaters must receive between 52.5 and 52.7, and must retransmit the signals between 53.0 and 53.2.
   - 2-meter repeaters must receive between 146.3 and 146.6, and retransmit the signals on the frequency range of 146.9–147.2.
   - UHF repeaters must receive in the range of 447.7–447.9, and retransmit in the range of 449.1–449.3.

The implications of the foregoing are obvious. Prime repeaters are okay on .94, but all the .76 systems will be defunct. Talkback repeaters will be completely wiped out. The UHF transmit-receive spread is only two megahertz, which will all but eliminate all but multiple-site, wireline interconnected repeaters.

There are a number of other restrictions, such as a 600W power limit, mandatory tone access, relaxed logging. Most of the other restrictions can be lived with, but repeaters cannot survive with the restrictions as noted above.

The FCC will accept comments from individuals interested in repeater rulemaking until May 15. Let no grass grow under your feet. If you haven't already made in issue of this, do it now. Call your club together for an emergency meeting and start putting together your comments formally. Mail them (and 14 additional copies) to the FCC in Washington, D.C.

Urge the FCC to accept RM-1542 without change. It is reasonable constricting, but in the best interest of amateur radio. It, too, requires mandatory tone control, for example, but only as an alternative to continuous monitoring from the UHF control frequency. RM-1542, submitted in December 1969, asks that the FCC relax logging in favor of a "technical log." It asks that control of the repeater be permitted by tones from the frequencies of use INSTEAD of requiring a UHF monitor at a fixed control point. RM-1542 is a good proposal and it is in the best interest of the public and the amateurs. If the FCC would accept RM-1542 without change, and reject the recommendations offered in Docket 18803, repeater operation would grow and thrive, and optimum use of the spectrum would be assured.

. . . K6MVH ■

the fine points of FM peration

Richard J. Zach WB2AEB
22 Pike Place
Mahopac NY 10541

Another installment in a continuing series of FM "beginner" articles.

After you get set up on FM, you'll find that you will be doing a lot of monitoring. To the seasoned HF operator this may seem quite futile. However, with simultaneous signals FM receivers have a property of receiving the stronger and almost completely rejecting the weaker one with little or no heterodyne. Also, all FM communications receivers (except for a few pocket pager types) have a rather sophisticated squelch circuit. When it comes to receiving a weak FM signal, the modulation does not steadily decrease with the signal strength, but is nearly "armchair copy" to a critical point. Once the signal gets below this point, it drops completely out of the picture and the squelch will close. Roll all these properties into one receiver and monitoring will be a joy. When a signal is received, chances are that it will be just one clear, fully modulated voice. When there is no signal you will hear nothing but silence . . . no QRM or static, just silence.

This all sounds like an ideal situation, and it is. However, the transmitting station must do his part too. His signal must conform to certain standards. His center frequency must not be far above or below the accepted channel: deviation must not be far above or below the accepted value in that area, as well as other criteria. The only way that we can keep the operating channels clean is to

continuously monitor each other's transmissions and give constructive criticism. Actually, this is not very different from other modes.

The equipment used to analyze FM transmissions is either superexpensive or extremely cheap. If you have ever priced digital frequency meters or deviation meters, it is not hard to tell which method is the expensive one. The inexpensive method is quite simple and accurate and I claim no originality for it. The equipment described (except for the oscilloscope feature) is in operation in about 90% of all the metropolitan New York base stations. As you can see in Fig. 1, it is nothing but a switchable meter to read limiter current (signal strength) and discriminator current (frequency).

If the discriminator reads zero, the received signal is exactly on your frequency. The meter can be calibrated in kHz off frequency by experimentation. For the initial setup you should use a good frequency meter or a station that is the frequency standard for your area (usually a repeater). However, make sure you know that your frequency standard is actually on frequency. Also, when giving off-frequency reports, make sure that you are on frequency, too. If the discriminator-meter needle wiggles, the received station's modulation is asymmetrical (swings more in one direction than the other) and should be corrected. Without the meter you might think that his deviation is too high due to distortion on the peaks.

The limiter current reading is only a reading of relative signal strength and should not be compared with other receivers. As an example, a typical GE Pre-Progress Line (Pre-Prog) receiver may give a reading in the teens for an excellent signal. A Progress Line receiver may show a 100 μA reading for the same signal. These readings vary even in identical receivers. In other words, become familiar with your receiver's meter and express the signal's figure of merit accordingly. When receiving a strong signal, check to see if the limiter current changes with the modulation. If it does, this is a sign of AM'ing and should be looked into.

Walt Guderian (WB2RAA) showed me a nice little trick using the oscilloscope. Almost any inexpensive scope will work. Connect the vertical input to the discriminator jack and put a slow (under 100 Hz) sweep on the horizontal plates. When no signal is received, you will see a pattern like in Fig. 2a. This is just noise on the discriminator. Receive a full-quieting carrier and you will see a flat line. If you see sine waves like that of Fig. 2b, this can be a low frequency MCW ID on a repeater or hum in a transmitter. Through Lissajous figures you can also try to determine the frequency of the audio signal. Its most important function, however, is to help locals to roughly set their deviation level. Again, a standard for calibrating your

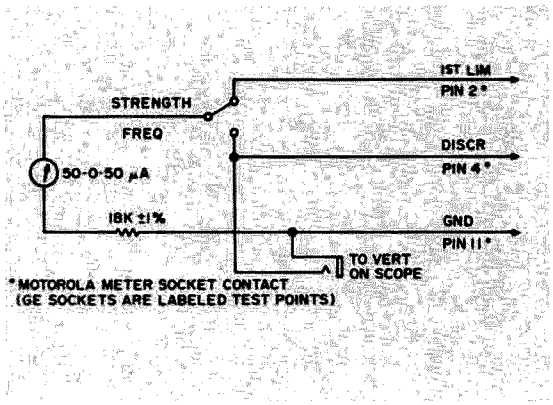

Fig. 1. A zero-centered, sensitive meter can be switched from discriminator to limiter test points to monitor frequency and signal strength. Scope output monitors discriminator continuously.

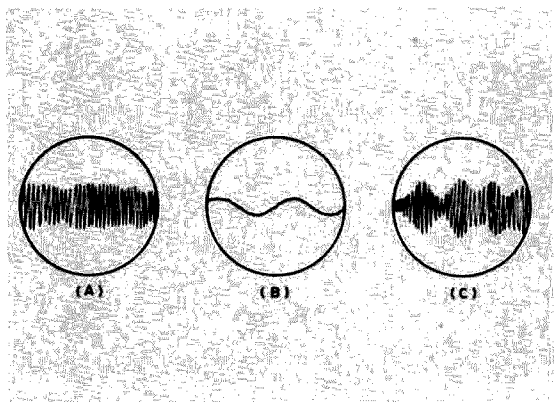

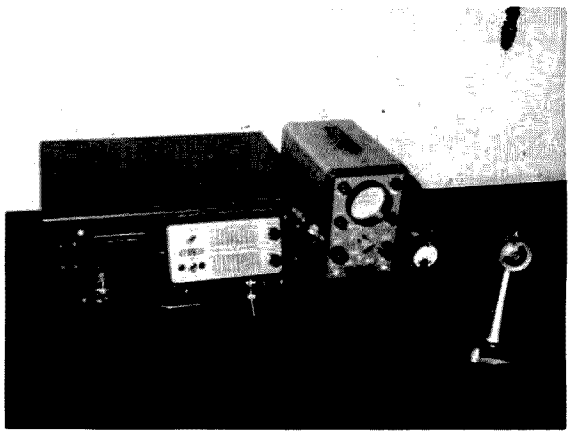

Fig. 2. Swept scope traces show discriminator noise (a), low-frequency products, such as PL, on a signal (b), and a fully modulated, strong signal (c).

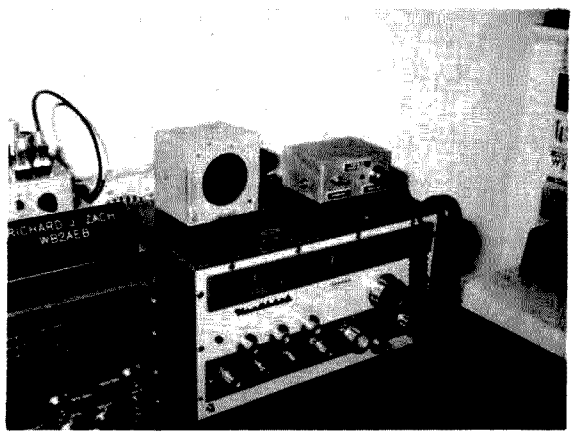
scope could be a fully modulated repeater output signal. Knowing that a repeater has been set up for 12 kHz deviation, for example, you would adjust your vertical gain so that 12 kHz would read 3 cm (4 kHz/cm) on the CRT while a fully modulated signal is being received. It should be noted that by "fully modulated" we mean modulated to the deviation limits acceptable by the repeater. By approximation, you can estimate the unknown deviation being transmitted. A full-quieting signal with good modulation should look something like Fig. 2c.



Another gadget which quite a few FM hams employ is a remote control unit. Many a non-FM ham at one time or another has thought of doing this, but abandoned the whole idea due to receiver drift and the need for many controls. To remote an FM rig by wire, it is simply a matter of bringing out the mike, PTT, and speaker leads. With Motorola and GE, this is a "no holes" modification if it can even be called a modification. I remoted my GE Progress Line through the microphone jack. The basic modification to the 4EC29A front-mount control head is to connect a 2.2 kΩ half-watt resistor from pin 4 on the microphone jack to pin 11 on P701.

As an optional convenience, install a small SPDT switch on the side of the control head. In case you want to hear only the remote speaker and not the local, this switch disconnects the local speaker and puts a resistor load across the output transformer. Since I had an abandoned rotor wire already going from the rig to the shack, I used that. The 100 ft length did not cause any loss or hum problems. The connections on the GE microphone jack are the following:

Pin 1 - mike low (grounded in transmitter), voice coil low
Pin 2 - mike high
Pin 3 - PTT high
Pin 4 - voice coil high
Socket - ground

The complete VHF–FM base station in use at WB2AEB. Note added muting switch on side of control head and external metering jacks.

The remote unit can be tucked into even the most crowded shack. Note remote speaker muting switch (quite handy).

To transmit, ground pin 3. To remote a Motorola rig, the procedure is the same but the leads can also be brought out from the power and metering jacks. (These might vary from rig to rig so consult a schematic for connections.) As you may have guessed, the squelch and channel selection must be made at the rig itself, but with work these can be remoted too.

In your own area, a special or unique feature might be in operation. Some groups have a system where when a special audio tone is received, an alarm is set off denoting a communications emergency. Other outfits have an automatic phone patch (called autopatch) built into their repeater. Many autopatch-equipped repeaters are now converting to Touchtone because of its versatility for dialing and control. As you can see, the needed accessories can vary widely.

Although not usually considered accessories, manuals, schematic digests, and other literature are vital to the FM ham. Since these rigs were designed for business usage,

EL 3401A/54

New Norelco Video Tape Recorder

AT A NEW LOW PRICE OF $585

This VTR will accept any composite video signal (random, 2:1 or EIA) fed from a single coaxial cable, TV camera, etc. These units are brand new, complete with head, and instruction manual in original factory cartons & use 1" tape. Original list price was in excess of $3000. Limited quantity – shipped by truck or REA, transportation charges collect, approx. wt. 100 lbs. Check with order only. $585 net. For additional information, request our free flyer 970J2.

If you own a GE rig of the Pre-Prog era (1949 to 1955), General Electric has two books available which were written especially for the amateur. Volume I covers low-band (25 to 50 MHz) and mid-band (72 to 76 MHz) rigs. Containing information akin to the Motorola book, this publication has the GE number LBI-3883. Volume II (LBI-3884) has information on high-band (150 to 174 MHz) and UHF (405 to 475 MHz) rigs. Both books are $4.50 each and are obtainable directly from General Electric Company, Box 4197, Lynchburg VA 24502. If you want a Progress Line manual, it will cost less than $2 and is written for your specific rig. General Electric also publishes "Datafile" bulletins. These are excellent booklets on such topics as "Fundamentals of Solid-State Logic Circuits," "VHF and UHF Propagation," "Radio-Frequency Interference in Two-Way FM Radio," and others. I would heartily recommend getting Datafile Bulletin 10006-6, "I-F Alignment of Two-Way Radio FM Receivers." This book takes the "twiddling" out of the ticklish job of FM i-f alignment. Undercoupled, critically coupled, and overcoupled i-f filter alignment are discussed. Of the Datafile series, this is the most expensive volume, with a price tag of $1.50.

For a complete listing of all GE publications of interest to the ham, write for list ECP-227. It's free.

Howard Sams puts out the *Communications Equipment Schematic Manual.* This covers mostly late model transistorized rigs, and is divided into five sections: Basic Theory, FM Transmitters, Double Superheterodyne Receivers, Power Supplies, and Alignment Procedures. The $3.50 book is obtainable from your local radio store. For those of you who are getting serious about putting up a repeater, Ken Sessions (K6MVH), editor of 73, has written the *Radio Amateur's FM Repeater Handbook.*

Until recently there was also a magazine which specialized in FM operation (called *FM Journal.*). This magazine is no longer in business, but the editor and publisher have joined the 73 staff – a fact which should serve to keep this magazine in the forefront of the FM activity. ... WB2AEB ■

HOW TO "MEGGER" YOUR ANTENNA

A simple, proven way to periodically check the performance of a transmission line/antenna system which can uncover faults not indicated by SWR measurements.

Meggering of antenna arrays and rf transmission lines is a procedure frequently performed by commercial and military activities during the construction or preventive maintenance cycles. It is rarely done by amateurs, and yet the procedure and equipment are relatively simple and the test can reveal a great deal about the condition of an installation. It is not a simple ohmmeter check as it may appear to be at first glance. This article explores what function a "megger" check accomplishes, how to perform the check, and the details of some equipment which can be used.

Insulation Resistance and Cable Quality

Rarely does any amateur have a station installation where the transmitter output (or receiver input) is directly wired to the antenna transmission line which, in turn, is directly wired to the antenna. More typically an installation will look somewhat like **Fig. 1** if one traces in detail the signal flow throughout. Obviously, a great many more connectors, switches, and accessory items are involved than is readily apparent. Also, in any real installation, the cabling goes through many bends, and outdoors, is exposed to a variety of environmental factors.

Most amateurs rely upon an swr meter to give them an indication of how the overall

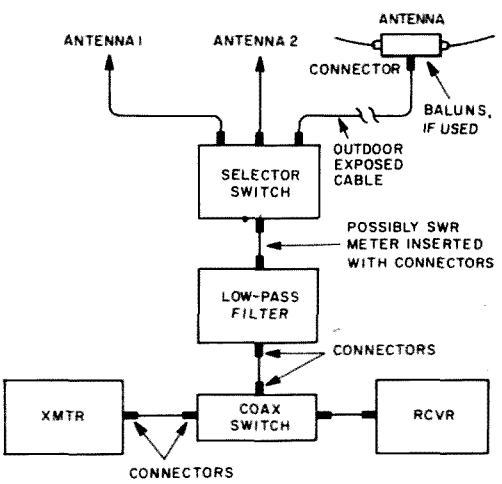

Fig. 1. Actual transmission path in usual installation can involve going through a number of connectors and accessory devices.

antenna system is performing and whether any damage to the system has taken place. On a day-to-day basis, the use of the swr meter for this purpose is probably valid. Ideally, one should also have a method for constantly checking the overall signal *attenuation* throughout the antenna system. It must be remembered that an swr meter, depending upon its method of operation, measures only the impedance ratio or current/voltage phase relationship in a transmission line. Attenuation can build up through cable deterioration, connector losses, leakage resistance, and component deterioration in accessory or switching devices—and this buildup will never be apparent on the swr meter reading. More than one amateur operator (and even quite a few professionals) have read a 1:1 swr at the transmitter and gone happily, but often unsuccessfully, operating when the swr at the antenna was quite high.

To measure attenuation correctly, one should inject a signal of known amplitude in the transmission line system and then measure the output at the terminated end of the system. Such a measurement is generally made when a commercial installation is initially put into operation, and it would be a good idea for amateurs to follow the same practice.

Unfortunately, such measurements are not convenient to make and one hardly wants to be continually faced with the problem of gaining access to the antenna end of the transmission line to connect a signal generator or terminated voltmeter to it. There is no simple in-line form of meter, such as a swr meter, which will check attenuation. The megohmmeter (or "megger" as it is incorrectly but commonly called), however, is commonly used to detect the change in insulation resistance in a transmission line system. Decreasing insulation resistance is a positive sign that leakage resistances and other dissipative effects are developing which can increase the attenuation in the system.

Megohmmeter Usage

The megohmmeter is simply connected between the two terminals of the transmission at the transmitter. The antenna end of the transmission line must not present a closed circle. This is no problem if a dipole antenna is used; nothing must be done; it is simply left connected. If a loop type of antenna is used, one of the two transmission line connections must be broken to effect an open dc loop.

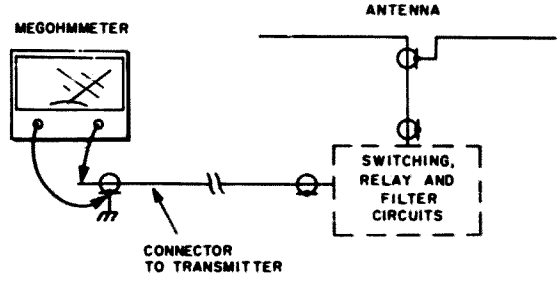

Fig. 2. Megohmmeter check is performed as simply as an ohmmeter check, but its meaning should not be confused with that of a simple ohmmeter check.

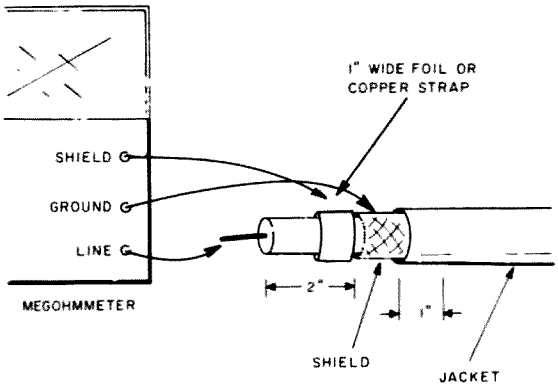
At first glance, the procedure used may seem to be that of a simple ohmmeter check (**Fig. 2**), and indeed that would be the case if an ohmmeter were used. The megohmmeter differs from an ohmmeter in several respects, although it is basically also a simple instrument. The maximum resistance range on the usual ohmmeter is a few megohms. The ohmmeter impresses a relatively low voltage across the resistance to be measured (perhaps 1-3V when used to measure a megohm). The megohmmeter, on the other hand, reads resistance ranges higher than 1 GΩ (1 gigohm, or 1000 megohms), and impresses a voltage across the circuit being tested equal to or above the voltage at which the circuit actually operates.

In practice, megohmmeters which place 50-500V across the output terminals are used to test rf transmission lines. Various leakage resistance effects can be present which will not be apparent unless at least such a value of voltage is used. No harm can usually be done using these voltage levels since even small cables such as RG-58/U are rated at 1.9 kV. However, one must also take into consideration the maximum voltage rating of the relays, filters, etc. present in the entire transmission line system. Usually, these voltage ratings will be found to be the

limiting factor, although rarely will they not allow the use of up to a 500V megohmmeter.

What insulation resistance or megohmmeter reading should a good transmission line system present? Ideally, one should "megger" a system when it is initially installed and when actual attenuation measurements are made. With a good dry system, insulation resistance readings of at least 100–200 MΩ should be possible. Then, if readings are taken periodically–monthly or whenever some problem is expected–one has a reference reading to compare subsequent readings against. If no attenuation readings are taken, the minimum insulation resistance which should be considered satisfactory is 50–100 MΩ. During wet weather or damp conditions, resistance readings may drop to the low end of this range. However, readings much below 50 MΩ or, especially, a continuing series of decreasing readings which are taken under similar conditions indicate that some component in the transmission line system is going bad or that some connections were poorly made and moisture is entering the line.



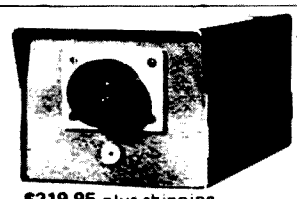


Fig. 3. Megohmmeter connections as set up for accurate insulation resistance measurement on coaxial cable. For most amateur purposes, shield connection is not necessary.

Megohmmeter Construction

A megohmmeter presents a potential of 50-500V across the circuit to be tested, but its internal resistance is in the order of megohms and little current flows in the circuit under test. Aside from this, a megohmmeter operates on the same principle as a regular ohmmeter.

COMPACT, HIGH QUALITY TELEVISION CAMERA for video or rf channel use. 25 transistors, 18 diodes, 500 line resolution. Dimensions 4 1/8" x 5 1/4" x 12". F1.9, 25 mm lens included. Ideal for ATV or closed circuit. Order yours now!!

There are both mechanical and electronic megohmmeters. The former type uses a hand crank to turn a dc generator and it incorporates a special differential meter movement. New instruments of this type are somewhat expensive but if one can be found on the surplus market, it would certainly prove to be a complete, self-contained test unit. Three terminals will be found on these instruments, labeled *ground, line,* and *shield,* as shown in **Fig. 3**. Normally, the ground connector is simply joined to the shield of a coaxial cable and the inner conductor of the cable to the "line" terminal. If, however, accurate readings *over* 100 MΩ are desired, a leakage shield must be placed around the cable end as shown. This shield is insulated from both conductors of the cable under test and connected to the *shield* terminal on the megohmmeter. It prevents surface leakage at the end of a cable that influences the taking of accurate readings above 100 MΩ.

Many forms of electronic megohmmeters are available and utilize ordinary meters rather than special differential types. One such megohmmeter, manufactured by Reiner Electronics (which also may be available on the surplus market), type CALN-60089, is schematically shown in Fig. 4. The circuit is relatively simple, the batteries make the unit portable, and the 50V test voltage level is suitable for most amateur needs.

A 67.5V battery supplies the current to the circuit under test into the grid of the amplifier tube. The meter responds to the total cathode current which flows in the tube. Since the tube is operated in a positive grid current region, the meter response to the current flow will follow a logarithmic response. Thus, the following meter readings in microamperes will correspond to the following resistance values: 0 μA to infinity, 3 μA to 10 GΩ, 20 μA to 1 GΩ, 27 μA to 100 MΩ, 50 μA to 10 MΩ, 70 μA to 1 MΩ and 100 μA to 0.0Ω.

Operation is simple: The ground and test terminals are shorted directly together and the *zero adjust* potentiometer is used to set the meter at 100 μA or 0Ω. The switch in series with the battery may be a pushbutton type if desired since the tube is an instant heating type. Other high-gain tubes may also be used but the meter scale will then require recalibration by using resistors of known value. The meter itself may be any conventional 100 μA type or even a similar range on an existing VOM. Some initial difficulty may be found in obtaining the one 500 MΩ resistor called for in the circuit. The resistor can be built up from a series group of lower value units, but ordinarily resistors up to 22 MΩ are available. With some diligence, however, resistors with values of 100-300 MΩ can be found, especially from the larger supply houses. Some suitable types are Aerovox CE500 series, Caddock MG780 series, and Dale MC-2 series.

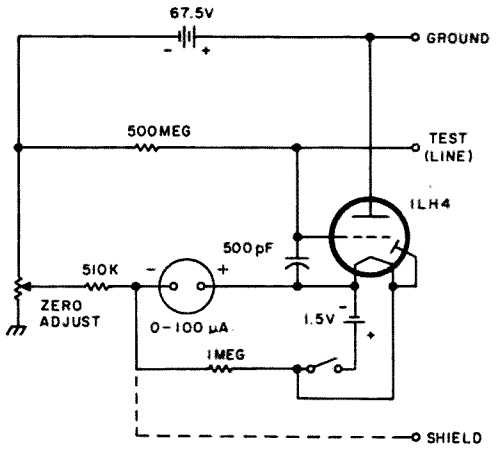

Fig. 4. Schematic of simple portable electronic megohmmeter which will measure up to 1 GΩ.

A *shield* terminal can be brought out, if desired, from the negative meter terminal as shown in **Fig. 4**. As explained before, however, such a connection only has value if one wants accurate readings above 100 MΩ. Generally, relative readings and particularly noting their change as periodic tests are performed will suffice. If the unit is constructed in a metal enclosure, the *test* terminal must be a good quality feedthrough; otherwise its leakage resistance will parallel that of the circuit being tested. A Teflon insulator is preferred.

Lastly, one should never hold the test prods, if such are used, across the circuit tested; they should be clipped on. Not only is this a safety precaution, but body resistance can drastically affect readings when one is performing measurements in the high-megohm range.

Toned Repeaters

I enjoyed the article *Encoding and Decoding in FM Repeaters* in the February issue of 73. In areas with overlapping coverage from one or more repeaters some sort of tone coding certainly would be desirable, but I fear we might end up with incompatible systems if we don't agree on some master tone system soon. What good are repeater crystals without the proper entry tones?

Touchtone is certainly going to become even more of a standard than it is today. Why not use the four tones from the Touchtone high group for tone-burst systems. Anybody traveling from area to area would then need only his Touchtone pad rather than an audio VFO!

For your repeater list the only machine operating in the greater Vancouver area is VE7ACS 146.34 to 146.94.

Darrell Wick WB6MAY/VE7
President B.C. F.M.
Communications Assoc.

There should be standards for Touchtone as well as tone-burst entry. The TBE standards are already reasonably well established. See, for example, "A Look at Amateur FM Standards," by Robert Kelty WB6DJT, 73 Magazine, March 1970.

I have written a letter to Robert Booth, Jr. of ARRL, as follows:

> "Please be advised that I am not a member of the ARRL for specific reasons. Consequently, I wish to specifically point out that any inference that I am represented by the ARRL in petitions to the FCC for rule changes is not in order.
>
> "I believe it would be appropriate for the ARRL to specify the number of LICENSED MEMBERS represented by the ARRL in each petition tendered to the FCC."

This was brought about by the latest idiocy of the ARRL, to open all of the 2 meter band to the Technician, as well as a part of the 10 meter band. What kind of thinking is this? Incentive licensing to upgrade the amateur and now a program to reverse the process and made even the General license of reduced value. Looks like the ARRL circulation has fallen off badly.

Of course I have written to the FCC to this latest ARRL petition, but the way things have been railroaded I suppose it is too late to do anything about it.

I have pointed out to the FCC that petitions presented by ARRL should specify the current number of licensed members represented by them. The number should not include libraries, business corporations, SWL and other clients who do not have an interest in the matter.

William J. LaHiff W2IVT

Death of a Friend

I have a homebrew linear amplifier that runs 3 kV on the plates of the finals. Last night I left the back cabinet door open to make a bias adjustment. What I didn't know was that the contacts on the plate supply relay welded shut. About an hour before I came down to adjust the 80 meter tank, I heard a tremendous commotion downstairs. My father ran down, saw my rig smoking and popping horribly. He ran into the utility room and popped the 220 breaker to the B+ supply. I ran to the linear, looked inside, and saw my cat splattered all over the inside of the cabinet. The whole house was pervaded with a sickening smell for days. That cat looked like she had been napalmed; she was really roasted. It took three hours of nauseating work to clean the rig out. Burnt hair and flesh don't clean off well.

What would have happened if I had grabbed the plate caps working on the rig? A quick word: *Don't* use a toggle switch to control the plate supply! Use interlocks! Use some kind of high voltage indicator!

With several thousand volts, *you don't get a second chance!*

A Sorry W9

Apollo 12 Special Certificate

Here is a copy of the Apollo 12 special certificate which our club station is issuing to all amateur stations contacted during launch day. A total of 1285 QSOs were made on the 80, 40, 20 and 15 meter bands. Seven transmitters were utilized in the CW and SSB modes.

Our club station is located approximately 10 miles south of the Apollo launch pad. This affords us an excellent view of the liftoff. Transmissions from the club station start shortly thereafter. This activity started with the launch of Apollo 7 and we have mailed out thousands of similar certificates. It is the club's way of sharing with other "hams" the events of that day.

Operators at this station consist of NASA, Air Force, and contractor personnel. This station is often activated on weekends and can be found at approximately 21.340 MHz.

Kennedy Space Center FL

Advanced Class Course

I want to add my thanks to you for the excellent series of articles you have had in the past two years on advanced radio theory. I got started in ham radio as a Novice with my high-school age son in January 1967. In December 1968, having studied your articles, I made the Advanced. Last December I passed the Extra.

With your articles, anyone can pass the theory for these higher class licenses. They not only will get a better (?) license, but they will know theory that they can apply in the fascinating aspect of building and repairing ham gear.

In addition to using your articles for the license exams, I have used them as a basic text for the course in advanced theory I have been teaching for our radio club.

The higher code speed came easy through my activity in the Army MARS program. Once again, thanks!

Bob Malmquist WA9TTS
605 Vine Street
Morris IL

The Truth Hurts

Once again 73 magazine has set a new standard for an amateur oriented magazine: truth in advertising!!! I refer to the "30 Back Issue Bonanza." When you said the issues were packed in sloppy bundles, you certainly weren't fooling! I got my bundle today, the box was split down the seams, and wrapped in old bailing wire. The box (?) was also marked "Received Damaged–Kansas City, Mo." I have received numerous packages that have been promised to arrive in good condition and haven't–but this is the first time I have been told to expect a bundle in bad condition. 73, I salute you for truth in advertising! By the way, I think the mags. are great. They're worth their weight in gold!

Russ Williams WA6MWY
1312 Lawrence St.
El Cerrito CA

A Political Approach

Have you listened to the 7200–7300 kHz area of the forty meter band lately at about 0300 or 0400Z, especially on a weekend? It has become an international shortwave broadcast band at times in the evening hours.

Allow me to introduce myself. I'm one of those terrible young whippersnappers who think they know everything. Seriously, I'm 16 years old and fed up with that mess on the upper end of the 7 MHz band. It has fewer and fewer amateurs and more and more broadcasters almost every week, which is no way to run an airline, or to convince the next ITU conference on allocations that we really need those frequencies either.

It is rapidly becoming apparent that the ARRL Intruder Watch, while it proved that these schnooks were beaming at the U.S. and lying through their collective teeth when they said they weren't, did next to or absolutely nothing towards convincing officials to do anything about it. Doubtless most officials have forgotten about it (albeit with effort) to take some decisive action towards getting a few bureaucratic types to stand up and maybe even do something, for the first time in their lives. Decisive action must be taken if we are to be able to really use this part of the forty meter band.

Political action has more effect on government-involved people (including FCC and the international organization known as International Telegraphy Union) than any other kind. And of the most effective of political action is to indulge in the freedom of the individual in this country, which, if I may add, happens to be the best on this earth, bar none. This method is simply *writing.* If every other amateur in the country wrote ITU and FCC, each would receive about 150,000 letters. Imagine the impact of that! Or write Barry Goldwater. He would appreciate the situation, being a ham.

But a massive write-in program needs publicity. So, why don't 73, CQ, Ham Radio, and QST publicize it? No reason against it at all. In fact, Mr. Green, if you used "de W2NSD" and Mr. Huntoon used his editorial column, a great deal of publicity could be obtained, as both columns are controversial and tend to be widely read.

An all-out effort by all these magazines providing a united front of amateur radio to the world, and a vast write-in campaign such as I suggested would lend quite a bit to the appearance of amateur radio in the world. It certainly would promote a lot more respect of amateur radio. And isn't it simply for a lack of respect for the amateur bands that these broadcasters can do this?

Mark Hinton WA3IVW
2404 Stratton Drive

CB vs Hams

As I'm writing this letter, several people are out in the damp, foggy night and are hunting for a three year old boy. It is 1:30 a.m. The child has been missing since 4 p.m. yesterday. The following is an actual account of what happened only a few hours ago.

As you can see from this letterhead, I attend Lehigh University in Bethlehem, Pa. I was studying calculus (we all don't get drunk on Saturday night) when one of my schoolmates knocked on my door and asked me if I knew where the Lehigh Valley Shopping Center is. He told me that a three-year-old had been lost there, and he and another fellow were going to see if they could be of any assistance to the search party. I volunteered to go with them.

Since we were all strangers in town, we had to call the police to determine where the shopping center is (we all don't hate cops, either). It turned out to be four miles away, and since we couldn't find anyone with a car, we decided to walk.

After about an hour and a half, we reached the shopping center. The first thing I noticed was the abundance of CBers. The CB–ham rivalry never actually hit me because I was concerned with the child's being lost.

The police had just finished searching the department store the child was last seen in and they gave out the general areas to be searched. Our group took one area and we combed several square blocks. About 1 o'clock the walking search was given up. All the area within a 1½ mile radius of the shopping center was searched with no luck, so the search was to be resumed at dawn.

Since it was past one in the morning, and we had a four-mile walk back to the dorm, we bummed a ride with someone high up in the CAP. While riding back, the CAP official made use of his radio, a converted CB rig.

I can't help thinking that if there had been better organization, the child would have been found. There was no radio communication with the majority of walking groups. The CAP seemed to have the most effective communications. The only other groups were the police and CB. If someone could have coordinated these different services there would have been a good chance of finding the child.

By now you are probably wondering what role ham radio played in this. As far as I can tell, there were no hams present. What good does all that operating skill do with no hams there to use it? The ham magazines print plenty of stories telling how hams help in emergencies. What about his instance?

What I am proposing is two different types of emergency nets. The first is a long distance net on or near 20 meters (I say near because the FCC might give us a few channels above 14.5 MHz if we can prove we have an effective emergency system). The second would be a local net in the 10 meter band. This net would provide mobile and most especially portable equipment,

which is converted CB equipment. Let's face it, ham radio is lacking in the portable equipment area.

Both nets would incorporate tone signal alert type equipment. Both systems would use crystal control or at least be fixed. The clincher; the frequencies would be kept clear at all times (now you know why I said *near* 20 meters).

I'm not proposing these measures for the betterment of amateur radio–I'm merely stating that I think it should come up to what is morally obligated to do, and then worry about contests, ragchewing, DX and all the fun.

Anthony A. Parise WA3HRL

VHF FM appears to be solving the problems you mention. It has three things going for it: availability of equipment, portability of equipment, and fully channelized operation.–Ed.

Credits

In your February editorial you stated that the Department of Communications used the Buffalo petition as a foundation for Canadian repeater regulations. This is not true, and you gave Buffalo all the credit, completely ignoring the fact that it was the Toronto FM Communications Association, especially Paul Hudson, VE3CWA, who drew up a brief, using some of the information in the Buffalo petition, and submitted it through the Radio Society of Ontario and the Canadian Amateur Radio Federation to the D.O.C. in the spring of 1969.

To back up my statements, I have enclosed a reprint from the November 1969 issue of the Ontario Amateur, which is the publication of the R.S.O.

I hope that your statements will be corrected in the next editorial.

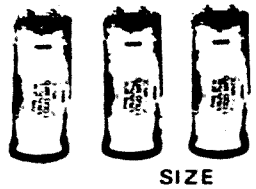
Jim McCullough VE3CSO
Treas., Toronto FM
Communications Assoc.

Neglecting the contributions of the Toronto group – and particularly the efforts of Paul Hudson – was my error. I knew that Paul had formulated the original petition, but I also knew that he did it in conjunction with Gil Boelke, and the work was based on the already-submitted Buffalo petition. Just so you will know my position, Paul Hudson is one of my dearest friends, and he is the one who informed me of the petition's formulation, as far back as January of 1969. He spent a few days with my family in California at the time and gave me a complete rundown on what was happening in Canada. (See **Mr. Virgo Himself**, *this issue.)*

Servicing SSB

Re Boos and Hisses (February 73): I am glad to see you print the pros and cons of the issue.

As one who has been a ham for years but due to lack of time, money and energy trying to keep up with a trade and raise a family, I was not able to keep up with the state of the art in ham radio as I would like to have done (namely single sideband).



W4NVK's article in December 73 and WA8ASQ's letter are thought-provoking to say the least and will make the study of this stick in my mind better than anything else could.

I think WA8ASQ was entitled to the $35 charge to fix this man's equipment, since he has

Clarksdale MS

English Spoken, American Understood

In 73s new feature "DX Corner", K2AGZ, said that German, Czech or Russian Amateurs speak such good English, and comments that American Amateurs sometimes speak poor English, and finds this "downright humiliating".

To a Englishman this is a somewhat surprising statement, not that he has not observed this phenomenon, but rather that the British always imagined that the differences between the language spoken in the United Kingdom and that spoken by some Americans was deliberate on the part of the Americans. A deliberate gesture of independence, a deliberate decision to speak differently from the British, and this does not refer to accent, but to the use of words.

This deliberate difference shows in several ways if you listen on the air. There are those who are deliberately so careless, or appear to wish to give the impression of a slovenliness in their speech which makes one feel that they are saying "we aren't going to take the trouble to stick to all the silly rules that an old-fashioned grammar once laid down. We are going to speak just as the words come into our mouths and be modern."

This is particularly noticeable in the use of the adjective where an Englishman would automatically use the adverb. "Your antenna is working real good" whereas the Englishman would say – "Your antenna is working really well". The use of "good" whereas we should use "well" is a typical example.

But another and much more interesting school of thought uses additional words which the British omit. Thus an American "visits with a friend" whereas an Englishman "visits a friend."

To an Englishman the verb "to visit" is a transitive verb which is followed immediately by the object. It can also be an intransitive verb. But why complicate the issue? Since it is transitive we just "visit people" and see no need to add the extra word "with".

If an Englishman visited George yesterday, he would say "I visited George yesterday". The insertion of the word "with" would only be used if he were accompanied by someone else. Thus – "I visited George yesterday". "Were you alone?". "No, I visited him with Mary", meaning that he and Mary visited George yesterday.

Another example is the expression "For free". If an Englishman finds he can get something without paying for it, he says he "got it free". The American finds it necessary to add the word "for" before free and he says "I got it for free"

Originally, one imagines the addition of the word "for" was a joke, intended to lead the listener to expect a price after the word "for". Thus the listener could expect "I got it for five dollars", and he is suddenly surprised to find that no price follows the word "for". But what may have begun as a joke or a method of emphasis has by now become part of the language.

What is perhaps surprising is that the American language frequently adds extra words. Surprising because the Americans pride themselves on a slick and snappy language. There is the occasional short snappy phrase such as "at" at the end of a transmission instead of "over" – one syllable instead of two. But, in general, the American language becomes longer. What to an Englishman is a "Lift" is an "Elevator to an American. What to an Englishman was a "tram", was a "trolley-car" to an American.

Another and, of course, well known phenomenon is the use in America of words and phrases which were used in England several centuries ago but have died out in England. They are still in common usage in America and are then often re-adopted several centuries later again in England. The classic example is, of course, the Englishman says – I've got a cold". The American often says – "I've gotten a cold". "Gotten" was current usage in England in the 17th century, but it has died out now. The American may even say – "I've gotten me a cold", adding the extra word as in "visiting with" or "for free"

Ban the Book

I have been receiving 73 for several years and generally appreciate the articles. I know that you are always interested in reader opinion, so I am sending this belated note to give my reactions to an article you carried last fall. Due to my schedule, I was only able to jot a note to myself to write when I have time.

In the October 1969 issue of 73, on page 34, you have an article written by Robert Manning, K1YSD. I believe this person writes some technical articles quite frequently. This article, "Vidiots That Have Known Me." was quite shocking in its vulgar language and its general low caliber of thought. I feel that it was entirely out of place in your otherwise fine magazine.

I am not the type to hastily drop my subscription, but I would request that you please exercise more care in the selection of manuscripts in the future. I realize that humorous stories liven up a technical magazine, and I appreciate them, but please, let's keep it clean and above the belt. Thanks.

Jim Wagner
Brecksville OH

RM-1429

How about spreading the word about my proposed rulemaking RM-1429 before the FCC which, in essence, asks for authorization to use F4 (FM Facsimile) emission on the 2 meter band. I understand that the proposal is still under consideration by the FCC (at least the FCC hasn't denied it yet). Any and all interested parties should write to the FCC using acceptable FCC form, i.e. 8½ x 11 plain paper, typed double spaced, 1½" left hand margin, 1 original and 14 copies, etc., and offer their comments. In this way, I feel, sufficient interest shown by the amateur population will help stir the Commission to act on the proposal.

Jim Turrin WA8DCE/N0PCF
PO Box 245
New Philadelphia OH

The Buck

Having two days ago jumped from Tech to Advanced I decided it apropos to subscribe to a ham mag, and being familiar with the dynamic duo (Ken and Mike), I bought a copy of 73 (although I was floored by the $1 price). I have found it not only interesting and educational, but the projects are all of the type the "modern" ham would enjoy; what more can one ask for – ICs, FM, apartment dweller antennas, and an RTTY article far surpassing any I have read previously.

Congratulations to Dave Mann and his "Leaky Lines." The article was superb. Among other things, the ARRL has had their comeuppance coming for a long time.

Thus enclosed is a check for $12 for a three-year subscription. I have to get back and finish reading the issue. A very deserving "well done" to you all!

Stephen W. Gundlach WA3DJH
State College PA

I would like to say first of all that I have found 73 mag at the top of the list. But that's not what I'm writing about. I have had my Novice ticket for six months and am planning to get my General soon; and to tell you the truth, I can't wait to get out of the Novice bands. Ham radio is supposed to be the hobby of friendship. Well, not in the Novice bands. On 40 meters you get chewed alive by higher powered rigs of General and Advanced class ops. On 15 meters the chances of being chewed alive are a lot less, but what about those Novices who leech off you. I mean Novice ops that have other rocks but would rather try to get that weak piece of DX from you, rather than move to another rock or stand by.

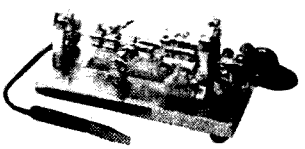
If ham radio is to be the hobby of friendship, why not show it.

Robert S. Damrou WN1LOT
Clinton CT

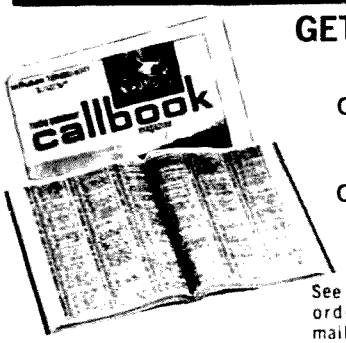
You can tell the guys who have a hard time reading code, like for instance HC2RP. If those fellows spent the same amount of time studying the code as they do thinking up excuses on why we don't need it, they would have it down pat in no time at all. I am sure HC2RP would be copying CW and enjoying it if he took the same time and effort learning the code as he spent composing that almost one page letter. Mr. Romo, I am no genius, but I learned the code almost 50 years ago and I still enjoy pounding brass. Incidentally, I also work SSB and enjoy it also. Cheer up, Edgar, knuckle down and practice and you could be copying CW along with the best.

T.E. Burmeister W8BSS
Cleveland OH

If Jefferson and his peers had spent the same amount of time paying taxes to England as they did thinking up excuses on why we didn't need it, we'd still have a queen.



Thanks for a really fine ham magazine.



Looking through January edition which just arrived here, I find an editor's note referring to Radio Amateur's FM Repeater Handbook." Checking with the biggest local booksellers I found that they will not obtain a copy for me.

DIMENSIONAL GEOGRAPHIC PROJECTIONS

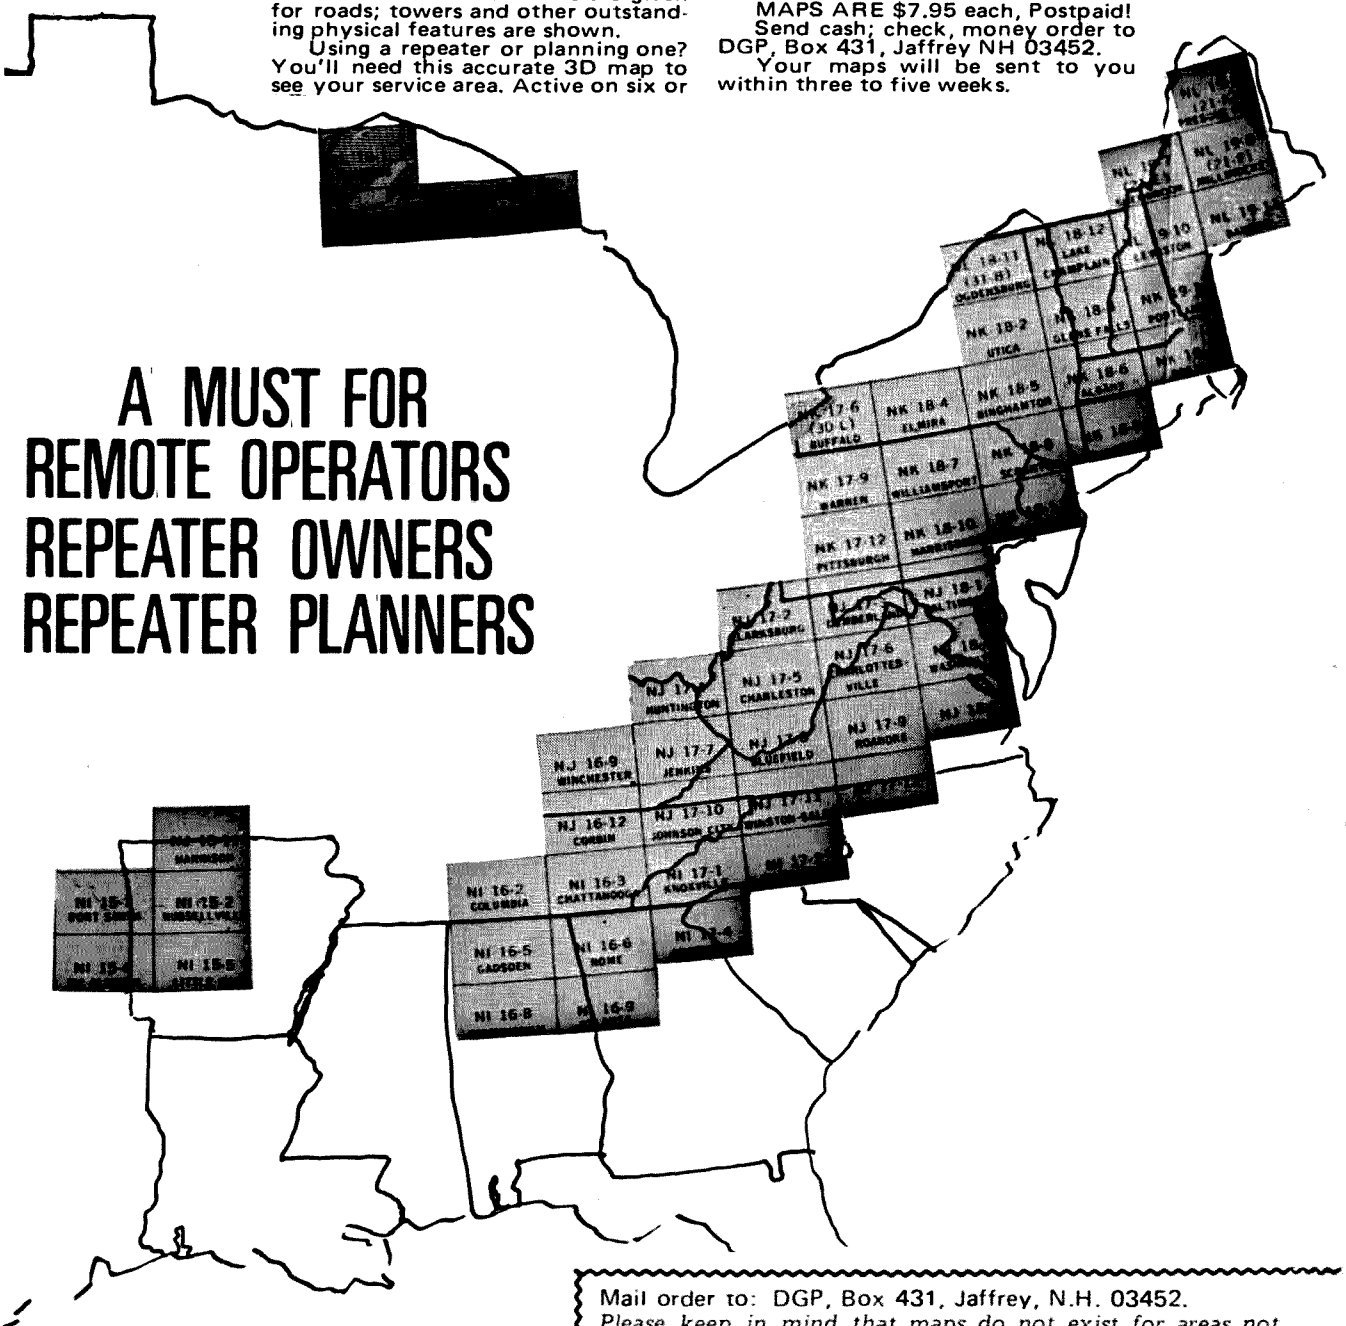
VHF * REPEATERS * FM * SHACK DECORATION *

Here is the last word in maps for the shack. . .three dimensional maps of your area. Maps are available for just about any area where there is mountainous or hilly terrain.

These maps are 18" high by 26" wide and are the most exact three dimensional maps ever made. The detail is incredible. Most maps have even the smallest dirt roads shown as well as altitude markings for every 100 feet and the height of taller mountains. Route numbers are given for roads; towers and other outstanding physical features are shown.

Using a repeater or planning one? You'll need this accurate 3D map to see your service area. Active on six or two meters? Use this map to back your rotating indicator.

These maps are made of permanently molded sturdy plastic, and come to you packaged flat in a large box.



The maps may be cut with a scissors and glued together to form a large mosaic wall mural. You'll need a wall 15 feet high to mount all of California. Each map shows a north-south area of 75 miles and an east-west area of 100 miles.

MAPS ARE $7.95 each, Postpaid!

Send cash; check, money order to DGP, Box 431, Jaffrey NH 03452.

Your maps will be sent to you within three to five weeks.

A MUST FOR REMOTE OPERATORS REPEATER OWNERS REPEATER PLANNERS

Mail order to: DGP, Box 431, Jaffrey, N.H. 03452.
Please keep in mind that maps do not exist for areas not shown – due to flat terrain.

I would appreciate more information regarding the cost and address of the publisher, so that I can send for a copy direct.

For information, here in VK4 there is quite a good deal of activity on 2 meters FM, in keeping with the rest of VK.

For simplex work three national channels are 146.146 MHz, 146.00 MHz, 145.854 MHz.

There are also agreements on frequencies to be allocated to repeaters.

ch 1	146.1 in	145.6 out
2	146.2 in	145.7 out
3	146.3 in	145.8 out
4	146.4 in	145.9 out

The equipment in use is predominantly surplus gear from the commercial mobile bands 148–174 MHz and 72–85 MHz.

John Edwards VK4IE
Queensland Australia

FM Repeater Handbook available from Editors and Engineers, Ltd., New Augusta, Indiana 46268. Price is $6.95 ppd.

Author Talkback

This reply will try to straighten out much of the misconception WA8ASQ read into the Carrier Suppression article on Pg 22, Dec issue, as obvious from his comments in "Boos & Hisses" letter, Pg 12, Feb issue.

First, I find it most interesting that this repairman makes his bucks fixing amateur gear. The fact that he charged a fellow ham 35 bucks to adjust his carrier suppression to a below 40 dB level tells me a lot more about the kind of operation he must run than does his whole letter, which reveals an awful lot. For analogy, the $35 represents at least 10% of the new cost of a transceiver. For analogy, this simple procedure is about as difficult as adjusting the headlight aiming of an auto. Can you visualize a bill for 10% of the car value, $3000 for aiming the headlights? While I can't claim such prodigious credentials as "repairman," I am a registered electronic engineer that did design some of the latest tactical communications systems for Vietnam, so maybe we can talk OK.

Seriously, though, most anyone can tinker a set into tremendous carrier suppression on the bench. My article didn't say this couldn't be done; it said that a very good set will *consistently* have carrier suppression of only about 40 dB. Take one of his tinkered specials into an environmental chamber, vary temperature, voltage, and bang it about some, and see where his carefully nurtured 60 dB ends up. Or, just let the rig cycle in a typical ham shack for a few months; same end result.

The comments about final bias and carrier leakage are a severe case of not reading what is written. Please reread the actual article, with bias filters removed OM.

The $2 mike mentioned works as claimed. I suffer no problems of receiver alignment as I used a rather elaborate audio frequency spectrum analyzer to show the actual spectrum coming out of the transmitter with expensive mikes and others, to find there is no discernible difference, in fact, after passage through a 2 kHz SSB filter. What I said may make a guy that peddles expensive mikes to unwitting SSB set owners unhappy, but facts seldom make merchants happy.

The article makes no claim that 200 PEP is equal to 100 CW, although this interpretation by the critic is not so farfetched as his other comments. My apologies for condensing the writing so much that this lumping occurred to insinuate these two are equal. Actually PEP has no real universally accepted meaning except when using a two-tone test and as a rating on equipment. Even then it means little since the distortion limits on ham gear are never mentioned. Raise the distortion limits you are willing to permit, and you can raise the PEP rating of any rig. However, since Mr. Kirsch is interested in edification, let me proceed. I have a linear that deliberately uses very unregulated voltage on the plates to give a form of audio compression. The absolute maximum the power supply puts out on CW is 900 watts input. However, on voice peaks, it puts out well over 2000 PEP, and this sounds fine because the collapse rate of the input DC voltage is about the same as the rate of compression allowable in successful audio compressors. This of course is a design of my own, which takes advantage of the characteristics of voice waveform compared to sine waves.

I'm sorry that my factual and practical article may steer some Novice hams away from Mr. Kirsch's $4000 repair bench, but that's life. I can understand his position, but that doesn't make me forgive him. Incidentally, a single spectrum analyzer adequate to measure SSB spectrums costs about $5000, so his bench does not awe me. I'll pass, but say that any ham that worries over a carrier suppression that is only 40 dB down is either a Novice or he's playing around, and has little better to occupy his time.

E. Dusina W4NVK

On QRM and Passing Exams

Frequently I cannot agree with some of your "advanced" thinking; but I am only an ordinary person. However, your excellent suggestion to use some brain power and go "where the QRM isn't" seems like excellent common sense. Like any brilliant idea, it makes the rest of us wonder why we didn't think of that instead of just growling at the ills of the ham world.

Your magazine's excellent articles on taking the higher class license, case history and cure for common TVI and audio TVI help ham radio. If only the growlers would put their energies to building themselves up rather than howling at the moon, how much faster we hams would progress in all phases. I was always zero in math and had nothing to do with electronics but when the rules of the game were changed I studied, boned up on the CW, and got the Extra. CW may be a "dead science" but it is a good mental discipline and test which any serious ham can pass. In fact, it is about the only practical "barrier" to the Memory Experts who know nothing about ham radio but memorize the Q and A, pass the nominal CW speed, buy a packaged station, and get on the air as legalized "diddlers." For those who feel the ham rules are unfair, there is always CB or tiddledy winks.

Keep throwing "out the sparks" even tho we may throw water at you!

K.A. Fichthorn W1FK
Southington CT

In the February 1970 issue, page 10-Letters-TVI Case-Daniel G. Willis, SSgt. USAF wrote an inquiring letter about Grid W4GJO's TVI suit. There are without any doubt many hams and others interested in the status of this most interesting case. Your answer was brief and incomplete. Do you know how this case stands at present? Your issue was scanned but no other article was found referring to this case.

The case has been dropped, but Grid is holding the bag for a good many hundreds of dollars due to the lawyers for preparative information to defend him. This kind of a lawsuit could be filed against any of us with the present condition of the laws.

Grid needs or could use the help of all those interested; first, to balance the present account, and second, to build up a condition where others will be protected from some crank.

We heard a pretty complete report by Grid at the Sarasota Amateur Radio Association meeting on January 20th. Grid will accept any contributions from individuals, publications, and manufacturers. The amount received over that necessary to pay the lawyers will be placed in escrow to cover expenses for their future plans.

This much information should be published and any further information can be furnished by Grid himself. His address is The Ham Shack, 1966 Hillview St., Sarasota, Florida 33579.

A. Howard Ettinger WN4NJJ
Sarasota FL

Thanks for keeping us posted. 73 wants to know all the details of all such lawsuits. The more they're publicized, the easier help will be to come by.

Just finished reading the February issue of 73 for the umteenth time and I must say you sure can put a lot of printed material in such a small magazine. I am in the hospital and have all the time to read that I want and I have learned a lot.

I would like to state my thoughts on the incentive licensing. I am not in favor of it at all. There are many operators who are physically handicapped as I am and amateur radio is a grand hobby to be interested in to help one relax. Due to my physical condition I am unable to go and take an examination for a higher class of a license. I don't think it is fair to take so much away from those of us who are unable to get a better license. I have listened on all the bands and there is a clear shot without QRM on those "special people" bands and where us ordinary folk get crowded in together and have a rough time. Dayton OH

Samuel F. Warnock K8NLM

Re: Jan. 1970 Issue

After reading "Fascinating Fundamentals: Volta and His Piles" (ZAP), I am naturally looking forward to your next article which, surely, will be entitled "How to make your own Atomic Bomb – right in your own back-yard." (ZAP!)

I am sure that if your science editor had reviewed the ms before passing it, he would have made two recommendations: (1) Be sure that your friendly gas man sells you a battery mixture and not a jar filled with sulfuric acid and (2) he

would have recommended the purchase of hydrometer (which the friendly gas man also sells).

I think also that your science editor should have inserted the following precautionary note: The author mentions both "a battery-mix" and sulfuric acid in the same breath. He undoubtedly means a diluted solution of distilled water and the acid which can be checked as to its specific gravity with the hydrometer, which should read: 1.84 for a proper mixture. Also: Concentrated sulfuric acid should be mixed with water by pouring the acids *slowly into the water.* Never pour the water into the concentrated acid as a large quantity of heat will be liberated. The acid may thus splatter and be dangerous. Please remember this when you issue the article on the making of the bomb; Some simple precautions must also be taken because the bomb could also splatter and become dangerous.

D. Alexander

Probably the only reason our science editor didn't take care of all these details is because we ain't got no science editor.

Rape of Frequencies

I have always been in line with your thinking, but your latest promulgation (do away with all sub-bands) I consider preposterous! You're the guy that supposedly rebels at the mere mention of being *forced* to do something, and then you come forth with this. I would rather imagine the appliance operators would be real pleased! You speak as though all hams are situated as yourself—with all kinds of ultramodern, very expensive equipment, which perhaps can cope with a chaotic condition. But think of the ordinary ham with ordinary equipment. Where does it leave him, were this to come about? Strikes me you're advocating a wrong course. I never see anything advocated in getting whole segments of unused frequencies occupied. Appears to me that Johnny Q. Ham is an ornery critter, squawking very vociferously only after something drastic happens. I never hear anything above the first hundred kHz on 10 or 20 cw, and the top 3 MHz on 6 are pretty barren. And the rape of 40 meters is pretty disgusting. Back in the 5 meter days I had a rig on approx. 59.8 MHz because everyone seemed to hug 56 MHz. I had no trouble making contacts. How many rigs will be found on, say, 53.8 MHz? CW on 2 way up on the tip is just a joke (another example of brainy planning?). Let's not compound a bad situation.

Iver Paulsen W1OL
Woburn MA

If you look again at 6, you'll find considerable activity above 52 MHz. 52.525, 53.68, and others have become national FM channels.—Ed.

The Toilet Float Revisited

I enjoyed W3KNG's article "The 20 meter DX copper ball antenna" on page 40 of the January 1970 issue.

I have found the answer to his toilet float problem and also, by the way, solved many others at the same time.

The people that copper plate baby shoes can copper plate the new plastic floats. Of course,

when you buy the plastic float you must ask for a low-loss type (perhaps Teflon?). If the 32 ft counterpoise is replaced with a mobile whip with a 40 meter resonator on it, it will still be an electrical 32 ft but much more convenient in size. Finally, if the entire shebang is water-proofed with plastic sandwich wrap, everything can be left in its normal place, which doesn't disable the facilities.

This takes care of people with a General or higher class license, but what about us poor Novices? I'm an 80 meter man myself, I was thinking about having the baby shoe people copper plate the entire toilet but my folks are becoming very down on amateur radio. Perhaps with your greater facilities you could carry the ball (no pun) and develop this idea to its full potential. Maybe you could develop a band-switching version of this antenna.

Clifford Major WN2KDO

Williston Park NJ

Massive write-in campaigns have been flops in the past in every instance that I can remember. About the only event that has brought out the vote, so to speak, was the incentive licensing proposal, and that mass of letters was entirely ignored by the FCC.

There are things that can be done to help get that mass of QRM off 40m, and I have written of them in my past editorials. Since deliberate interference to the offending broadcast stations is illegal, it is difficult to come out strongly in favor of this in an editorial. This might have an effect. A more likely attack on the problem would be through the tourist department. If the American amateurs started writing to the heads of tourism of the governments jamming our 40m phone band we might have a chance of some favorable action. We could then get friends and neighbors to send letters, write about it in the papers, talk about it over the broadcast stations, etc. This could carry a lot of weight. Copies of the news clippings and copies of the letters should be sent to the officials of the airlines serving the countries...or their national airlines, if they come here.

This may sound like a lot, but one single person could organize it, if he decided to take the matter into his own hands.

I am sure that we could come up with a lot more good ideas which would put pressure on the SWBC stations.

Please let me know what you hear from Huntoon. I would love to be pleasantly surprised by a favorable reply from him to your suggestion. I do not expect to be surprised.

... Wayne

SCOOP!

Watch for Linear Systems' all-new SB-35 transceiver, to be unveiled at the Harrison Show this month. Diane Shaw, 73 Advertising Manager, got a "sneak preview" of the transceiver recently when David Bradley gave her a tour of Linear Systems' Watsonville, Calif. facilities.

FCC SAYS NO WORDS ARE NO-NO'S

The FCC questioned CB'er Richard Tallman's qualifications to hold a Technician-class amateur license because of his prior violations of rules pertaining to: (1) hobby-type use of his CB station, (2) failure to identify his station properly, and (3) transmission of "allegedly obscene, indecent, or profane language, words, or meaning." In scheduling a hearing for the case, the constitutional issues raised by the FCC's rule against profanity were noted by Commissioner Nicholas Johnson.

Johnson concurred that a hearing should be held to determine the applicant's qualifications to become a ham, but he emphasized that the "profanity" issue should be dismissed. "I believe a license renewal hearing on the basis of the first two alleged violations is clearly warranted," he said; but then he added, ". . .when we revoke licenses for the *content* of the speech. . .we enter an area of constitutional law which is hedged with important restraints against the power of government to curtail freedom of speech." Because of a recent supreme court decision involving the impact of the First Amendment on broadcasting, Johnson said, the Federal Communications Commission cannot punish—"by fine, license revocation, one-year re-

"Agh! By golly — by golly!"

'vagueness' and 'overbreadth.' See, *e.g., Zwickler v. Koota*, 389 U.S. 241, 249 (1967); *Columbia Broadcasting System (WBBM-TV)*, 18 F.C.C. 2d 124, 143, 150 (1969) (dissenting opinion). It might easily constitute a prohibited 'establishment of religion' as well."

"Webster's Dictionary defines the word, 'indecent,' as 'not proper and fitting; unseemly; improper,' or 'morally offensive; immodest; obscene.' Again, unless 'indecent' is narrowly limited to the technical definition of

Ham Wins Test Case

A Chesapeake, Virginia ordinance against transmitters and towers was defeated in the courts recently by Gay Milius W4NJF, who was acting as attorney for Ted Anthony K4OQB, in a civil case that tested the legality of the regulations.

Tri-State Hamfest

by WA9WCE

The Tri-State Amateur Radio Society is holding its twenty-third annual hamfest on Sunday, July 12, 1970, at the 4-H Rural Youth Center on Highway 41 North, Evansville, IN. Advance registration $1.50; and $2.00 at the door. For details contact Jack Young K9LAU, Box 492, Evansville, IN 47703.

British Carnival Rally

by G3BID

By permission of the United States Third Air Force, the Amateur Radio Mobile Society will be holding a carnival rally on 5 July 1970 at Alconbury, United States Air Force Base in

Cook Bicentenary Award

The Wireless Institute of Australia has a nice certificate available for anyone contacting fifty AX stations during 1970. Send a list of the stations you have contacted in order of call signs by call areas plus the date, time (GMT), band, mode, and report for each contact. Have this list certified by two other licensed amateurs plus a statement to the effect that they have seen the entries in your log. Send your application (no QSL's) to Awards Manager WIA, Box 67, East Melbourne, Vic., 3002, Australia. Add eight IRC's if you would like the certificate by airmail.

Western Illinois Hamfest

The Western Illinois Amateur Radio Club is holding its 10th Annual Hamfest on June 7th, 1970, at the Adams County Fairgrounds located North and

newal or other sanction"–a licensee "for speech which is protected by the First Amendment."

In his in-depth statement (published by the FCC as an appendix to Docket 18804), Commissioner Johnson gave detailed reasoning behind his controversial stand:

"The Commission has promulgated guidelines for forbidden speech in Rule 95.83 (a) (3). The Rule's prohibitions of "obscene, indecent or profane language, words or meaning" are apparently taken from 18 U.S.C. § 1464. Each of the three elements in Rule 95.83 (a) (3) warrants consideration, for I am increasingly of the belief that one or more of them are unconstitutional abridgements of the freedom of speech.

"The concept of 'obscenity' has been defined by the Supreme Court in the famous case, *Memoirs v. Massachusetts*, 383 U.S. 413,419 (1965). The Court has not, however, to my knowledge, ever said that particular *words* are 'obsene' *per se*. On the contrary, the Court has always stressed the *context* in which the words appeared, asking whether the dominant theme of the material 'taken as a whole' appeals 'to a prurient interest in sex.' Individual 'four-letter words,' so-called, may arouse a number of emotions in the listener; but I rather doubt that a 'prurient interest in sex' is one of them. Presumably the hearing examiner in this case will address this question – along with such other constitutionally required questions as whether Mr. Tallman's speech was 'utterly without redeeming social value.' A study of the function of 'four-letter words' in our society, for example, might be useful, or necessary, component of this latter inquiry. 'profane' as 'showing disregard or contempt for sacred things; irreverent.' Any attempt by this Commission to punish for 'contemptuous' or 'irreverent' speech would almost certainly, in my mind, suffer from unconstitutional 'obscenity,' there is little doubt in my mind that its breadth and vagueness make it unconstitutional. In *Interstate Circuit, Inc. v. Dallas*, 390 U.S. 676 (1968), for example, the supreme court cited with approval an earlier case, *Holmby Productions, Inc. v. Vaughn*, 350 U.S. 870 (1954), which declared unconstitutional a statute containing the words, 'cruel, obscene, indecent, or immoral.' And just last year in *Williams v. District of Columbia*, No. 20, 927 (D. C. Cir., June 20, 1969) (en banc), the United States Court of Appeals threw out a statute with wording almost identical to Commission Rule 95.83 (a) (3). The invalidated District of Columbia statute also contained the words, '. . .profane language, or indecent or obscene words.'

"My essential point is that this Commission has designated a license renewal application for hearing pursuant, in part, to Commission rules which appear unconstitutional on their face. I am concerned that the Commission takes this step without attempting to formulate precise standards for permissible speech over the broadcast medium – assuming *any* such standards could withstand constitutional scrutiny. I concur in today's action, however, solely because grounds exist for possible license revocation which are completely independent of the allegations raised under Rule 95.83 (a) (3), and because the Commission will have the opportunity at a later date to review the policy and law in this difficult area."

Slow-Scan Hams Active Worldwide

by WA7LQO

A world-wide slow-scan TV net has been meeting between 1800 and 2000 GMT weekdays. Stations in Alaska, Belgium, Sweden, U.S.S.R., Italy, as well as the U.S. and Canada have been sending pictures.

Huntingdonshire, England.

Any inquiries regarding the rally or regarding reciprocal licensing arrangements should be addressed to:

BCM/ARMS, London, W.C.I.

Application forms for British reciprocal licenses can be obtained from:

Ministry of Posts and
Telecommunications,
Telecommunications and Radio
Regulatory Division
Amateur & Special Licensing Branch
Waterloo Bridge House
Waterloo Road, London, S.E. 1.

The cost is £3 for a fixed license or £1.10 Od. for a Mobile License. Amateurs can apply for both, or either, but a separate mobile license is necessary in Britain for mobile operation.

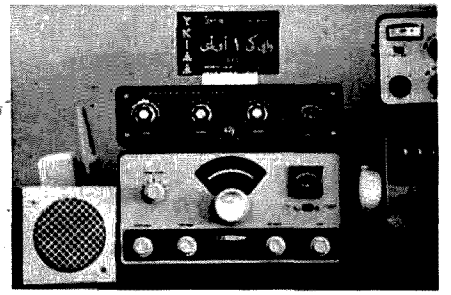
1970 Ham-of-the-Year Award

The Federation of Eastern Massachusetts Amateur Radio Associations is now requesting nominations for the "Ham of the Year" award for 1970. Only amateurs in the first call district are eligible and the ham selected will be the top "good neighbor" among hams – the one who has performed an outstanding public service.

Anyone may nominate a ham for the honor. Winner of the award will be chosen for the ham activity which brings the greatest benefit to an individual or group and for the amount of ingenuity and personal sacrifice displayed in performing the service.

Nominating letters should include the candidate's name, address, call letters and complete description of the service performed. Letters must be sent to the chairman of the FEMARA awards committee, Eli Nannis W1HKG, 37 Lowell St. Malden, Mass. 02148 before September 1, 1970.

The winner will be presented with a plaque and a cash award at the ARRL National Convention, Statler-Hilton Hotel, Boston, Mass. on September 26, 1970.



East of Quincy, Illinois.

Calling frequencies will be 3.910 MHz, 7.258 MHz (Mid-Cars) 146.94 MHz and 146.34 MHz 2 meter FM Repeater.

Swap-shop, prizes, games, lunch, ALL-COVERED FACILITIES. Event will be held rain or shine. Camping facilities are available on the fairgrounds.

For further info contact WA9ARG, Marshall Goins, 2316 Van Buren St., Quincy, Ill. 62301.

SYRIAN MARATHON OPERATION PLANNED

Rasheed YK1AA and Hikman YK1AM are planning a round-the-clock three week operation for October 1970, with extensive friday operations from then on through February 1971. The details of equipment are being worked out with Stu Meyer W2GHK/4 (DXpedition of the Month) and they should be on all bands with good signals. This ambitious operation should take Syria off the rare list for a long time to come. All it takes is one good effort like this to do it.

A copy of the 73 DX Handbook has been sent to Rasheed so he will have information on how to best handle the pileups of stations calling. Using the techniques described in this book he and Hikmat should be able to contact three to five a minute, even when their signals may not be too strong.

FCC Proposal Will Shoot Down Ham Satellites

The proposed Docket 18803 for regulating amateur repeaters has a serious hooker in it. . .a proposal that repeaters not be permitted to repeat other repeaters. If this gets passed, then a set of synchronous satellites for 450 MHz is out the window. This could be the most severely restrictive legislation yet for the future of amateur radio.

The rapid development of FM repeaters plus the amateur satellites means that the time is not far off when we can put a series of three synchronous satellites in orbit which will permit any amateur in the world to contact any other on 450 MHz. Imagine what a change that will make in our hobby! Armchair copy signals without QRM from anywhere in the world. This could be the biggest step ahead for the hobby since its inception. . .if 18803 does not go through as proposed.

Rear back and fight this one out. Send in your comments. . .get your club to comment. . .your friends. . .the fellows on the air. . .leave no stone unturned. Get your congressman to complain about this. . .your senator. . . get Barry Goldwater to help kill this provision. . .maybe even the ARRL.

Penn-Central Hamfest

by W3GPR

The seventh annual Penn-Central Hamfest by the Williamsport and Milton clubs will be held Sunday, June 7, 1970 starting at 12:00 noon at the Union Township Volunteer Fire Grounds on Route 15, Winfield, Penna. Informal, picnic style, snack bar handy or bring your own lunch – come and go as you please. Auction, contests, swapping, free parking, with both indoor and outdoor facilities provided. A $2.00 registration fee may be paid at the gate. XYL and children admitted free. Exhibits welcome. For information contact Al Schramm, 311 E. Mountain Avenue, South Williamsport, Penna. Phone - 717-323-5576.

1970 ARMED FORCES DAY COMMUNICATION TESTS

Each year on the third Saturday in May, the Department of Defense sponsors the observance of Armed Forces Day. As a part of this observance the Departments of the Army, Navy and Air Force annually conduct communication tests designed to demonstrate to the world the close partnership and mutual respect enjoyed between U. S. amateur radio operators and the U. S. military. This year's program will be conducted on Saturday, May 16, 1970, and all licensed radio amateurs are encouraged to participate.

The radio amateur's contributions to communication training, international goodwill, military morale and emergency services are recognized by every echelon of the military services. The Armed Forces Day communication tests are designed to be a tangible demonstration of the firm and long-standing Department of Defense policy to encourage and support amateur radio activity. On this twenty-first observance of Armed Forces Day, all radio amateurs are invited to participate and demonstrate to the world the close partnership and mutual respect that U. S. amateurs and U. S. military enjoy.

Once again this year, several military radio stations will participate in communication tests which include military-to-amateur crossband operations and receiving contests for both CW and RTTY modes of operation.

Special QSL cards confirming crossband communications will be forwarded to those amateurs who establish two-way contact with participating military stations. Certificates will be awarded to those who aptly demonstrate their operating ability and technical skill by receiving a perfect copy of the Secretary-of-Defense-originated CW or RTTY message transmitted during the receiving contest portion of the communication tests.

Military to Amateur Crossband Test

Military radio stations WAR, NSS, NPG and AIR will be on the air from 16/1400 GMT to 17/0245 GMT. During this test of crossband operations, the military stations will transmit on specified military frequencies while amateur stations will transmit in the indicated portions of the amateur bands. Contacts will consist of a brief exchange of locations and signal reports. No traffic handling will be permitted.

CW Receiving Contest

A "CW" receiving contest will be conducted for any person capable of copying International Morse Code at 25 words per minute. The "CW" broadcast will consist of a special Armed Forces Day message from the Secretary of Defense addressed to all radio amateurs and other participants. The schedule for this broadcast is as follows:

STATION	MILITARY FREQUENCY	EMISSION	APPROPRIATE AMATEUR BAND (MHz)

TIME	TRANS. STATION	FREQ (kHz)

News, Reviews, Announcements

IOWA PICNIC

by WØRJZ

The Iowa 75 meter phone net annual picnic will be held on the second Sunday in August – August 9, 1970 – at Anson Park in Marshalltown, Iowa. All amateurs and their families are cordially invited. Each should bring a covered dish and his own service. Festivities will begin around noon. Prizes will be offered and a swap table will be available.

Floridafest

The ST. PETERSBURG AMATEUR RADIO CLUB, INC. will hold its annual Hamfest at Lake Maggiore Park, entrance gate at 9th Street South and 38th Avenue, St. Petersburg, Florida, Sunday May 17. All hams and guests cordially invited. This is an oldfashioned hamfest with picnic lunch, swap table and prizes.

OLD OLDTIMERS GET NEW OFFICERS

Andrew L. Shafer W8TE is the new president of the Old Old Timers' Club, Inc. with William B. Gould K2NP as the new Vice President.

Ray Meyers W6MLZ has been appointed Executive Secretary-Treasurer and Editor of "Spark Gap Times" official magazine for the OOTC.

Directors serving the ten U.S. Call Areas are:

	District
Walter S. Rogers W1DFS	1
William B Gould K2NP	2

RTTY Receiving Contest

A radioteletypewriter receiving contest will be conducted for any individual amateur or station possessing the required equipment. This is a test of the operator's technical skill in aligning and adjusting his equipment, and serves to demonstrate the growing number of amateurs becoming skilled in this method of rapid communications. The "RTTY" broadcast will consist of a special Armed Forces Day message from the Secretary of Defense to all radioteletypewriter enthusiasts. The message will be transmitted at 60 words per minute in accordance with the following schedule:

TIME	TRANS. STATION	FREQ. (kHz)
16 May 1970		
17/0335 GMT	WAR - Army	3347, 6992.5, 14405
16/2335 EDST	NSS - Navy	4012.5, 7380, 13940

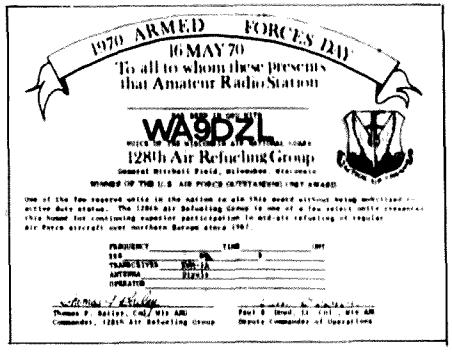
	A6USA - Army Radio San Francisco	6997.5
	A5USA - Army Radio Fort Houston TX	4025



Submission of Competition Entries

Transcriptions should be submitted "as received." No attempt should be made to correct possible transmission errors.

Time, frequency and call sign or the station copied as well as the name, call sign (if any) and address of the individual submitting the entry must be indicated on the page containing the text. Each year a large number of perfect copies are received with insufficient information, thereby precluding the issuance of a certificate.

Completed entries should be submitted to the Armed Forces Day Contest, ATTN: AFOCCOM, Room 3E099, James Forrestal Building, 1000 Independence Ave., Washington, D. C., 20330, and postmarked no later than 31 May 1970.

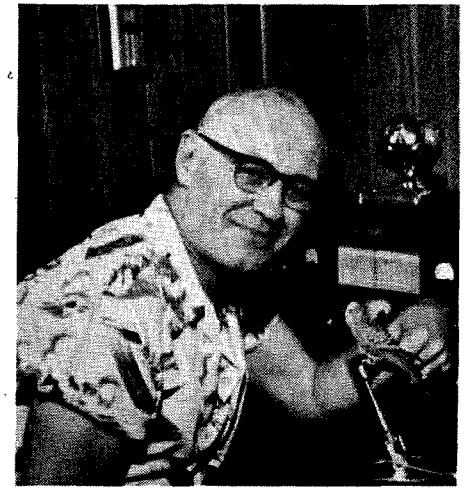
Military Hams to Award Armed Forces Day Certificates



by WA9NVO

On Saturday, May 16, 1970, WA9DZL, amateur station of the 128th Air Refueling Group (TAC), Wisconsin Air National Guard will place radio equipment on the ham bands in conjunction with Armed Forces Day. An attractive commemorative Armed Forces Day certificate will be mailed to all hams who contact WA9DZL on this day. The operating schedule is as follows:

14.297 MHz	1300 GMT – 2100 GMT
7.280 MHz	1300 GMT – 1730 GMT
28.650 MHz	1730 GMT – 2100 GMT

It is anticipated that all states and continents will be contacted. To qualify for a certificate, just make a two-way contact with WA9DZL and send in your QSL card to WA9DZL, 128th Air Refueling Group (TAC), General Mitchell ANG Base, Milwaukee, Wisconsin 53207.

Editorials

DXer's Death is Loss To All Ham Radio

by W. R. Lathrop W4PR

The amateur radio fraternity lost one of its great citizens on March 7, 1970 when E. C. Atkerson died unexpectedly of a heart attack. Ack – hardy, robust, energetic – had his first warning last fall when he was hospitalized from a serious heart attack. He recovered quickly, continued under doctors' orders, dieted, took care of himself, and alowed his active business pace. However, there came a second attack on Saturday and Ack died instantaneously.

Ack loved amateur radio. He began in 1921. He dovoted himself, over the years, not only to enjoying this fascinating hobby but in using his facilities in service to his country as well as the general public. His profound self-taught knowledge of electronics, for example, was voluntarily put to use in the last world war. The country then with a client. Yet, let a child walk in, whose head perhaps didn't reach far above the counter, one who professed an interest in becoming a radio amateur and Ack would "give him the store." Despite the rush of business, he would take time out – sometimes for hours to explain, advise, and lead the youngster toward his goal. More often than not the youngster would walk out with needed equipment even though he did not have the money to pay for the items wanted. He never lost interest in these children, and he continued to help and advise throughout their amateur careers. Ack was particularly generous in donating equipment new and used. He was instrumental in providing most of Alabama's civil defense equipment in the early days. Since Ack never talked about what he did and to whom he sent equipment, there is no telling how much gear he packaged and sent at cost or free of charge to needy hams, missions, and the like.

Ack particularly loved animals of all kinds. Out of hundreds of such stories illustrating his kindness to the animal kingdom, one should suffice which fully illustrates this trait. One day he found a pigeon with a broken wing outside his store. He personally took it to the veterinarian, had it treated, nursed and treated it back to health. He footed the bill and freed the bird on its recovery. He never spoke of what he had done.

Virtually the whole DX fraternity knows and appreciates Ack's interest and help in his efforts in this direction. Few know, however, of the tremendous difficulties, the sweat, the hard work, and the time involved in doing the necessary to receiving permission for Gus, W4BPD, to operate from the various exotic places that he visited. Nor do few know the personal expense, the vexation, the many problems met and solved or of the thousand and one other details carried on by Ack in connection with Gus' travels. It was Ack's idea, thinking of the small Propagation Study Association were available when Don's partner, Chuck Swain, was lost at sea. He did much to keep the search going until hope was finally abandoned.

Then came again a second Gus Browning expedition with all the work and effort which Ack shouldered without hesitation. These three well known expeditions tell part of the whole story. Ack's personal interest, his energy and drive were, however, lent to countless expeditions. Financial help, on Ack's suggestion, sometimes came from the World Radio Propagation Study Association. Ack personally contributed his own money and equipment and help in countless sorts.

Although there is much more, let one more example of Ack's influence and interest suffice. Through a long-time radio communications correspondent and friend, N. Chhwana, a high official of the Bhutan government, Ack arranged to have the king invite Gus to visit that country. As a result of that visit a strong friendship was developed and knowing, through Gus, of the Bhutan's needs of radio equipment, Ack shipped much equipment to the government of Bhutan, much of it at his own expense. Then through personal appeals to many radio friends and appeals through the World Radio Propagation Study Association, Ack collected and shipped a tremendous amount of radio equipment to Bhutan – all donated.

Yes, amateur radio lost a devoted, amazingly helpful citizen when W4-Echo-Charlie-Ida's cheerful voice was silenced! We all owe him much. Truly Ack deserves a top spot in amateur radio's Hall of Fame.

Bermuda Phone/CW

change reports with U.S., Canadian and VP9 stations only. U.S. and Canadian stations may not exchange reports with another U.S. or Canadian station; likewise U.K. stations may not exchange reports with other U.K. stations.

Points

Each contact must be complete and will count three points.

Scoring

The score for U.S., Canadian and U.K. stations will be the number of completed contacts times three points, times the total number of Bermuda Parishes worked on all five bands, i.e. a U.S. or Canadian station having made a total of 500 contacts with U.K. and Bermuda stations and the following Bermuda Parishes: 28 MHz - three Parishes; 21 MHz - six Parishes; 14 MHz - three Parishes; 7 MHz - two Parishes; 3.5 MHz - two Parishes, the score would be 500 contacts times three points = 1,500 points times 16 Parishes = 24,000 points final score. A U.K. station completing 500 contacts with U.S., Canadian and V P 9 stations would score in exactly the same manner.

Equipment

Any number of transmitters and receivers will be allowed and competitors may use the maximum power permitted. However, all stations participating must be single operator only.

Awards

A trophy will be presented to the winner of each mode. A certificate signed by His Excellency The Governor of Bermuda will be sent to the highest scoring station in each call area as follows:

U. S. A. and Canada: W1 through WØ and VE1 through BE7 including VO.

U. K.: G, GD, GM, etc.

Presentations

Round trip air transportation for two plus one week's accommodation at

had need of a tremendous number of technicians to operate the radio gear used during that war. Ack volunteered to teach and to train technicians. He did so during the war period. All along before and after the war he used his facilities wherever possible for traffic handling. On the second Byrd expedition to the Arctic in 1939, Ack established and maintained constant contact with the expedition. Interestingly enough, the expedition was split into two camps some 1800 miles apart. There was an eastern location and a western location and they took radio equipment along to maintain contact between the two camps. Little was known about propagation in the Arctic in those days and much to Byrd's dismay the contact between the two camps was impossible with the equipment on hand. Ack could copy, however, both camps. He therefore linked the two together by maintaining twice-daily contact. He handled all the communications between the two units until suitable radio equipment was sent in. During the period of the Byrd expedition he handled thousands of personal messages from those with Admiral Byrd to their families throughout the United States.

Again in prewar days he established contact with the Kenner–Green scientific expedition to Peru. He was their main contact with the outside world for that expedition deep in the jungles of this South American country. Ack later rendered tremendous service to families throughout the United States when a volcano in Hawaii blew its top causing untold damage and destruction. Ack's station was the principal radio link.

Ack's interest in amateur radio caused him to found Ack Radio shortly after the last world war. Ack was an alert, capable, hard working, imaginative, "tough" businessman, and Ack Radio grew and thrived. He might well have been abrupt and business-like amateur without funds, who insisted on QSLs for everyone regardless of their contribution.

The World Radio Propagation Study Association also was Ack's idea. Not only did this organization act as a recipient of, and a disposal medium for the contributions from thousands of amateurs, but the analysis of Gus' logs and the propagation conditions pertaining to it were studied to provide benefits for amateurs the world over, the governments visited and various commercial interests. These studies were made and distributed.

After Gus' first extended travels, the World Radio Propagation Study Association backed and sent Don Miller on a similar expedition. Ack saw to it that funds from the World Radio

160m DX

by W8ANO

During November 1969, Stewart W1BB came out to the 8th district to see what was making all the racket on 160 meters. Here is what he found: Three 8s very interested in 160 meter DX. I have worked the following 160m DX since Nov: ZS, HR3, PJØ, KP4, VP9, KV4, HR2, ZL1, G3, GW3, DL9, KL7, G2, G8, KS4, VK5, VO1, VK3, KH6.

Contest

by Jim Sayer VP9BY

Bermuda hams have been active participants in the realm of amateur radio since well before the inception of the Radio Society of Bermuda in the late forties. Several of the old single-letter calls are still to be heard. In 1959, in honor of the Bermudas' 350th Anniversary it was decided to hold a contest embracing amateurs in the United States, Canada, and Bermuda. This proved to be such a resounding success that it was continued in 1960 and has been a yearly feature of hamdom since that time.

In 1969, the 10th anniversary of the contest, it was decided to celebrate by having a phone weekend and a CW weekend. This decision was met with equally resounding success and it was agreed to continue the same this year and to invite the U. K. amateurs to participate.

Contest Period

PHONE: 0001 G.M.T. June 20th to 0200 G.M.T. June 21st.

C. W.: 0001 G.M.T. July 18th to 0200 G.M.T. July 19th.

Bands

The following amateur bands will be used: 3.5, 7, 14, 21, and 28 MHz.

Exchanges

Amateurs in the U.S., Canada and the U.K. will transmit a two figure number representing the R S report plus their State, Province or County. CW participants will transmit a three figure number representing the R S T report plus their State, Province or County. V P 9 stations will give R S or R S T reports plus Parish.

U.S. and Canadian stations may exchange reports with U.K. and VP9 stations only. U.K. stations may exchange reports with U.K. and VP9 stations only. The Top of the Town Hotel will be provided to enable the overall winners to attend The Radio Society of Bermuda's Annual Banquet to be held on October 22nd to receive their awards.

Log Instructions

Keep all times in GMT and all contestants to compute their own scores and check logs for duplication to assist the Contest Committee. Print name and Call on each Log. All contestants must sign a statement that the rules and regulations have been observed. Official Log sheets can be had by dropping a card to Contest Committee, Radio Society of Bermuda, P.O. Box 275, Hamilton, Bermuda.

Should there be a tied score, the decision of the Contest Committee will be final. All Logs must be received by the Contest Committee of the Radio Society of Bermuda NOT LATER THAN August 15th, 1970.

The following abbreviations of Parishes will be used on CW.

SANDYS	SAN.
DEVONSHIRE	DEV.
PEMBROKE	PEM.
WARWICK	WAR.
SOUTHAMPTON	SOU.
SMITHS	SMI.
HAMILTON	HAM.
PAGET	PAG.
ST. GEORGE	GEO.

RaRa HAMFEST

The Rochester Amateur Radio Association invites you to the 1970 Western New York Hamfest and VHF Conference. Organizing the Hamfest is an all-year effort by a good many of the members of RaRa, a Rochester ham club. Special tables can be reserved for clubs and groups. Check at the registration desk to see where your group can be seated.

An impressive program is planned for the occasion, and special activities are being scheduled for FM enthusiasts.

Tristate Hamfest

by K9VAT

The Western Illinois Radio Club composed of radio amateurs in the tristate area, is sponsoring a hamfest at the Adams County Fair Grounds, Mendon, Illinois on June 7, 1970. A fine program of an entertainment nature is planned for radio amateurs and their families. Seven-hundred people attended the last hamfest and family picnic.

It has been more or less traditional at these events to give away door prizes as attractions to improve attendance and participation. In the past years the various manufacturers and distributors have been very generous and gracious in donating an assortment of prizes frequently used by radio amateurs.

Certificates...

For the Ham Who Has Everything

RRCC — Real Rag Chewers Club.

This certificate is available to amateurs who furnish a signed statement that they have had a continuous radio contact lasting over six hours with one other amateur station. Continuous means just that. . .no time out for anything. On your application, list starting and ending time and date. Please include $1 to cover the costs of handling and mailing.

WAAS — Worked Almost All States.

This certificate is available to amateurs who furnish QSL cards proving two-way radio contact with 49 states. This will greatly ease the anguish of not being able to get that last state. Please include $1 to cover costs of handling and mailing.

FM MOBILE TRANSCEIVER 450 MHz, 2-Channel trunk mount RCA rig in perfect condition. Fully duplexed and operating as a mobile telephone. Includes transmit crystals for 442.12 and 442.05; receive crystals for 448.82 and 448.85. Crystals are from Sentry and are enclosed in ovens. Complete less control head and cables: $100. Will throw in two 4 dB Com Prod mobile gain antennas. Ken Sessions K6MVH/1, RFD 2, Peterborough NH 03458.

FM MOBILE/PORTABLE TRANSCEIVER 2 meters. Varitronics FDFM2. Perfect for repeaters. Six crystal-controlled channels included: .34—.94, .94—.94, .34—.76, .31—.88, .22—.94, .28—.76. Crystals are International. Includes 12V battery pack, mobile battery cable w/connector. $200. Ken Sessions K6MVH/1, RFD 2, Peterborough NH 03458.

10 FOOT PARABOLIC DISHES—Spun Aluminum. Some in original crates. Frequency range 450 MHz to 8.5 GHz. No feeds available. Feeds available from the manufacturer or can be fabricated. $100. FOB Topeka FM Engineering, 3501 Croco Rd. Topeka KS 66605.

SOMERSET COUNTY HAMFEST The 5th SCARC Annual Hamfest will be held Sunday June 7 at the Casebeer Grove 4 miles north of Somerset, Pa. on US Route 219. Registration starts at noon. Rain or shine — Free tables indoors for swap-shop. Write K3YVS, 719 Division Street, Berlin PA 15530.

ROCHESTER, N.Y. is the location for the 37th Annual Western New York Hamfest and VHF Conference, the weekend of May 16th. Location is Bristol 50 Acres, Rte. 15 just south of Thruway Exit 46. Advance registration and banquet only $6.75. Advance sale closes May 9th. Send check to Western New York Hamfest, Box 1388, Rochester, N.Y. 14603. Activities start Friday night followed by full day of technical programming with outstanding speakers. Special activities include MARS, AREC, and QCWA meetings, YL program, code contests and huge flea market.

AUDIO BANDPASS FILTERS for improved receiving or phone patch. Top grade commercial units made by Stancor and UTC. Sharp cutoff below 300 Hz and above 3000 Hz. 600 Ohms in, 10K out, use them back to back for even better results or impedance match. 20 watts max. Postpaid 2 for $5.00. Charter Electronics Box 88, Gladwin MI 48624.

PRECISION TOROIDS, wound to mil spec on high grade tape cores. 1½ in. dia. not potted. Choice of 250, 500, 850, or 1000 MHy. $1.00 each or 6/$5 postpaid. Charter Electronics, Box 88, Gladwin MI 48624.

CHC — Certificate Haters Club.

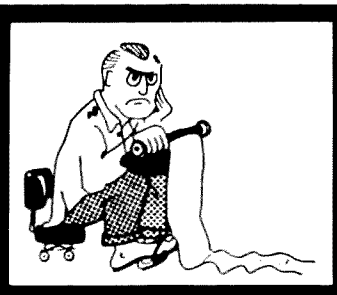
This certificate is available to any amateur who sends a statement saying that he has never enjoyed receiving a certificate, that he hates certificates, and that should he ever by chance receive a certificate in the future he will hate it. Please include $1 to cover handling and mailing costs.

DXDC — DX Decade Club.

One hundred countries is a bit much for Novices, on six meters, on 160 meters, and other esoteric bands, so we have this certificate available for any amateur who furnishes QSLs proving contact with ten countries on the official WTW country list. A dollar bill should cover costs admirably.

WAZP—Worked All Zones Promised

Though interest in the Worked All Zones certificate has dwindled substantially in recent years, every now and then a DXer comes along who wants to try for this award. A statement to the effect that you promise to try and work all 40 zones plus $1 for handling and mailing will bring you this handsome certificate.



Who will be the first amateur to win all five of these handsome awards?

FCC Figures Revisited

EDITORIAL BY WAYNE GREEN

A little over a year ago (February and March 1969) I gave the graphs of the FCC figures on the total number of amateur licensees and the Extra and Advanced class licensees. At that time, with Incentive Licensing just a few months old, it was obvious that there was an increase in the Extra and Advanced class licenses, but we couldn't tell whether it was the start of an upward curve or not. The start was certainly extremely disappointing to anyone that expected some response from the amateurs to the new Incentive Licensing rules.

We have had an awful lot of talk about Incentive Licensing, but what is really happening? What has been the result of the November 1968 and November 1969 band changes as far as upgrading of licenses is concerned. . .and that is supposed to be what this is all about, is it not?

The figures in early 1969 seemed to indicate a massive rejection of the entire principle of Incentive Licensing. Beyond the oldtimers who were grandfathered into the Extra class license, only a handful bothered to go for Extra. . .or at least only a handful made it.

Now that the figures are in through February 1970, what do they show? Has that handful become a mob going for Extra? Were those few stragglers who went for the Advanced class license the forerunners of a horde to come? Is the principle of Incentive Licensing finally being accepted by the rank and file? Has QST managed to get this bitter pill swallowed?

Not exactly.

During February 1970 the FCC issued exactly 73 Extra class licenses. This compares with 278 the previous February. Perhaps this February was somehow different from last February. . .snow or something. . .so let's take an average of five months and see how that compares with a year ago. The average, centered on January 1969 (October through February) is 107 Extra class licenses a month. The year before it was 226, over double!

No wonder the FCC stopped the expansion of the Extra class CW bands!

What about the Advanced class license? Is that where the action is?

Not exactly. In the five months centered on December 1968 an average of 759 Advanced class licenses were issued. In May 1969 the average was down to 329, less than half! It has not picked up substantially since then. The February 1970 figure was under 400.

This should tend to cool off those enthusiasts who have been talking wishfully about the acceptance of Incentive Licensing. It has not been accepted. It *has* been rejected. Let's not let anyone try to fool us about this. Perhaps, now that the vote is in where it really shows, we can prod the FCC into some action to get things back where they were before and set up a more realistic program for encouraging amateurs to progress. The punishment type of incentive as proposed by the ARRL and put into law by the FCC under pressure from ARRL has been the biggest trauma ever to hit our hobby. Psychologically it was doomed to failure from the start. . .punishment as a means for forcing action never succeeds like rewards.

Perhaps it is about time to go back and do what should have been done in the first place. . . consult the amateurs as to what they think should be done. Few amateurs are not in agreement that we need some incentives to urge us to progress. Maybe it is time for the active amateurs to take a hand in their future instead of leaving it to a small unchosen few who have had little active ham experience in years to make the decisions for us from their ivory towers.

What can be done? Well, since you have no representation or lobby in Washington to speak for you, you have to speak for yourself. Get your club to send a petition to the FCC requesting a halt to the Incentive Licensing band allocations . . .get them back where they were in October 1968. Get as many members to sign this petition as you can and send it to the FCC. Be sure to double-space it when it is typed up and don't forget the lousy 14 copies (plus the original). You might make a 15th for me. . .and a 16th for QST. Have the original notarized and send the works to the Secretary of the FCC, Washington, D.C.

Once we get back where we were before this big ARRL production, we can start working on a reasonable incentive system that will reward instead of punish.

The FCC figures put the lie to ARRL's insistence that everything is really all okay and

that most amateurs are accepting Incentive Licensing with good grace and getting their higher grade license. They have tried to maintain the fiction that the opposition to this was by a handful of malcontents and rabblerousers. 73 Extra class licenses in February out of a pool of 130,000 General and Conditional licensees tells the story.

Bright Side. The total number of amateurs, which virtually stopped growing in 1963 (the time of the ARRL Incentive Licensing proposal), has been edging upward again. In 1967 it was down 2%, in 1968 it swung positive to about 0.01%, in 1969 it was up to 0.5% growth, and in 1970 it is up to 2.4%! This is not up to the 10–12% of the pre-1963 growth, but it is certainly encouraging.

FCC Railroading Fee Hike

The FCC announcement of the proposed license fee hikes reached 73 after the April issue had already gone to press. We did manage to quickly insert a little bit about it gleaned from a phone call, but not nearly enough to make it possible for amateurs to be fully informed and comment intelligently on the docket. The closing date for comments was set for April 10th, meaning that by the time we could present the entire docket in the May issue, the official deadline for comments would be long gone. I immediately sent in a petition to extend the closing date and it was quickly denied. For some reason the FCC wants this one to go through with as little opportunity for the amateurs to know what is happening as possible.

Docket 18802 proposes that the amateur radio license fees be increased from $4 to $9. The basic idea is to put the FCC on a cash basis, paying its way with license fees. While I like the idea of a government agency operating in the black, I am about as anxious to help pay for much of the FCC doings as I am to pay for that lovely war in Vietnam.

I can see where it might cost around $4 for the FCC to make up, print, administer, grade, and process a license application and issue the license, but I can't see it costing $9, even considering the inefficiency and waste of the government running the program instead of our ham clubs.

The $9 bite wouldn't be so bad for the older amateurs, fellows who are working and making a living, but it could be a severe blow for the young kids in school and could even prevent many of them from applying for a license. Since most fellows fail the exam the first time through, the bill would run a lot higher than $9. I seem to remember an FCC release which mentioned that it takes 2½ tries to pass the ham license, which would put the ticket around $20 for the first license. One of the last things we need now is a further discouragement for new licensees.

May I propose a compromise? I would be willing to go along with even the $9 fee if the FCC would waive the fee on the first license issued to each amateur. This would permit the youngsters to start out in amateur radio without being heavily penalized and then they would make up for the first free ride later on at renewal time or when they stepped up to a higher license. Presumably they would be in a better financial condition after five years than they would at first.

If you have any thoughts on the matter you had better send them in to the FCC immediately. Though the date for comments on 18802 is now past, I am reliably informed that they will accept comments and put them with the file until the Commission makes its decision. Head your letter as being comments on Docket 18802 and give all of your recommendations as well as your reasons for them. The additional 14 copies will help, if you have a copier handy. Even without, your letter may count. Send it to the FCC, Washington DC 20554.

Do We Need Representation?

Our ignoring of the problems of the ghettos resulted in an escalation of problems, not in their going away. Our ignoring of the growing problems in the schools has had a similar result. I wonder if we are going to continue trying to ignore the problems besetting amateur radio?

The FCC is about to more than double the license fee for us, is on the verge of passing new rules for FM repeaters which could virtually stop the growth of this phase of our hobby and prevent amateur satellite development, and has just slugged us with the most extensive revamping of our bands in the history of amateur radio. When are we going to stand up and say that things have gone far enough?

The blacks decided to do something about their problems. . .and have had success. The students have started making themselves heard . . .with success. You, the amateur who is being done in, have yet to speak out and make yourself heard. How long are you going to take it? Things don't have to go this way and you know it. As long as you continue to play the game with the same marked cards you are going to come out the loser.

We need representation in Washington and we need it right now and we need it badly. We need someone who can protect the interests and rights of radio amateurs. . .someone who can talk turkey with senators and congressmen. . .who can talk with the FCC staff and find out why we are getting dumped on and what can be done to stop it. We need someone who can talk with the military and get them to help us in our battles. They need us and should be reminded of this now and then. We do not have this now. . .we need it.

DX Pileups

An article by G3BID proposed that pileups "attract" and are self-inflating. Obviously he has something there. DXers tuning across the band listen carefully for pileups as a method of finding rare DX. Often they will leap into the pile

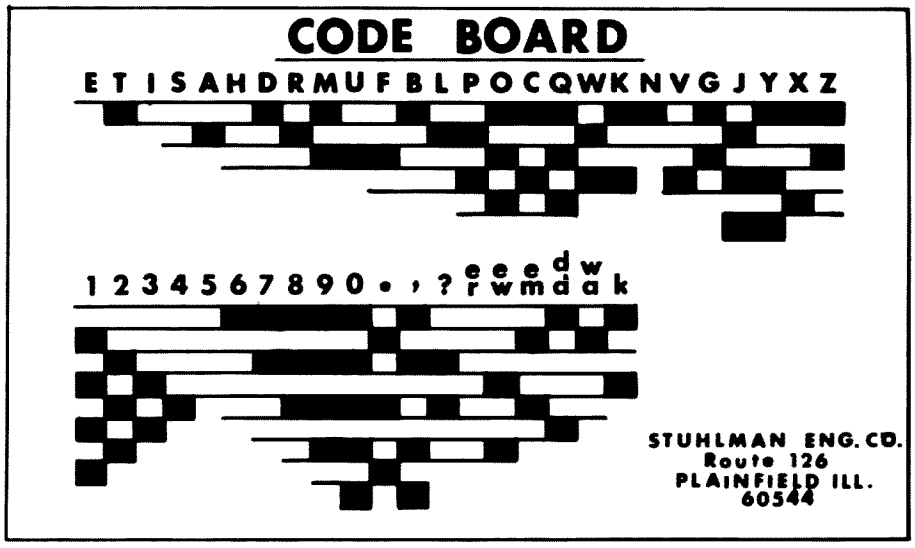
without even knowing who they are calling. This comes out when they make the contact and have to ask in embarrassment for the call of the DX station they are working.

Pileups are caused by poor operating on the part of the DX operator. It is disappointing that so few DX operators avoid the time-consuming and frustrating pileup process. The system for getting the most contacts in the least time, using only one frequency and virtually eliminating pileups, is simple, but when was the last time you heard anyone using it?

Control of the situation is in the hands of the DX operator. Those wishing to contact him will follow his instructions as best they can in order to get that cherished contact. The op must be *absolutely inflexible*. He must set down the rules for getting through to him and then stick to them without exception. If he once breaks his own rules, then he has failed all of those who have been obeying them and they will have every reason to be resentful and even spiteful.



The DX operator should set down his rules and repeat them every few minutes for the newcomers. Rule number one is that all calls must be on the frequency of the DX operator. Rule two is that all calls must be just once, one five-second phonetic spelling of the call of the calling station and no wasting time by giving the call of the DX station. Rule three is that calls will come in the order specified by the DX operator, with no exceptions whatever. It might even bind the cheese better to announce that anyone calling out of order will be placed on a lid list and will be contacted after all others calling are worked.

The problem for the DX op is to get the call letters through the interference. If the calls are spread thin enough this is no problem. Let's say that the band is open to the U. S. and you are the DX op starting a series of contacts. It usually starts slowly with one sharp operator noticing your signal and calling you. When you finish a short contact with him, two or three are calling. You work them faster and by that time there are tail–enders, breakers, and every type of ogre known to the rare DX op. Now is the time to swing into contest style operating. Announce your rules. Then stand by for a specific call area. If the one call results in nothing but a mess, ask for WA1s. This will psychologically prevent W1s and K1s from calling you. If you ask for W1s, you will get all three prefixes. One WA1 should stand out enough to get some of the call. The fast breaks permit you to get this done very quickly. Work K1s next, then W1s. Finish up by asking for any other 1s such as hams from other areas operating "/1"; then you might ask for any DX calls with a 1 in them. Next start in on the 2s. You can check the 2s en masse first, then split them into WB2s, WA2s, K2s, and finally W2s. Don't forget to ask for DX 2s too – they will probably be there. If you forget them you will start hearing them breaking in and botching things up for you.

This system is the fastest one for DXing yet devised. It also is great in that everyone listening to the frequency knows just what is going on and you will find that the dozens or hundreds waiting to get through to you will help you enforce your rules. It only takes one single frequency so you are not hashing up 100 kHz as some inconsiderate DXers do. Also, you are making it easy for the op who does not have a split-frequency system with the callers spread out up and down the band, jamming dozens of contacts for others. Being fast, the calling stations get worked much quicker and few ever have to wait more than 10 or 15 minutes for a contact. The fast activity on the frequency is as much a red flag for the DXers as a pileup, so you never run out of callers while the band is open.

The next time you hear some poor soul struggling with split frequency or tail enders, why not take the time to tell him how to operate. You would do the same for a lid in the U. S., wouldn't you?

The DX op should remember to pass along the QSL information every few minutes and to give his call frequently, phonetically. If things slow down a bit, it doesn't hurt to add a few comments about the country you are visiting for the assembled multitudes.

One other benefit of this super-fast system is that even the low-power stations will be able to get through since you get right down to complete quiet at the end of working each call area. The op will find himself working even mobiles and transistor rigs, making it more fun for all concerned.

European ops can be handled in exactly the same way. Split them up into countries and then, if required, prefixes. With any kind of opening the DLs and SMs will have to be cut very thin to be sorted out.

The split-frequency rubbish was perpetuated all too long because one well known DXer used it. It now appears that he used it because it permitted him to avoid contact with some ops rather than because it was fast. Let's bury this wasteful relic of the past.

The Post Office Mess

Isn't it more than strange that in 1970 we are sending letters just about the same as they were sent in colonial times? In this electronic age it is nonsense for us to have to write on a piece of paper and then send that piece of paper to someone else for them to get the message.

Sure, there are some things that go well on paper. . .legal items such as wills, mortgages, etc., need some permanence, but most of our communications are read and then thrown out. Or, if they are kept, they take up a lot of filing space.

At 73, we get some 200 subscriptions a day by mail. Two hundred envelopes, two hundred letters and two hundred checks. Add to this another fifty or so letters to the editor and other items. Over 80% of the mail in our country is

(continued on page 111)

Ironic as it may seem, I think the biggest stumbling block to the advancement of amateur radio is a lack of communication between the people who make the rules and the people who follow them. Consider that infamous anti-repeater docket, the product of a small group of nervous and suspicious individuals within the FCC.

There are restrictions posed by Docket 18803 that can be explained with no rationalization other than the simple fact that the FCC is worried that amateurs will misuse spectrum, thereby creating more headaches for the Commission by virtue of a possible rash of intra-fraternity complaints of interference and the like. I suspect Docket 18803 is geared first to forestall any such misuse and second to keep the ham radio operation within the realm of the Commission's archaic understanding.

The plain truth is that the FCC has precious little understanding of ham radio. This fact casts no aspersions of ineptness on the good people in Washington, for they certainly mean well. But consider the breadth of their jurisdiction: the billion-dollar broadcasting market, the interstate use of phone lines, the pathetically misused citizens' band, the pay-TV snake barrel, the crowded commercial, industrial, and governmental spectra. Is it any wonder the handful of men in Washington have no real feel for what's doing with the comparatively trouble-free minority group of ham radio?

Paradoxical, yes, but fact: Those well meaning fellows in Washington are painfully ignorant as to the capabilities and limitations of radio as we know it. Attesting to this is the FCC's answer to Wayne Green's recent request for an extension to the deadline for filing comments about the license fee increase. Wayne's reasoning was that more time was needed to disseminate the information. The ham journals needed time to publicize and editorialize; ham groups needed time to plan meetings and have discussions before filing comments. Reasonable? To you and to me, yes – but not to the FCC. The FCC told Wayne that amateurs in particular needed time the least, since hams all have communications capability.

Obviously, the FCC has the idea that if one ham makes an on-the-air announcement, all others will immediately get the word. (And I guess most of us thought that way before we became hams.) The unfortunate thing is, however, that the FCC's official reason was less than no reason at all, and served only to illustrate the communications breakdown between the rule-passers and the rule-followers.

I must admit, albeit reluctantly, that the communications gap is not strictly limited to failings on the part of the Washington bunch. I myself was guilty of misinterpreting when, in a rush to make deadline for the last issue of 73, I published opinions on a docket I hadn't yet seen. I based my comments on a verbal description of Docket 18803, which resulted in my erroneous assumption that remote operation would be illegal (because of the crossband restrictions). Everett Henry called me from FCC headquarters shortly after the magazine came out to set me straight.

I'm confident the FCC doesn't trust us. The people in Washington are wary of saying yes to anything because they're afraid of unleashing another holocaust like CB. As a result, the FCC undoubtedly pores over every petition about repeaters with exasperating caution.

But are we any better? I traveled several hundred miles a few weeks ago to attend one of the many special meetings that are taking place across the country because of Docket 18803. The purpose of the meeting was to examine the FCC proposal, determine what action to take, and make a decision as to how best to act – collectively or individually. *We spent more than three hours discussing such simple trivia as how the proposed rules were worded!* More than one of those amateurs attending the meeting was convinced that the FCC was trying to nail us with subtle wordings. And the result was that we spent our time trying to interpret sentences whose *intent* was pretty plain at a glance. We got nowhere and proved nothing except the fact that we don't trust the FCC, either.

Now, more than ever, I wish I were a sharp attorney. I'd like to present our case intelligently before the FCC, then listen to comments in opposition. I think I'd point out that ham radio needs policing the least of any radio service. Yes, I know the FCC has probably received more complaints about repeaters than any other ham mode – but repeaters have never been legally recognized, so they have always been a subject of controversy. But the real case for repeaters is the case for public interest, convenience, and necessity. More than any other aspect of our hobby, repeaters fill this requirement. Rare is the repeater that has no public service ties. And more and more common is the repeater that is relied upon by local civil defense and other emergency organizations.

I would appeal to the FCC to put 18803 in abeyance, and adopt Docket 1542 as an interim measure, in the same manner as the government of our Canadian neighbors has done. Let us prove our worth. Let us have the opportunity to do what we're licensed for – to serve our purpose to the best interest of the public. There is no clear and immediate need for a tight set of restrictions. Even the FCC can see where the proposed restrictions are detrimental to public interest. What we really need is relaxed restraints so we can develop and grow, and prove even more valuable to the communities in which our repeaters are situated.

. . . K6MVH ■

I find it incomprehensible, listening to the remarks of some hams, otherwise quite placid and mild mannered, when the subject gets around to fellows who wear their hair longer than most of us do. There would appear to be a hidden spring of sadism which wells up to the surface and overflows, and it requires very little stimulus to start this unreasoning thing a-going. But after all, let's face it: long hair does not a "hippie" make.

A certain party I've always liked was heard to expound on this subject. "If I'd had a pair of scissors in my pocket, I'd have given some of those guys a haircut!" Now, of course, this is silly, because a chap's haircut is no index to his political persuasion or anything else. If you doubt that, just turn your memory backward and visualize the late Senator Everett McKinley Dirksen. If ever there was a man with a more disreputable looking mop of kapok on his noggin, I'd like to know who. Yet no one ever faulted old Ev. Leastwise, not about his leonine tonsure. Matter of fact, that unruly hairdo was one of his most notable characteristics, second only to the mellifluous foghorn, that voice with which he spoke the best English extant. . .unique and famous the world over.

On the other hand, in the first days of the Russian Revolution every Bolshevik in good standing shaved his pate clean. I presume that this was proof positive that he had undergone the delousing process regarded as *de rigueur* at that time in that unhappy land. So far as I know (and I couldn't care less) they still need the delousing!

You cannot tell anything about someone's political or social persuasions on the strength of physical appearance. Unfortunately there are some reds who wear the cloth. And there are Cosa Nostra torpedoes who look like bankers and members of the Union League. And I remember a highly successful female film star who made the list of the ten best dressed women several times. Actually, she needed a bath so badly she stank to high heaven!

Now that I reflect upon it, I don't think my friend would really attack anyone with a pair of scissors. As I visualize his all-too-evident head full of pink, shiny skin, drawn as tightly as a snaredrum head, I think it was probably just a case of pure green-eyed envy.

That's all.

Nobody asked me, but . . .

. . . Why do some would-be "control stations" try to set up net-style operations during ordinary, roundtable ragchews? They grandiloquently announce, "John, you give it to Joe. Joe will turn it over to George; George, you pass it to Pete; Pete will give it to Charlie, and Charlie will turn it back over to me." If they're so all-fired anxious to act like traffic cops, why don't they join the police department?

. . . Why is it that when the band is almost devoid of activity, and you're having a nice quiet chat with an old friend, some thoughtless creep starts counting, "One, two, three, four, four, three, two, one. Testing, testing, testing," right on your frequency, or even worse, 500 Hz away? Why is it?

. . . How come some guy in contact with a rare DX station will start to describe his shack, the color of his wallpaper, the ages of all his six kids, his wife's operation, his bursitis, why he switched from vox back to push-to-talk, and who was the King of Albania when he got his first license? And how come this always happens when there are 479 other guys trying to get a contact, especially when the signals are starting to fade into the rising noise level. How come?

New Math

As a public service, and to uphold the dignity of us fuddy-duddies of the older, more benighted generation, I'd like to say a few words about the so-called "new math" that some of the kids are bringing home from school these days. It is disconcerting, doubtless, to hear seven- and eight-year-old tykes uttering mystifying and formidable terms such as "sets, subsets, commutative and associative properties" and the like. In our day, and I blush to admit it, plain old plus and minus were obstacles enough, and I distinctly recall that it took me weeks to learn my multiplication tables.

The essential thing about the new math is that it seeks to be precise, and also avoids the use of misleading inaccuracies of the past. I remember being told, "You can't subtract 9 from 7," for example, and then making the discovery that I could indeed subtract, obtaining minus 2 as the answer. Nowadays kids are taught the essential structure of the subject. . .the why, rather than the how. . .through plane geometry, algebra, number lines, binary arithmetic and sets. They

are also being introduced to analytic geometry, probability, and Boolean algebra. . .all of which were previously restricted to college level courses.

The new teaching, called the discovery method, is worlds removed from the old teaching by rote. By means of a sort of Socratic question-posing technique, children are steered into investigating for themselves the world of numbers. The premise is that what is absorbing and intellectually intriguing is fun, and consequently learned more quickly and more lastingly.

Many parents, unwilling to relinquish the old methods which they learned in school, are finding it difficult to catch on to the new math. Because one of the most important roles of father and mother continues, in spite of changes in attitudes, to be the preservation of a sense of respect for elders in their offspring, this is getting to be a problem. The kids cannot seem to generate much respect for elders who cannot seem to grasp intellectual concepts which they themselves find logical and understandable.

There is an interesting little book, published by the American Book Company, entitled "What About This Modern Mathematics Business?" (A Handbook for Parents.) This book, simply written, explains in clear terms the material which is covered in these new school programs. I recommend it to you earnestly if you are puzzled about this subject.

After all, what are you going to tell your youngster when he asks, "Gee, Dad, will you help me make a Mobius Strip to take to class tomorrow," or, "Say, Mom, what's the difference between the decimal, duodecimal, and binary numeration systems?"

Atrophy

I write a semiweekly column for a suburban newspaper in the area where I live. In casting about for subject matter (I am not restricted in any way), it struck me that I might discuss ham radio. In my column I pointed out that this would be a splendid opportunity for channeling the energies of youngsters in a meaningful and constructive way. I pointed out that there were no acid-heads or glue sniffers. . .no hubcap thieves or child molesters. . .and probably very few radicals or revolutionaries in ham radio.

I also pointed out that apart from the enjoyable aspects of the hobby and the opportunities to perform public services in many ways, participation could also unlock the doors to very rewarding careers in electronics. I closed the column by inviting inquiries, and stated that I would refer all such to regional and local amateur radio clubs, so that the matter of license and equipment could be dealt with.

As a result of the appearance of this column I received several dozen replies. There appeared to be an enthusiastic body of area residents, most interested in becoming involved. This included many adult persons in addition to young people. In three instances the queries involved entire families, both parents and children. This large response was extremely gratifying, and I was sure that in a short period there would be some new amateurs in this area, a most desirable development from every standpoint.

I am chagrined to have to report that I was not able to find too much club activity here. The nearest club to me has been *hors de combat* for the past two or three years. There do not appear to be any truly active radio clubs anywhere in the immediate vicinity, outside of some which are specifically slanted toward individual ham activities such as DX or VHF. Consequently, I have had to combine my own personal efforts with those of some ham friends, in order to get these folks oriented, trained, licensed, and equipped. I have not been able to find a single active radio club functioning here. This is a sorry state of affairs, particularly since there was a great deal of club activity hereabouts in prior years.

The high schools, a natural place for the formation and growth of such clubs, are almost totally devoid of any interest in the matter. One of the main reasons for this is the failure of school boards to provide any funds for this type of activity, and, since the budgets do not call for any expenditures in this area, there are few teacher-hams who could be expected to stand the cost personally, much as they would like to do so. It is unfortunate that while there are always enough funds to purchase footballs, twirling batons and hockey pucks, somehow the schools do not seem able to buy the most inexpensive pieces of used radio gear, so that radio clubs can be activated where they might do some good.

I should like to urge all the readers of Leaky Lines who live in communities where a similar situation exists to instigate programs of their own, in order to awaken interest in amateur radio among area residents. Where the school boards appear to be unenthusiastic in their response to the idea, public demand for such programs may possibly inspire a change in direction. I am confident that there is not a science department in a single school which does not include a teacher who would be willing to assume the trusteeship or leadership of a ham radio club. Offer your services and make yourself available to such people so that your neighborhood school may become a spawning ground for future hams. If we address our energies to such projects there is no doubt that many clubs can be activated.

We all owe a debt to this hobby we love so well. I suggest that one of the most concrete ways in which we can repay it is to see that our enthusiasm is passed along to the youth. If we can institute and maintain a viable, ongoing process of ham recruitment, we will not only be supplying our hobby with a vital flow of new blood, but we will be contributing toward our nation's health by helping to provide constructive, positive and meaningful channels of activity for our youngsters. What could be more important than that?

. . . K2AGZ ■

SPECIAL REPORT

73 Comments on FCC's Proposed Repeater Rules

Many of us by now have had the opportunity to study Docket 18803 carefully. For the benefit of those who have not, I think it is safe to say that this proposal is the most important since incentive licensing, and more devastating to the future of VHF amateur radio than any rule change bid in our history. For repeaters, the proposal changes are stiflingly restrictive and growth-stopping. For remote operation, the proposed rules are disastrous. With these rules, there can be no satellite translators, no mobile remote control operation, no city-to-city links, no cross-country systems. Docket 18803 spells instant death for remote operation as we know it, and imposes complex repeater hardships – and this is no exaggeration. Every radio amateur – VHF'er or low-band operator, repeater owner or not, remote devotee or CW enthusiast – owes it to ham radio to do everything in his power to stop this proposal from getting passed. To do this, here is what *you must* do: Read the FCC-proposed rule changes reprinted here, then write your comments. Send the original and 14 copies of your comments to the FCC in Washington, D.C. *before May 15.* This is absolutely essential. You *must send all 15 copies before May 15.*

The FCC Proposal (Docket 18803 Appendix) is printed in italics below. The comments of the 73 editorial staff are incorporated in close-spaced bold-face type. Your comments may or may not coincide with those of 73. At any rate, you have the chance to see what we think of each item in the proposed rule changes. Make your own comments independently if you like; or, if you feel as we do, tear our comments out, sign it, then make 14 copies and send the whole works to Washington.

If you're involved in a repeater that has public service ties, get affidavits and supporting documentation from your local government authorities. Remember – they, too, have the right to make comments, since their operations are directly affected by the proposed changes, and they do represent the public, whose interest is supposed to be served by amateur radio.

DOCKET 18803 APPENDIX
RULE CHANGE RECOMMENDATIONS OF FCC
(with editorial comments in bold type)

1. In § 97.3, a new paragraph (i) is added to read as follows:

§ 97.3 Definitions

(i) Amateur Repeater Station. An amateur station at a specified fixed location used to automatically retransmit signals of other amateur stations.

2. Section 97.41 is amended by adding a new paragraph (b) as set forth below, and redesignating former paragraphs (b) and (c) as (c) and (d).

§ 97.41 Application for station license.

(b) Each application for a remotely controlled station shall be filed on FCC Form 610 or FCC Form 610-B, as appropriate, and must include a supplementary statement giving the address of the remote control point and indicating whether control will be by wire or radio. If remote control is by radio, complete information must be furnished showing how the transmitter is controlled and what means will be used to prevent unauthorized operation of the transmitter. Data on control frequencies, the function of all relays, timing devices used for control, directional transmitting and receiving antennas in the control system, and other pertinent details must be included.

3. A new § 97.42 is added to read as follows:

§ 97.42 Station location.

Every station must have a fixed transmitter location. Only one fixed transmitter location, which will be designated on the station license, will be authorized unless the station is authorized to be operated by remote control.

4. Present § 97.43 is deleted and new § 97.43 is added to read as follows:

Amateur Remote Stations

§ 97.43 Remote Control of an Amateur Station.

(a) Remote control of an amateur station other than an Amateur Repeater Station from a point or points specified on the station license may be authorized provided:

(1) The remote transmitter is so installed and protected that it is inaccessible to unauthorized persons.

(2) That in addition to complying with § 97.85, a photocopy of the Amateur Station license is posted in a conspicuous place at the remote transmitter location.

(3) The emissions of the transmitter are continuously monitored at the control point.

(4) The radiation from the transmitter can be immediately suspended from the control point when there is any deviation from the terms of the station license or the requirements of this part.

(5) The station is so designed and installed that the transmitter can be activated only from the authorized fixed control point.

Such exclusive activation restricts the operation of a remotely controlled station to the detriment of the public interest, convenience, and necessity. No mobiles, for example, would be allowed to access the remote station, which is at present perhaps the most valuable type of installation for public service applications, would be restricted in such a manner that it would be virtually worthless for all uses except the relaying of signals to and from the control operator's base.

One life—at least—was saved already because of an amateur's ability to access his remote transmitter and phone patch from his car. On a stretch of freeway near Los Angeles, a motorcycle officer had a heart attack and spilled. Motorists stopped but no one could help. Don Milbury W6YAN didn't even stop. He accessed his remote autopatch as he passed the scene, and called an ambulance and the local authorities. The policeman might have died without the prompt medical aid that came as a direct result of Don's call. Amateur radio paid its way that day, and no one could say that Don Milbury's brand of radio is not in the best public interest. If this part of the FCC proposal gets through, operation of a remote station from a car will not be legal.

On another occasion, two amateurs in Pomona, California saw a hit-and-run accident, and telephoned the police from their car using the remote control facilities of K6MVH. The two hams followed the suspect car while they kept up a running conversation with the police dispatcher, who radioed update location data to patrol vehicles in the vicinity. Within minutes, the suspect vehicle was intercepted. The local police were impressed with the hams' communications capability. It is doubtful that this local government considers amateur radio to be a TVI-generating nuisance, as so many others do.

As a suggested alternative rule change for the above-proposed item, how about this:

(5) The station is so designed and installed that master control can always be effected from the fixed control point, and access from the fixed control point shall at all times be capable of overriding all other input signals.

This suggested alternative proposal leaves the door open to operate and control a remote station from a hand-held, portable, or mobile unit, as long as an authorized monitor has the capability of exercising master control from the fixed station.

(6) That if remote control is by radio, the control link is direct, without intermediate relay.

Here, again, is a rule portion that does not appear to be in the public interest. *Master* control of the remote transmitter, of course, *should* be "direct" without intermediary relay. But there should be no rule against indirect control as long as the direct control is maintained from the fixed site. Many remotely controlled stations are situated in such a manner that "direct" control from a low-power station is impossible because of distances, terrain, etc. To circumvent the problems, an intermediary station is set up so that user stations can transmit signals that can be relayed to the remote transmitter. Back-to-back repeater stations are examples of indirect control of a remote facility; they allow installation of phone patches even when there are no phone facilities at the basic remote location. They allow range extension when the users live out of the area where most of the FM action is taking place. In addition, they offer the only means whereby users of one remotely

controlled facility may access and command another such station, situated perhaps many miles from the first site.

In California, New England, and Nevada, for example, experiments have been performed and systems are currently being built that allows repeater groups to access the repeater facilities of other repeater groups by mutual consent. The UHF control facilities for the WB6SLR remote station in California could be used to interrogate the control system for the K7TDQ remote station in Las Vegas. If K7TDQ is willing to allow his repeater to be an input/output terminal, he could electrically command his system to respond to the control signals of the WB6SLR machine in California. The result is a Los Angeles to Las Vegas repeater system interconnected by a controllable 450 MHz link.

Similar cooperative efforts have taken place along the eastern seaboard when Gordon Pugh K2GHR exercised control of several repeaters in New England and Canada from his own remotely controlled station.

Repeater expansion along the lines of metropolitan interconnections – currently being planned between northern and southern cities of California, between Tulsa and Wichita, San Diego and Phoenix, Los Angeles and Las Vegas, and perhaps 50 other places in the country – cannot take place without allowing "indirect" control of a remotely situated station.

(7) That if remote control is by radio, the control transmitters operate on frequencies within a band above 220 Mc/s.

(8) That if remote control is by radio, a timer is provided to automatically limit transmission to a period of three minutes in the event of failure of the radio control link, capture of the control receiver by an undesired signal, or other technical malfunction.

Amateur Repeater Stations

(b)Remote control of an Amateur Repeater Station may be authorized provided:

(1) The installation and operation of the station complies with paragraph (a) of this section.

(2) The station is provided with an automatic timer to limit a single uninterrupted transmission to a period of not more than three minutes. This circuit may be so designed that it will automatically reset but will not permit use of the transmitter until receipt of a properly coded signal.

The last sentence in this segment should be replaced with: "This circuit may be so designed that it will be automatically reset but will not permit reactivation of the repeater until receipt of a properly coded signal." The wording differences between this and that proposed by the FCC are quite subtle, but the reason will be clear when the comments to (4) below are understood.

(3) The station is so designed and installed that overriding control of the station is maintained from an authorized remote control point.

(4) The station is so designed and installed that the transmitter can be used only upon receipt of a coded tone signal after the transmitter has been activated from the control point.

There are two major types of coded repeater control in very common use, both of which offer the protection from inadvertent interference that is the purpose of such control methods. The first type of control is "tone burst entry," where a coded tone is required of each repeater user at every transmission in order for his signals to be repeated. The second type, single-tone activation, is commonly known

as "whistle-on," and allows the repeater to be activated for uncoded carrier operation when the user whistles on the input frequency. In the whistle-on system, the repeater continues to operate on a carrier-operated basis as long as the repeater is in constant use. When a short time goes by with no input signals, the repeater automatically deactivates, and must be "whistled on" before it can be again activated. The rule as proposed by the FCC does not provide for this very functional form of subcontrol, and places an undue burden on all repeater operators to the effect that ALL users must equip their units with tone generators. The intent of the rule can be satisfied without the necessity for all operators installing tone-burst equipment if the rule in question were to be modified as follows:

> The station is so designed and installed that the repeater can be used only upon receipt of a coded tone signal after the transmitter has been activated from the control point; or, in the case of a whistle-on tone system, the repeater can be energized for carier operation provided that a means is incorporated for automatically deactivating the repeater within 3 minutes after the last signal is received. Reactivation after this period can be achieved with a tone from the repeater input frequency only if the repeater has been properly activated from the control point.

(5) The station is so designed and installed that the transmitter will be silenced within five seconds after cessation of the output of its associated receiver.

5. In § 97.61, the introductory text of paragraph (a) is amended, and a new paragraph (c) is added to read as follows:

§ 97.61 Authorized frequencies and types of emissions.

(a) Following are the frequency bands and associated emissions available to amateur stations, other than Amateur Repeater Stations, subject to the limitations stated in paragraph (b) of this section and § 97.65. Frequency bands available to Amateur Repeater Stations are shown in paragraph (c) of this section.

(c) Amateur Repeater Stations must receive and transmit in the same frequency band. Simultaneous transmission in two or more frequency bands is not permitted. The following frequency bands and the emissions authorized in those bands in paragraph (a) of this section are available for Amateur Repeater Stations:

52.50 - 52.70 53.00 - 53.20

Input (Receiving) Mc/s	*Output (Transmitting) Mc/s*
52.50 - 52.70	*53.00 - 53.20*
146.30 - 146.60	*146.90 - 147.20*
223.10 - 223.30	*224.10 - 224.30*
447.70 - 448.90	*449.10 - 449.30*

Any amateur frequency above 1215 Mc/s

The intent of this part of the proposal is to lessen the congestion caused by multiple transmissions of repeaters and to minimize the interference caused by crossband operation, where monitoring of the output before transmission is difficult and impracticable. The outlawing of 6-to-2-meter systems seems reasonable, because both bands are active, often crowded, and are in general use by amateurs using a variety of modes.

But who could deny the attributes of a crossband system between 2 meters and 220 MHz, or between 6 or 2 meters and any of the UHF bands, or between one UHF band and another? Is this not the next logical step in amateur repeaters? And is this not the only practicable method by which amateur orbiting satellite translators and repeaters can evolve?

In the interest of furthering the development and natural growth of amateur radio, there should be no restrictions between crossbanding on these higher frequencies, where the bulk of the activity is already provided by the individuals who inhabit the spectrum for the sole purpose of exploring and exploiting the capabilities of advanced communication forms.

The frequency restrictions of the above subband allocations are also unduly restrictive. Not only would these allocations render a large number of existing repeaters illegal, but they pose problems to the repeater users that are only questionably solvable within the existing state of the art (such as the narrow spread in the 450 MHz region).

There are obvious advantages to restricting repeaters to specific portions of the spectrum, and virtually every VHF operator knows this; for this reason, amateur 2 meter FM operators — including repeater owners and users — have unanimously agreed to populate only frequencies above 146.04 MHz, and then only those frequencies that are spaced at multiples of 30 kHz from one another. In highly congested areas where there is an abundance of FM activity, operators have made unwritten agreements to reduce deviation levels to ±5 kHz at least on alternate channels, and in many cases they have reduced deviation to narrowband standards on all FM channels. Since channelized operation is universally accepted in the United States (and Canada), there would seem little need to establish discrete band portions for transmitting and receiving. Rather, it would seem in the best public interest as well as in the interest of amateur radio, to allow FM repeaters to be established on existing channels, depending on the activity, operating conditions, and individual requirements of the areas where the repeaters are to be used. In some cases, the repeater input should be higher in frequency than the output; in others, the reverse would be more locally suitable. And in some instances, as in separated sites, the transmitting and receiving portions of the repeater could best be placed on the same frequency (as has been done successfully in several installations).

6. Section 97.67 is revised to read as follows:

§ 97.67 Maximum authorized transmitter power.

(a) Transmitter power is the d.c. power input to the final r.f. amplifier. If the final amplifier is of the r.f. grounded-grid of r.f. grounded-base type, the transmitter power also shall include the d.c. power input to the stage which immediately precedes the final r.f. amplifier.

(b) Except as limited by §97.61 (b) transmitter power shall not exceed:

(1) 600 watts for transmitters used at Amateur Repeater Stations.

Since the difference between 600W and the 900W maximum legal limit of remotely operated transmitters represents but a barely noticeable amount (less than 2 dB), little is to be gained by this restriction. An amateur repeater should be allowed to operate with the same power restrictions faced by other amateur stations.

(2) Two kilowatts for single sideband radiotelephone transmitters and other amplitude modulated radiotelephone transmitters using reduced, suppressed, or controller carrier when measured during maximum peaks of modulation;

(3) One kilowatt for all transmitters other than those covered by subparagraphs (1) and (2) of this paragraph.

(c) Equipment capable of operation with transmitter power in excess of 90% of any applicable power limitation shall have installed a means for accurately measuring transmitter power.

7. Section 97.79 is revised to read as follows:

§ 97.79 Operator Requirements.

(a) An amateur station may be operated only by a person holding a valid amateur operator license issued by the Federal Communications Commission and only in the manner and to the extent provided by the class of license held by the operator or the station licensee, including the trustee of a club station, whichever is the lesser.

(b) The licensed operator required by paragraph (a) of this section must be on duty at the transmitter location or at an authorized control point.

(c) An amateur station licensed as a military recreational station may be operated only in the manner and to the extent provided by the class of amateur license held by the person operating the station.

(d) When an amateur station is used for telephony or radioprinter transmissions, any person may transmit by voice or teleprinter, provided a licensed amateur operator is present at the operating position, continuously monitoring the transmissions and maintaining supervisory control of the station, including turning the carrier on and off for each transmission and signing the station off after communication with each station has been completed.

8. In § 97.87, new paragraphs (e) through (h) are added to read as follows:

§ 97.87 Station identification.

(e) In lieu of the requirements of paragraph (a) of this section, an Amateur Repeater Station may be automatically identified by radiotelegraphy at intervals not to exceed three minutes by keying on audio tone superimposed on the voice transmissions. The code speed shall not exceed 20 words per minute, and the modulation level shall be sufficient to be readable through the voice transmissions.

This should be modified to permit automatic identification by telegraphy or recorded voice.

(f) A station licensed to an individual may be identified by its assigned call only when operated by or under the immediate supervision of the station licensee. If the station licensee, who is the owner of the equipment, is not present, the operator must identify his transmissions by using his own call sign with the appropriate portable indicator.

Should also state: An Amateur Repeater Station will be identified only by its designated call regardless of which authorized control licensee is monitoring from an authorized control point.

(g) A club station may be identified by its assigned call only when operated under the supervision of the trustee or an authorized club member.

(h) A military recreation station may be identified by its assigned call only when operated by a member of the Armed Forces of the United States who holds a valid amateur operator license.

9. Section 97.89 is amended to read as follows:

§ 97.89 Points of communication.

(a) Amateur stations may communicate with:

(1) Other amateur stations.

(2) In emergencies or for test purposes, and on a temporary basis, with stations in other services licensed by the Commission and with United States government stations.

(3) Any station, other than an amateur station, which has been authorized to communicate with amateur stations.

(b) Notwithstanding the provisions of paragraph (a) of this section, an Amateur Repeater Station shall not repeat the transmissions of another Amateur Repeater Station.

It is absolutely essential to the growth and technological development of UHF and VHF amateur radio that such restrictions are not imposed. Dual repeaters are invaluable for some applications, such as public service functions outside the area normally served by a repeater.

As an example, the Wichita repeater is heavily depended on by the local government to provide early warning for maximum evacuation effectiveness. Like any other repeater group, the Wichita repeater users have mobile units and hand-held transceivers, which are used in conjunction with the repeater to provide an effective communications system. But what happens when the alert is out of the area of immediate coverage of the repeater? With the FCC restriction of no multiple repeaters, civil defense usefulness suffers, because the mobiles and hand-held units of the group are worthless without the repeater – the heart of the communications system.

On the other hand, if multiple repeaters were not illegal, the repeater crew could take a portable UHF repeater to the scene to act as an intermediary system, extending the range of all low-power units so that the immovable repeater in Wichita could still be used as if the disaster point were actually in Wichita. The intermediary repeater could be no more than a temporary setup designed to operate from emergency power or from the power source of an automobile. This is how such a system works:

Hand-held units transmit on 146.34 MHz and receive on 146.94 MHz, frequencies compatible with the permanent repeater. The intermediary repeater receives on 146.34 and retransmits on the UHF control frequency for the permanent repeater. The control receiver at the permanent site relays the UHF signal to 146.94 and to another frequency in the UHF range. The intermediary repeater accepts the UHF signal and retransmits to 146.94, thereby allowing all low-power user stations to communicate through the permanent repeater by virtue of the dual relay.

Interlinking of repeaters is a vital step in VHF progress, and is one of the most attractive features we have to offer municipalities when we try to show them our communications potential. Using a multiple repeater system, it is now within the state of the art to set up a system of links so that user stations in one city could actually select, via a special access link, repeater interconnections in other cities. With the advent of communications satellites, UHF dial-a-city could become a very common practice – and it could be designed so as to be completely compatible with existing systems on a noninterference basis.

The proposed rule stated in (b) above should be reworded as follows:

Notwithstanding the provisions of paragraph (a) of this section, an Amateur Repeater Station shall not repeat the transmissions of another Amateur Repeater Station *except by mutual consent of the responsible principals of all repeaters to be affected by such a multiple relay.*

10. Section 97.103 is revised to read as follows:

§ 97.103 Station log.

(a) Each licensee of a station other than an Amateur Repeater Station shall keep a log of station operation which shall include the following:

(1) Except when operating mobile, the date and time of each transmission or the beginning and end of a series of transmissions.

(2) When operating mobile, the date and time station operation commences and ends.

(3) Call sign of the station called.

(4) If the transmissions are made through a repeater station, the call sign of the repeater.

(5) The signature of each licensed operator who operates the transmitter from the transmitter location or control point and the date and time of such operation.

(6) The name of any person other than the operator who directly or by recording transmits by voice or transmits by radio teleprinter.

(7) The input power to the transmitter.

(8) The frequency band or subband used.

(9) The type of emission used.

(10) The station location.

(11) If record messages are handled, a copy of each message sent and received shall be entered in the station log or retained on file for at least one year.

(b) The licensee of an Amateur Repeater Station shall keep a log of operation which shall include the following:

(1) The date and time station operation commences and ends.

To avoid misunderstanding, this should state ". . .the date and time repeater is placed in service and is accessible by user stations who comply with access requirements."

(2) The entries specified in subparagraphs (5), (7), (8), (9), and (10) of paragraph (a) of this section.

(3) A record of all installation, service, or maintenance work performed which may affect the proper operation of the station.

(4) The entry required by subparagraph (3) of this paragraph shall be made, signed, and dated by the licensed amateur operator who supervised or performed the work.

(c) The entries required by subparagraphs (5), (7), (8), (9), and (10) of paragraph (a) of this section need only be entered once until there is a change in the required entry.

11. In § 97.193, the introductory text of paragraph (a) is amended, and a new paragraph (e) is added to read as follows:

§ 97.193 Frequencies available.

(a) Except as provided in paragraph (e) of this section, the following frequencies and frequency bands and associated emissions are available on a non-exclusive basis to the indicated classes of stations or units of such stations in the Radio Amateur Civil Emergency Service.

There should be no subband restrictions above 51 MHz.

(e) A repeater in the Radio Amateur Civil Emergency Service may operate on any frequency and associated emission above 50 Mc/s listed in paragraph (a) of this section.

There should be no subband restrictions above 51 MHz.

END

WHAT WILL BECOME OF CW?

Louis E. Frenzel, Jr. W5TOM/3
11287 Columbia Pike
Silver Spring MD 20901

If you look all the way back to the beginning of ham radio and then trace its development up to the present day, you will see some very interesting trends. For purely academic reasons it is interesting to see where we have been. It's like studying history. In addition, by noting the various trends that have occurred, we may be able to predict where we are going. I think that one of the most interesting trends to look at is the use of the various modes like CW, AM, SSB, and RTTY. Statistics are hard to come by here to verify these trends, but I believe we can still make some general and useful observations without them. One particularly interesting phase of this is the history of CW. Let's take a look at the mode trends over the years to see if we can predict what will happen to CW.

When ham radio first began, all we had was CW, first by spark then by normal means as we know it today. As the technology of radio and electronics developed, we soon had radiotelephone by amplitude modulation. The convenience of voice communications made AM popular among hams even though it was more expensive to use, would cover less distance, and was more succeptible to noise. FM came along soon after; it too gained some followers. These gains in radiotelephone work were made at the expense of CW. Those operators that used to work CW, were now working phone or some of both. So as the years passed and radiotelephone became more widely used, CW activity decreased.

I believe it is safe to say that ever since ham radio began, there has been a continued decrease in the use of CW. The major reason for this is simply the continued and increased use of radiotelephone techniques as they are introduced or become more perfected. The introduction and rapid increase in the use of SSB no doubt has taken its toll of CW operators as well (AM operators too for that matter). The equipment manufacturers have helped by making many reasonably priced radiotelephone transceivers, some of which have absolutely no provision for CW operation. That's progress, brother.

There are also other factors that have no doubt influenced the trend of decreased CW activity. For example, in the early fifties the FCC did away with the "Class A" license phone privileges and opened the 75 and 20 meter phone bands to all amateurs. This seemed to have an almost immediate effect of increasing phone operation and correspondingly decreasing CW activity. The increased use of the VHF and UHF bands has probably caused a similar but rather indirect decrease in CW work. As more hams go to these higher frequencies, CW activity tends to decrease. Who uses CW on the VHF and UHF bands anyway?

By just listening to the various CW bands you certainly wouldn't think that CW activity has decreased much. But the somewhat overcrowded conditions are the result of an increase in the total ham population. CW activity as a whole has increased because the total number of hams has increased, but *percentagewise* it has decreased. Today CW is probably in the 30 to 40% usage bracket while phone is in the 40 to 50% range. The total doesn't add up to 100% because some hams use both modes, of course. This overlap plus some of the special modes like TV, RTTY, pulse, etc. make up the difference.

Having noted the trend of decreased CW activity, what can we say about the future? Will CW continue to decrease in popularity or what? What do you think? I'll give you my prediction here.

I sincerely feel that the incentive licensing plan now in effect will produce a slight increase in CW activity. The exclusive band segments are a big incentive for a ham to bone up on his code to get his extra class license. As most everyone knows, one of the best ways to get your code speed up is to get back on the air and work some CW. In fact, this is by far the easiest way. Regular and intense practice with code records or W1AW will get you there faster, but it will be more difficult.

The extension of the Novice license term to two years may also cause a slight increase. With more Novices on for longer periods of time, CW activity just may increase. After all, Novices work CW exclusively.

The slight upward trend will probably only be temporary or will show up perhaps just as a less rapid decrease in CW activity. I think that it is safe to predict a continued decrease over the long term. We'll just have to wait and see.

The Case for CW

Frankly I hate to see CW on the down swing. All things considered it's probably the best mode of communications available to us. It is cheaper and simpler to use than any other mode. Using it, you can cover more distance with less power under noisy and crowded conditions than any other mode. And it's the only way to handle normal and emergency traffic. These obvious advantages are continually overlooked because it's so much easier to just talk. It requires less concentration and skill to operate phone. I don't think most hams give CW a chance. Most consider it little more than a nuisance, something they have to learn in order to pass the license exam. Once they have to learn it well enough to pass the exam, it is virtually forgotten until renewal time. If hams would consider CW in a different light, we might see more activity. Don't look at CW as a necessity or a drudge. Look at it as a rare, if not unique, skill that most other people do not have, and be proud of this skill.

Another point is simply that CW becomes easier and more fun the more you use it. It's like anything else unfamiliar. The more we use it, the more comfortable we become with it and the more we will tend to use it. Get in the habit of using CW and I bet that in a short time you will like it. Your code speed will go up, you will be more adept at tuning and copying, and soon it will all become automatic, like driving a car. You won't consciously think about doing it.

I have found that two items really help to increase the pleasure of operating CW. One is a good electronic keyer and the second is a good selective receiver. With an electronic keyer you can send nearly perfect code. This is particularly appealing to a CW man. A good sounding "fist" really stands out. It's a definite mark of accomplishment. In addition, the keyer itself is intriguing. It takes a little skill and practice, of course, to master one, but yet it isn't so difficult as to cause frustration. Most hams, being incurable gadgeteers, find electronic keyers fun to play with and a challenge to use. If you are not now on CW, buy or build yourself an electronic keyer. You'll go nuts until you can get on the air and use it.

Electronic keyers make a good cheap and easy home project if you are inclined to do things yourself. There has been at least a jillion articles on them over the past ten years or so in the ham magazines, so you shouldn't have any trouble locating a suitable design to build from. On the other hand, if you don't like do-it-yourself projects, there are numerous good commercial units available. Get an electronic keyer and enjoy some CW.

The other item that helps to make CW more enjoyable is good receiver selectivity. The key to good CW reception is to have a receiver capable of separating stations operating near the same frequency. Nothing is more annoying than to lose a good contact to QRM even if his signal strength is very high. An adjacent station can easily wipe him out. However, if your receiver is selective enough, you can probably separate the two interfering stations and carry on a decent QSO.

If your station receiver isn't selective enough, you might consider an outboard Q multiplier or tunable audio filter. These are easy to add and do a good job in providing the needed selectivity. Neither requires extensive receiver modifications. If you plan to operate a lot of CW, it will pay to invest in the most selective receiver you can find to begin with.

What's in Store for CW?

Changes over the years have helped to cause a decline in CW interest. As AM, FM, and SSB became popular and more perfected, CW probably suffered some from loss of interest. However, this is not to say that all of the technological changes going on didn't have some effect on the business of CW itself. It most certainly did. The electronic keyer is certainly one development that we can point to. Not only do we have small, exotic, integrated circuit keyers, but also pushbutton, typewriter-like keyers are available. These offer improved convenience in that no CW sending skill is required. Just push the button and out comes the perfectly formed dots and dashes for that letter.

The opposite of a pushbutton keyer is a device that receives the code and automatically converts it into a visual display easily read by an operator. Such devices do exist, but they are complex and expensive. Their big advantage, like their pushbutton keyer counterpart, is that absolutely no CW skill is required. If you know your ABCs, you've got it made. Numerous code receivers like this have been developed for commercial and military use. They are so expensive that they are virtually impractical for ham use. Nevertheless, I guess if they were available, some hams would buy them. Perhaps with modern integrated circuits, an inexpensive unit could be built.

Even though pushbutton keyers and automatic code receivers are entirely possible, I'm not too sure that they are the answer to the CW question. Since no skill is required, there is really no challenge involved. Of course, this is the way it is with phone operation, so maybe such devices could really go over big. If these units could be made available to everyone at a reasonable price, the FCC could do away with the code test and we could all still operate CW without even knowing it. Transmitters would have built-in keyboards while the receivers would contain CRT, Nixie tube or some other form of alphanumeric readout displays.

In the not-too-distant future, perhaps we will see such things in common use. It will be a sort of RTTY, only using electronic means entirely and the standard international code instead of mechanical devices and the Baudot code. It will be sort of like using a computer. We can put the data in and interpret the output even though we don't know how the computer actually works internally. (Is that the definition of an "appliance operator?")

Somehow I just can't see much of this in ham radio. This takes away the pride and the skill of sending and receiving. And I feel that this is still important.

In conclusion, I say we will continue to see a gradual decline in CW activity. The incentive licensing thing may help to hold it up for a while but in the long run we will see less of it. I get the impression that people feel that it is a thing of the past, an inconvenient, cumbersome, and obsolete method of communicating. Perhaps so, but there is still a feeling of tradition and pride that will help it to hang on for years to come. You'll never experience this feeling yourself unless you work CW for a while. Give it a try. Get yourself a keyer and a selective receiver and have a go at it. You might like it. If you really want to be a pioneer, try CW on 6 or 2 meters. There is less QRM up there, more room to move around in, and CW seems to be ideal for these bands. Since propagation essentially restricts the range you can cover, it makes good sense to use CW to help you reach as far as you can. CW will go a lot farther than phone up at these frequencies. See you there. . . . W5TOM ■

FM-AM Transmitter-Receiver Aligner

Many articles and ideas have been published in recent months which have been slanted toward the VHF FM'er. Most of them have been directed to the attention of the receiver. Little mention has been made of the transmitter.

I have been using receiver peaking and aligning generators for several years now, and since I am in the FM communications business as a profession, I have often wished that I had a small transistorized instrument that would take care of transmitter frequency and loading adjustments along with the receiver peaking.

The gadget I have conceived cannot be construed to be a precision test instrument; however, it does fulfill most of the requirements of the average VHF FM operator.

Basically, it starts off with the usual peaking generator, (a crystal oscillator and multiplier) followed by a diode mixer/detector and an audio amplifier with enough power to drive a small speaker.

The peaking generator, while generating a small signal for receiver alignment, also provides enough signal to the diode mixer to heterodyne with a signal from the transmitter which, when amplified in the audio section, may be used to align the transmitter to the receiver frequency – or any other preset crystal frequency. Simply tune the transmitter oscillator for zero beat in the speaker.

The circuitry also provides for connection of a relative field strength meter.

In addition to its VHF applications, it works equally well in the HF bands. In my unit, I included a crystal for our local 40 meter MARS net frequency.

I chose to use PNP transistors because I had a 5 pound box of them. In the oscillator, I used a 2N384 and it took off strongly as soon as I applied battery voltage to it.

I tried several unmarked transistors in the multiplier and some of them worked pretty well, but the one I wound up using was a Motorola M9029. Upon checking it out, I found that it is commonly used as an rf amplifier in some VHF receivers. I could find no equivalent 2N number for it.

For the multiplier coil, I used 5 turns of 16 AWG centertapped for the collector and an output tap one turn up from the cold end.

The diode mixer/detector was arrived at by "cut and try" also. I still don't know what the number is because there were no markings on it – not even the usual color bands. However, it works well at VHF frequencies and delivers enough output current to drive my field strength meter to the pin (500 µA) at some distance from the transmitter.

For the audio section, I used one of those little Japanese IW units I got from Allied Radio for $4.95, but I could have used the audio portion of one of those little pocket receivers.

5/8 WAVELENGTH VERTICALS

R.L. Crawshaw WAØNGV
1715 Northeast Parkway
Wichita KS 67208

Many articles, manuals and even full-length books are devoted to antennas in general and as specifically applicable to the amateur radio service. Unfortunately, one of the most effective simple antennas for both local ground-wave and long-haul DX communications on the higher frequency bands is almost invariably conspicious by its absence. Consequently, few amateurs are familiar with the characteristics, design, or construction of the 5/8-wavelength vertical antenna.

It will be immediately apparent to most amateurs that the 5/8-wavelength vertical antenna will provide an omnidirectional radiation pattern and a vertically polarized signal. And the antenna itself will be 2½ times as tall as the more familiar ¼-wavelength vertical or groundplane. What will not be so obvious, to the uninitiated, is the even lower angle of vertical radiation, the gain obtainable and an additional improvement in reception due to increased capture area over the conventional ¼-wavelength antenna.

These characteristics have made the 5/8-wavelength antenna very popular in the land mobile services and in amateur 2 meter FM operations where omnidirectional vertically polarized ground-wave communications with low-power mobile stations are desired on a full-time basis.

Vertical antennas, almost invariably of the ¼-wavelength variety, have been widely employed in the amateur radio service for DX communications where their low angle of radiation (assuming an adequate ground

system) has proved very effective. Since the polarization of radio signals is generally rotated significantly in the process of reflection, cross-polarization losses are seldom a consideration in sky-wave communications.

Unfortunately, the additional advantages of the 5/8-wavelength antenna have seldom been employed for normal amateur communications. True, a 150 ft vertical for 75 meters or 80 ft for 40 meters is beyond the facilities of most amateurs. However, a 30 ft antenna for 15 meters is well within amateur capability, and 50 ft (20 meters) is within the realm of reason.

Theory of Operation

As a short grounded vertical antenna is increased in length, the radiation lobe narrows, increases in intensity, and the angle of maximum radiation lowers toward the horizon. As the length exceeds ½ wavelength, a secondary lobe of radiation at high vertical angles develops; but the low-angle radiation continues to increase until a height of 5/8 wavelength is reached (Fig. 1). With no equalizing factor, as the

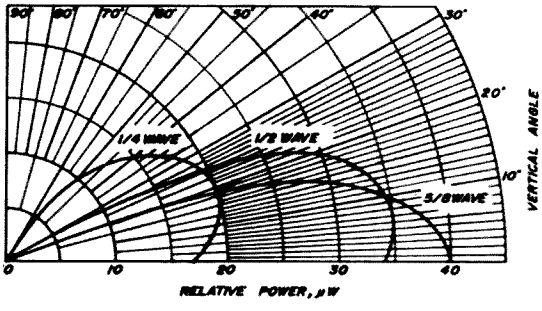

Fig. 1. Low-angle radiation increases as antenna length increases up to 5/8 wavelength.

length is increased beyond 5/8 wavelength, the high-angle radiation increases and the low-angle radiation decreases.

Since the 5/8-wavelength antenna is nonresonant, it presents a highly reactive load impedance unsuitable for direct feeding. At least three basic methods are available to transform this impedance to a 50Ω nonreactive feedpoint.

Probably the simplest method is use of a small series inductance as shown schematically in Fig. 2. The inductance can be

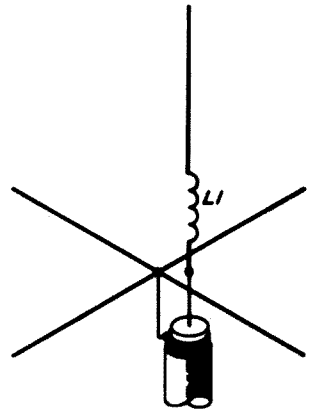

Fig. 2. 5/8-wavelength vertical base-loaded to 3/4 wavelength with series inductance.

considered as base loading the antenna to 3/4 wavelength (with no change in the radiation pattern). This is a resonant length which will present a feedpoint resistance of approximately 50Ω, a very close match to RG-8/U or RG-58/U coaxial cable. Adjustments to the loading coil should provide an swr of less than 1.2:1. In the groundplane configuration, some additional improvement in swr can be obtained by dropping the radials. Approximately 30° below the horizontal will be about optimum with a resulting swr of less than 1.1:1. This configuration has the advantage in simplicity and ease of construction and tuning. It will also be relatively broadbanded when fabricated of materials of adequate strength.

The second feed method utilizes a parallel-resonant circuit tuned to the operational frequency with the feedpoint tapped at a low impedance point on the coil, as shown in Fig.3. This arrangement may be considered as providing high-impedance feed to the base of the radiating element and a direct ground connection to minimize ignition noise and provide a

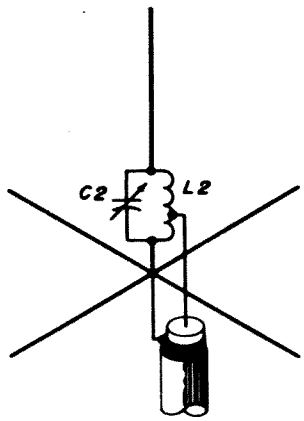

Fig. 3. 5/8-wavelength vertical using parallel-tuned -circuit feed.

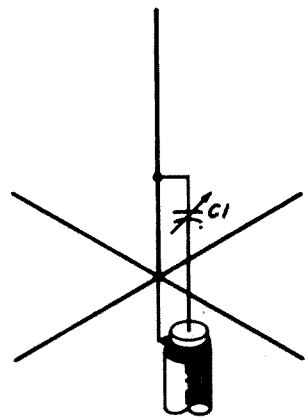

Fig. 4. 5/8-wavelength grounded vertical with gamma match feed.

degree of lightning protection. Coaxial feedpoint tap adjustments in conjunction with minor tuning changes can provide nearly a 1:1 swr at the operating frequency.

The tap point and tuning adjustment interact slightly and initial adjustments are slightly more time-consuming. However, the coil–capacitor combination can be grid-dipped to the approximate frequency on the bench so that only minor touch-up is required.

This configuration has the additional advantages of providing a very low swr without decoupling-radial droop or when mounted on a mobile installation. It will not normally be quite as broadbanded as the first.

A third method of feeding is through the familiar gamma match, as shown in Fig. 4. Here the radiator itself is grounded and the feedline is tapped onto the radiator through a series capacitance. This arrangement also provides a direct ground connection for minimization of ignition noise and a reasonable degree of lightning protection. Feedpoint tap variations combined with series capacitor adjustments can provide nearly a 1.0:1 swr at the operating frequency.

This configuration is particularly adaptable to feeding existing grounded towers as ground system of heavy radials will be required.

Design

The 5/8-wavelength vertical radiator should be reasonably close to a full 5/8 wavelength at the desired frequency but should preferably be no longer. Consequently, the decoupling radials should be a 5/8 wavelength at the high end of the band of operation. Conversely, the decoupling radials should be a minimum of ¼ wavelength at the low end of the operating band. The following formulas are based on reasonable velocity factors for materials probably available in amateur construction and should prove adequate for preliminary design purposes.

$$\text{Radiator length, in.} = \frac{7020}{\text{f in MHz}} \quad \text{or}$$

$$\text{Radiator length, ft} = \frac{585}{\text{f in MHz}}$$

$$\text{Decoupling radial length, in.} = \frac{2880}{\text{f in MHz}} \quad \text{or}$$

$$\text{Decoupling radial length, ft} = \frac{240}{\text{f in MHz}}$$

Using these dimensions, the coupling circuit can then be selected to resonate or provide minimum swr at the desired operating frequency. Though theoretically any coil or coil–capacitor combination which can be resonated at the desired frequency would work, it is important that good tank-circuit design principles and full

weather protection be considered to minimize circuit losses and provide for maximum energy transfer. In general, this implies that all coils be space-wound with large wire or tubing and that length-to-diameter ratios be less than 4:1 (and preferably 2:1). Capacitors should be high quality, ceramic insulated or wide air-spaced variables for ease of circuit adjustment and reasonable power handling capability.

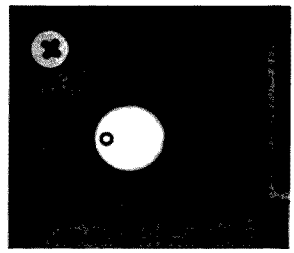
The coaxial feed tap point will vary with different constructional methods and materials and the optimum point must be determined experimentally for each installation. It will invariably be quite close to the ground end of the coil, varying from approximately 1 turn on 2 meters to possibly 3 or 4 turns on 20 meters.

Construction

While this is not intended as a "hardware" style construction article, a few approaches possibly worthy of further consideration have been accumulated.

Conventional TV masting or aluminum tubing is readily available, rugged and inexpensive, although insulation and installation are more difficult than with some other materials.

Of course, the surplus whip antenna segments and their matching insulators are relatively inexpensive, free standing to heights approaching 20 feet; they are relatively light in weight and are available from numerous sources.



Insulated (or even grounded) antenna towers should make effective radiators for the lower frequency bands, providing an adequate ground radial system is incorporated.

On 2 meters or even 6, a fiber-glass fishing pole covered with shield braid from RG-8/U and RG-58/U makes an ideal radiator. Of course, 1/8 in. welding rod works adequately on 2 meters or higher bands also.

Although this antenna will probably not compete with a good beam or quad at optimum elevations above ground, it is a very effective antenna, readily and economically fabricated with minimum facilities.

Feature This

SIGNAL/ONE'S CX7 GIVES YOU
Instant Band Change Without Tune Up.

Remember when . . . you missed that really rare one . . . because he showed up on 10 when you had a hot string going on 20 and couldn't take the time to retune? . . . Or had to move clear across a band to meet a traffic net and were late getting there? . . . Well, if you don't, Signal/One engineers do and did something about it! By putting state-of-the-art technology to work in a:

- BROAD BAND DRIVER . . . **totally solid state and linear from 1.8 to 30 MHZ; it provides freedom from driver peaking adjustments.**
- BAND PASS P.A. **output filters, pre-tuned for every ham band from 160 through 10 meters.**

These remarkable features actually allow band change from one band to any other band in the middle of a sentence without the time consuming tasks of reresonating . . . that's state-of-the-art flexibility.

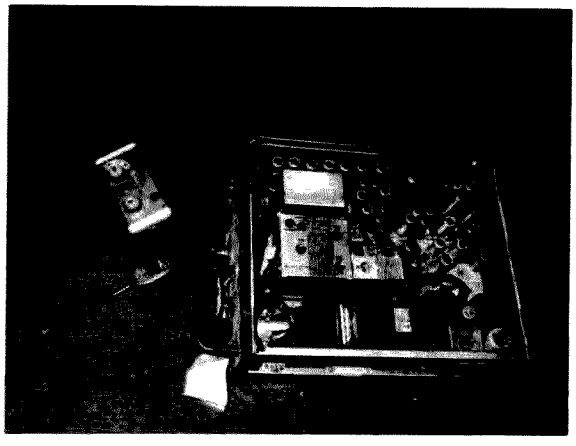
The Intelligent Use of 2 Meters FM

Like canned sardines, today's repeater users are finding themselves cramped for operating time and spectrum.

Peter J. Bertini K1ZJH
257 Elm Street
Windsor Locks CT 06096



The FM mode may have been shelved with the spark-gap had it not been for an FCC action concerning the commercial FM mobile service. Years back when the commercials were growing by leaps and bounds, it became obvious that the available channels were overcrowded. Since spectrum space was at a premium, narrower FM bandwidths were adopted in order to create more channels. Now the wideband equipment had to be converted over to narrowband at a cost which often exceeded the equipment value, or it was junked in favor of new equipment. Many progressive outfits went the latter route. This increased the "surplus" trickle of FM gear to a torrent. And amateurs, the ingenious scavengers that they are, scooped the units up at bargain prices. Realizing the potential use of this equipment, many hams converted the units for 6 or 2 meters or to the 432 MHz region (FM'ers call it "450"). Clubs and individuals got together and fired the units up on the unused higher band edges and thus a major change was born. These units were fixed frequency and the new concept of "channelized" communication was brought into amateur radio. Unlike the equipment used by the early pioneers, the fixed frequency was new to hams and proved to be an advantage.

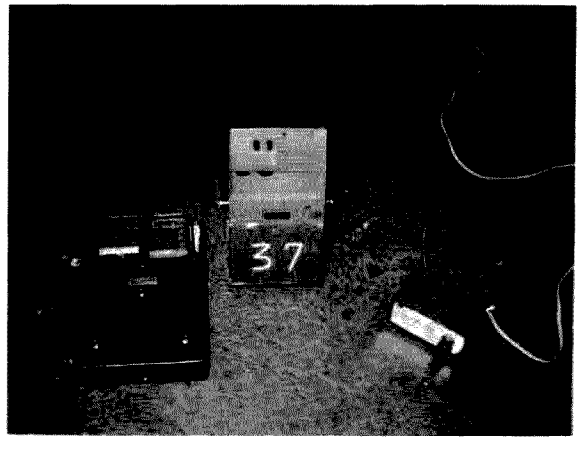
After a while across the country standardized channels were adopted by the various groups. As more gear appeared on the market, more amateurs got on FM. Still the growth was only moderate. It was spurred onward by word of mouth and by curious amateurs who found something besides images on the higher two megahertz of their "Gooneybirds."

Hams, using FM for mobile work, followed the commercials' lead and set up repeaters to extend the range of communications. At first these groups numbered between 3 to 20 hams as a rough average. Then FM started to receive the attention it deserved in the various amateur publications. This brings us to the topic of "The Intelligent Use of 2 Meters FM."

Ed Tilton (ARRL, QST official) once said that repeaters "are self-defeating." There can be a lot of truth in these words, but it doesn't have to be so. What would prompt a statement of this sort? Well, during the last few years FM has been growing in drastic proportions. In the last few years magazine articles on FM increased interest and many

repeater groups found their systems filled to overflowing with new traffic. Many systems fell apart or moved to less populated channels. So it seemed the blessing of channelized communication was actually a curse. This unforeseen problem seems to be more of an operator problem rather than a space problem in most cases. One fact is that an

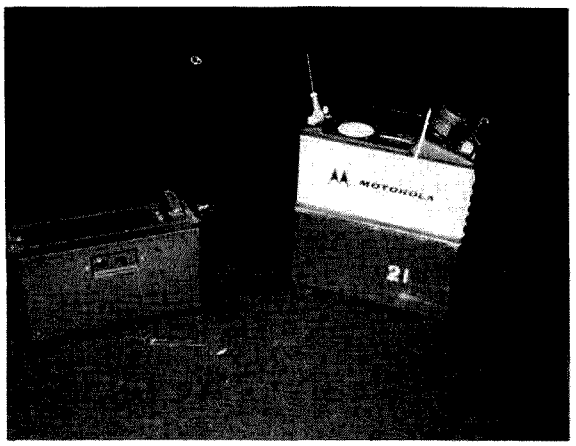
This Motorola trunk-mount rig is characteristic of the two-way units of the '50s. A built-in dynamotor powers the transmitter, while the receiver is driven with a vibrator supply. The control head, shown with mike attached, connects to the unit with a long cable.



amateur obtaining a surplus FM unit rarely equipped it for anything but the repeater input frequency on his transmitter and the local repeater output frequency on his receiver.

Ideally, a ham using a repeater should be able to transmit on the repeater output frequency as well as the input, allowing "direct" operation without using the repeater. The use of a repeater to ragchew with a lone ham across town is stupid. The use of a repeater located 20 miles outside of town to talk across town is equally stupid, and both instances are examples of a lack of courtesy to fellow system users.

Few FM'ers seem willing to upgrade the receiving portion of their unit. They feel that if they can hear the repeater that is all that there is to it. Period. Case closed. What nonsense! Most units at best are only passable for repeater use and almost useless for extended direct work. One interesting point which has not been made is the "capturing effect" where a strong signal will take over a weak one on an FM receiver. The stronger will usually take over the limiters and the weaker is unheard. Let's use our imagination and explore this point further. Suppose we have four hams on an FM channel using identical equipment. Hams A and B live in Getown; and 10 miles away C and D live in Reaville. Between both towns is a repeater on a slight knoll. Ham A can talk to B, and C can talk to D with no interference to each other because of relative signal strengths. Suppose B and A decide to talk to each over the repeater. Certainly A and B can converse via the repeater, but C and D were blasted off channel by the needless use of the repeater!



Please don't get me wrong. I have nothing against repeaters. A well thought out and maintained one is not only a joy to use, but a pleasure to listen to. A repeater requires careful attention for the channels used, and the technical problems would fill this magazine. In many areas the standard channels are so crowded that it would be impossible for a new repeater to go into operation without interference to itself or others. It takes only one lid to reduce a system to shambles.

A ham just getting into the FM game finds a new and strange world when he's first

In the early '60s, transistor units made their appearance. The two shown here are GE "Voice Commanders." The unit out of its holster is getting a battery charge from a GE supply built into a control head housing.

introduced to a repeater. All that is needed to be successful is common sense and some knowledge of the operating procedure used. For instance, you should never hear a CQ called. Common practice would be, "This is K1ZJH mobile monitoring '94' direct" or "K1ZJH repeat via W1BNF monitoring 94." This is all that is needed—if any of the group is around you will "break" their squelch with your call; and if they feel like chatting, they'll let you know. Contacts through a repeater are kept short, especially during "busy" hours when everyone is on the road, say on the way to or from work.

Some of the early portable units, such as this Motorola P33, used "hybrid" circuits, with tube-type transmitters and transistor receivers. The lower half of the unit shown is a ni-cad battery pack, and can be replaced with the ac supply shown at left.

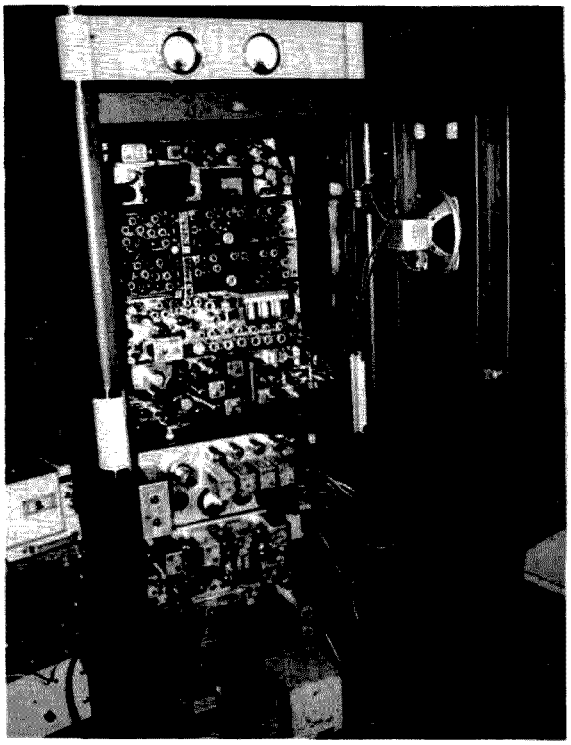
A QSO is thrown back and forth like VOX operation, to a lesser degree. Monologues are frowned upon. This allows a breaker to join or the party to bow out if he has arrived at his destination. Many (indeed, most) repeaters have dropout timers that will shut the system off if a continuous signal stays on the input for over a specified period (usually 3 minutes). Generally speaking, there is no time limit for the use of repeater. It is left up to the intelligent use of the user; the system is left in your hopefully responsible hands.

One very irritating thing new system users seem to enjoy doing is keying the repeater on and listening to it "come back." (Some can sit back and do this for hours.) While most outgrow this habit before long, the repeater operators get "up tight" when they hear someone playing games with their system. If you practice such tactics, you will be labeled as a trouble source.

A prospective FM'er will find, while browsing through the lists of available FM units in the ham magazines, a bewildering array of letter prefixed multidigited units listed with no other description present. The best way to find out what would best serve your needs and pocketbook would be to contact an FM'er who has had some experience. While everyone has his own brand of preference, generally Motorola, GE, and RCA gear are best bets since (1) they are still in business, (2) technical data is easier to come by for these units, and (3) there will always be someone around town familiar with their circuitry. Also, there are schematic sourcebooks on the markets for GE and Motorola gear at present.

Once you select and buy your unit, learn how it works and get familiar with working on it. The number of new hams who can fix the guts of the equipment in their car trunk is sadly deficient. This is one item which cannot be crated up and sent back to Heath!

The first rig you will want to acquire will most likely be a mobile unit for the car. A good mobile starts at $75.00 and units converted to the ham band generally run $25.00 to $50.00 more. Try to do the conversion yourself with the aid of an experienced ham. That will help you learn about the unit. Generally, only a retuning is needed, and sometimes some of the coils may have to be padded to bring them into correct range. The mobile unit might well be considered as your major piece of gear. The quarter-wave whip mounted on the trunk lid or roof of the car is widely used. Higher gain coaxials or 5/8-wavelength verticals rate second and are moderately expensive.



Various stunts can be used to improve the transmitter. Eliminating the dynamotor with a transistor supply and swapping 6146s for 2E26s is a typical modification. Since the average mobile receiver has a sensitivity of 0.7 μV (at a quieting factor of 20 dB), your best investment is a preamp. A Nuvistor job

will bring a 0.7 μV receiver down to 0.5 μV or better in most cases. Reworking the front end will get you down to 0.3 μV or better with a little effort.

If you do a lot of traveling, you may desire to work into the repeater systems in the areas you travel through. The hope for a network of repeaters all on a national input and output is unfortunately impractical. With the number of 2 meter stations currently operating, there would always be someone from system A getting into system B and vice versa. Cooperating between groups has not always been in the ham spirit Paul Segal wrote about, either. The frequencies of 146.34 MHz in and 146.94 MHz out seem to be the most commonly used for repeaters (see Repeater Directory in this issue). On 6 meters, 52.525 MHz is considered to be the main repeater output channel.

W1BNF, the repeater which serves Central Connecticut, recently added a 146.37 to "98" repeater system. The 146.37 MHz channel had to be created because there were no more available channels in the populous New England area! What this boils down to is that you may have to "multi-channel" your unit so that you can take advantage of all of the systems you will want to use or have access to. To do this, some hams stop their cars, go to the trunk, and manually change crystals as they get into different repeater areas. This is acceptable so long as you don't have to do so often or on superhighways. Crystal switching can be done by diode networks, relays (reed relays are ideal), or remote oscillator decks. Commercial units having more than two crystal positions for the receiver or transmitter are rare and expensive.

Most hams, after being on FM a while, eventually desire a base station for home use. Base stations which do get into the ham market command high prices; however, converting a mobile unit for base use is relatively easy since the power supply is the only major modification to be made in such instances. Motorola has provisions for separating its series into three discrete sections: receiver, transmitter, and power supply. A receiver may be removed from a mobile unit and used as a base receiver. Several months later it may be used as a mobile unit by simply inserting it into the mobile case. These "strips" (as they are often called) are

The large base stations usually have sufficient room to contain not only a complete repeater, but the control equipment and UHF gear as well. This rack contains 2 and 6 meter FM equipment as well as power supplies and "link" equipment.

available for quite reasonable sums. Since Motorola (and some others) generally uses the same series of crystal frequencies for their entire line of transmitters, it might be advisable to employ the same make unit in the base as the car. Receiver crystals don't always follow this rule because of different i-f configurations.

In the past few years, a series of hand-held units (dubbed "bricks" because of their size and shape) have been hitting the market. These solid-state wonders are very popular among hams because they were made surplus in commercial service by the advent of even smaller units, containing integrated circuits. The bricks sell in the $300.00 bracket and are made by Motorola. These units make ideal second rigs because of their portability and convenience. But without a repeater,

VHF FM MONITOR RECEIVER

NEW

100% MADE IN U.S.A.

Only $79.95 Postpaid in the U.S.A.

The new **VANGUARD FMR-150** is not just another frequency converter but a complete FM receiver with outstanding performance.

Check the following features and see why it's the best. Collins IF filter for separating those closely spaced stations you hear together on other sets● Double conversion to eliminate interference from image frequencies● Dual Gate MOSFET RF stage for low noise. .2 uv. sensitivity, and minimum cross modulation● Automatic squelch for eliminating noise● Self-contained speaker● Operates on 12v. D.C. negative ground● Heavy gauge anodized aluminum case 6" x 7" x 1-3/8"● Provision for 4 crystal controlled channels at the push of a button● One channel of your choice supplied with receiver. Additional channels available just by plugging in another crystal at $4.95 ea. No need to buy another RF unit as in some other sets● Factory tuned to cover any 6MHz segment from 135 to 175 MHz.

HOW TO ORDER: The **VANGUARD FMR-150** is available only direct from our factory. Include remittance in full plus sales tax if you reside in N. Y. Be sure to state the 6MHz segment you will want to cover and the exact push button frequencies to be included.

VANGUARD LABS Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

their utility would be sharply reduced. At any rate, the brick can be a lot of fun if some of your friends jump on the bandwagon with you.

High-power solid state mobile gear made by all the big manufacturers is now hitting the ham market in small quantities (but usually at prohibitive prices). Watch for price breaks in the next few years on these items. (I was going to get one, but it was worth more than the car.)

As a final note, I should mention the equipment which has come out in the past year for ham use. These units are generally all solid state and sport multifrequency, small size, battery operation, and several other features. The price is around $300.00 for the latest one I have seen. The Galaxy people have marketed a unit for under $200.00 which, besides all of its other extras, offers variable speech clipping!

This article should familiarize the uninitiated with at least the basic rudiments of FM operation. I hope I have helped the beginner avoid some of the common pitfalls which he might have otherwise stumbled into.

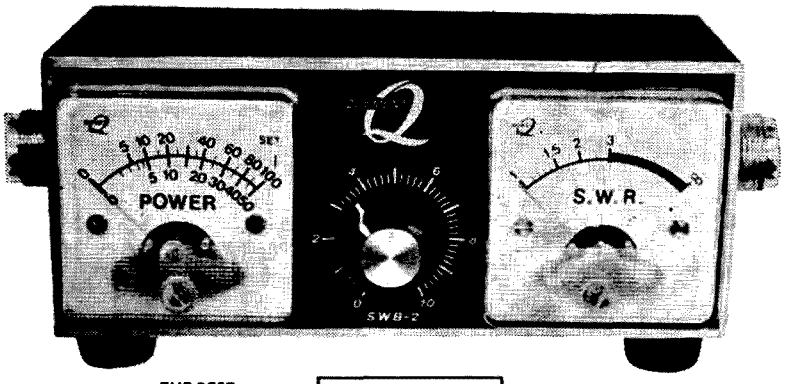
...plus 10 dB...

A lot of ham operators toss around the decibels quite knowingly, but behind this facade of glib gab, there remains the simple fact that some of the best talkers really don't know what's going on. You can hear it on the air every day, "You're 40 over S9, old man, and this receiver has a very scotch S-meter." In case you don't completely comprehend all this, please don't feel too badly, for there are quite a few young hams – and a few oldtimers – who don't dig this "dB" stuff too well. Years ago, when I was a newcomer to amateur radio, the subject appeared fascinating, and equally incomprehensible.

For simplicity's sake, let us confine our remarks to decibels (dB, to abbreviate correctly) that deal with power ratios. Decibels expressed in voltage ratios may be of interest to phone company personnel, but most ham operators are thinking of their rf output, or lack of it, and that's measurable in watts. We can generalize by stating that the decibel is a nonlinear, or logarithmic, concept. Let's take a specific example. A 100W signal shall be our norm. On this basis we can run up the signal by +10 dB, and we now have a 1000W signal. Okay so far? By the same token if we reduce power to 10W from our 100W norm; we have gone down by 10 dB.



A little bit of history in the matter may set things into better perspective. The bel is a sound power unit, originated by the telephone company people. Clumsy in size, it got cut down to a more reasonable size of 1/10 bel, or *deci*bel. One decibel is the smallest amount of difference in sound power that can be recognized by the trained ear on a wire circuit having normal characteristics. Generally speaking, the rf transmission of power through the air involves fading, atmospherics and interference. Due to this combination of QSB, QRN, and QRM it is generally acknowledged that it takes 3 dB of power change (either up or down) to be noticeable. A 3 dB change in power can be noticed by an experienced operator; this would involve a 2 to 1 change in power, that is either in increase or a decrease.

After reading all this jazz in textbooks, handbooks, and hearing about it over the air, I grabbed hold of a war-weary surplus Variac, and one of the 40 meter ARC-5 "Command" transmitters. I then proceeded to contact a friendly ham about 8–10 miles away. This was strictly groundwave stuff, and to make sure of stable conditions, the QSO was held at 2:30 in the afternoon of an early summer day. The DX was all of 10 miles maximum, as previously mentioned, and most of this was over water. With a little patience, we spotted a clear frequency, and proceeded to run the power level up and down. The ham at the other end was very helpful. You know what happened? He consistently gave me reports which closely agreed with all that stuff in the theory books. All the results were written down in an old logbook, almost twenty years ago.

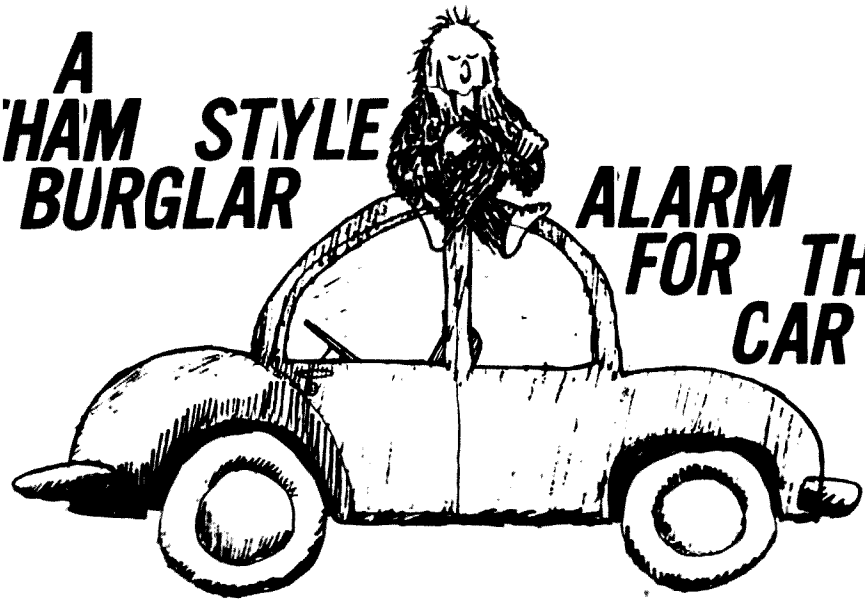
1000 SOUTH BASCOM AVENUE SAN JOSE, CALIFORNIA 95128

"Northern California's Most Complete Ham Store"

With respect to RST reports, just remember that most hams agree that one S-unit involves a power change of roughly 6 decibels. That is, a 100W rig would have to go up to 400W to get a 6 dB change upward. Each time the power doubled, we add 3 dB to our calculations. The first increase from 100 to 200W netted a +3 dB, and doubling again from 200 to 400W added another 3 dB to the signal. Results: power quadrupled, and signal reports up by one S-unit. Sometimes it makes you wonder if antenna work might not pay off better, doesn't it?



Another way of looking at the whole darned argument is to think about the big money makers in radio, the broadcasters. When a station owner or manager has the opportunity to increase his power, does he go for an increase of 100%? He does not! He wants to be noticeably louder, so that he can sell all those prospective sponsors the idea that he is now "much louder." The way it's generally done is to run the 1 kW broadcast rig up to 5 kW – or the 10 kW outfit goes to 50 kW. These station management people are in it for money – that's the name of the game – and to make a "noticeable improvement" in their signal strength, they usually go up in power by approximately 5 times. This roughly coincides with our illustration above, whereby the 100W ham rig is increased to 400W to get an S7 signal report up to S8.

A quick summary. Doubling (or halving) power gives us a 3 dB change. Making a 4x change – either way – gives us a 6 dB change, or one S-unit. Running a 100W rig up to 1 kW will give a 10 dB gain in power. This amounts to an increase in S-meter reading of about 1.6 units. To put it in a humorous vein, the poor little ham with 100W of power is way behind the commercial station running 10 kW. . .or is he? Look at it this way: There is a difference of 10 dB between 100W and 1000W. Another 10 dB difference between 1000W and 10 kW. That's a 20 dB total difference. But in S-units it only figures out to be about 3.3 S-points on our meter (that is, if you figure 6 dB to each S-meter unit). This may seem startling, but that's the way it is!

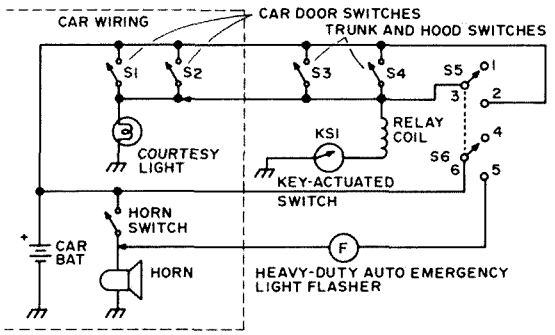
A HAM STYLE BURGLAR ALARM FOR THE CAR



Each month I see announcements about stolen mobile rigs. Until recently the only deterrent to auto burglars which I used, was a warning sticker and a fake key-actuated switch on the side of my car. Several weeks ago I took the mobile rig into the shack for a much needed overhaul, leaving a Heath swr bridge on the floor of the car, where it couldn't be easily seen. The car was parked right in front of my house, and I confidently went about working on the transceiver knowing full well that no self-respecting thief would bother my four-door hardtop for the price of an swr bridge. The fact that my car needed greater protection was brought home to me the next morning when I discovered that my bridge was gone. The crook had wedged a coathanger between the front and rear door windows and used it to pry up the door-locking button. I installed the alarm described in this article, and it has proved very satisfactory to date. It can be duplicated for about $5 (and even less if you have a well stocked junkbox). The alarm will cause your car horn to beep on and off if a door or the hood or trunk compartments are opened, and the horn will continue beeping until you reset the alarm.

The sensing devices used are the car's own door light switches. The contacts of these switches are easy to reach and provide a convenient place to tap power for the alarm. These switches can turn on your alarm and still be used in their intended manner. If your car's rear doors are not equipped with these button switches, you may add them by drilling the appropriate sized holes, and mounting them by the rear doors in the same way as the front switches. At the same time you should mount one in the hood compartment and one in the trunk and wire these in parallel with the others. They should, of course, be positioned so that they are controlled by opening and closing these compartments. These switches cost about 50 or 60 cents at your favorite auto supply shop. You will have to unscrew some of your car's interior molding or trim, and feed the wires under the carpeting of the car. When you are done, opening any of the doors, the trunk, or the hood should cause the interior lights to go on.

The master control on/off switch is usually a key operated one, and may be purchased from Lafayette radio for a few dollars. It should be mounted convenient to the driver's door, and it is best to locate it so that is is covered on the inside by some sort of trim, so that one cannot just open the door and rip out the wiring. I was lazy and installed mine in the trunk com-

partment, but this is not a good practice. If you are super cheap you can use a single-pole toggle switch and mount it inside the door to the gas filler cap, where it won't be seen. Some people have suggested that a spark from the switch could ignite gas fumes, but 99% of the time there is no current going through the switch when it is being thrown. (*But stand by for that last*

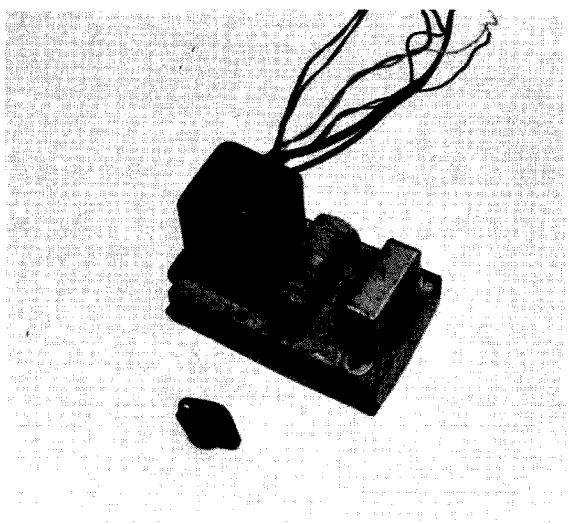
S1, S2 *Car door switches*
S3, S4 *Additional switches for trunk and hood*
S5, S6 *Relay contacts.*
KS, *Key-actuated switch*
F *Heavy-duty auto emergency light flasher*

hundredth. – Ed.) A popular spot for the key-actuated switch is behind the headlights on the front fender.

And now, about the circuit. As you can see from the diagram, the door light switches will supply 12V to the interior lights when the car door is opened. They can also provide 12V to turn on the dpdt relay. Contact with these switches is best made by removing one of the switches from its mounting and tapping into the wires connected to it, using wire nuts. When the relay is actuated by these switches, one set of its contacts closes and is connected so as to provide continuous voltage to the relay coil even after the door switch is turned off. Only turning off the main switch will release the relay. The other set of contacts on the relay goes in parallel with the horn switch. The wires from this switch can be traced from the steering column. When the relay is activated the horn will go on. The heavy-duty emergency flasher is used to make the horn blast on and off, a distinctive sound which will tell you that you are hearing your car, and not just another irate motorist.

Any type of 6 or 12V dpdt relay will serve this purpose, providing the contacts aren't too small. I used one which was mounted on an octal base, and mounted the whole assembly on an L bracket under the dashboard. There is nothing critical about the construction. Details of feeding the wires through the car and opening your car's interior moulding will vary with the particular car.

There are several drawbacks to this particular system, the main one being that if your car is tampered with and you aren't around, chances are good that you'll wind up with a dead battery. But, into each life a little drain must fall. It's very easy, of course, for the thief to open your hood and disconnect the two horns when he hears them go off. With a little ingenuity you can make this inconvenient for him. Or, buy a used horn from your local junkyard and mount it in or under your trunk, and wire it in parallel with the others. Your unwanted friend will go crazy trying to find it, and this will also make a good warning signal for those nasty people who are always standing in back of your car when you have to back up. Some bad guys like to get under your car and cut your battery cable before the alarm goes off. You can cover your battery cables with shielding from BX cable. It is flexible and can only be cut with a hacksaw. Only the very hippest auto burglars carry hacksaws.



There are many other variations and sophistications for this alarm system, including a tape-recorded message which tells the guy what you think of him. With a little effort all the headlights can be made to go on and off. To complete the job, a few warning stickers can be added to your windows and the door-lock buttons can be changed to smooth cylindrical types which can't be pried up from the outside. There is practically no limit to what you can do. But remember, no matter what you design, there is a thief somewhere who, if he really wants to, can still get around any alarm system.

POWER SUPPLIES from SURPLUS COMPONENTS

Clifford Klinert WB6BIH
520 Division Street
National City, CA 92050

This article originally began as a brief description of a small power supply intended to deliver 22½ volts at a few milliamperes for a transistorized preamplifier. However, because of the wide variations of the components available and the desires of builders, it was decided to extend this article into as complete a description as

possible of power supplies in general. The main objective, of course, is to allow the builder to design his own power supply to fit his own needs. However, it is strongly felt that most readers will want to know what they are doing, even if they can do it quite well. It is for this purpose that all attempts have been made to include explanations or derivations wherever it is possible, especially where a concept is so logical and uncomplicated that it is easier to simply know why or how it works rather than to memorize meaningless formulas or circuits. So, actually this project had a much earlier beginning, with the destruction of about ten dollars' worth of silicon diodes. Its final success was achieved after a college course in electronics engineering, and the most useful information is described in this article.

The Transformer

If the builder has an adequate power transformer for the desired project, he might skip this section. However, the desired voltages at the desired prices are not always available, and if the power requirements are

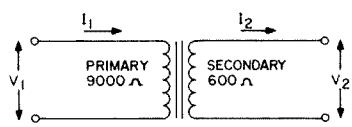

Fig. 1. Schematic of a typical audio transformer and its parameters.

small, an interesting substitution can be made.

Several audio output transformers were obtained from surplus, but they all had a 600 ohm output impedance, and were unfit for driving a speaker. At the same time a six transistor audio preamplifier was hungrily earing up 22½ volt batteries. It soon became apparent that the cost of replacing batteries could easily exceed the cost of the preamp. Store-bought power transformers are also costly, compared to the low priced epoxy

transistors. It was finally decided to try an experiment.

A schematic of a typical transformer and its parameters is shown in Fig. 1. By assuming the transformer to be 100% efficient, we write the equation for the power in the primary and secondary.

$$P_1 = P_2 = I_1^2 Z_2. \qquad (1)$$

The subscript 1 indicates primary, and the 2 indicates a secondary parameter. Equation one says that the power in the primary equals the power in the secondary, which is

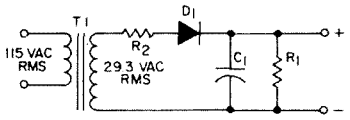

Fig. 2. Half-wave rectifier circuit.

equal to the current squared multiplied by the impedance. If we now use algebra, and divide equation one by Z_1 and I_2^2, equation two will result.

$$\frac{I_1^2}{I_2^2} = \frac{Z_2}{Z_1} \qquad (2)$$

Now the impedance ratio is expressed in terms of the currents. Since we know that current is voltage divided by impedance, a substitution can be made for I_1 and I_2.

$$\frac{I_1^2}{I_2^2} = \frac{\frac{V_1^2}{Z_1^2}}{\frac{V_2^2}{Z_2^2}} = \frac{Z_2}{Z_1} \qquad (3)$$

By manipulation of equation three (dividing it out), equation four is obtained.

$$\frac{V_1^2 Z_2^2}{Z_1^2 V_2^2} = \frac{Z_2}{Z_1} \qquad (4)$$

If equation four is now divided by Z_2^2, and then multiplied by Z_2^2, the final result is obtained.

$$\frac{V_1^2}{V_2^2} = \frac{Z_1}{Z_2} \qquad (5)$$

Now that equation five is established, it is possible to find the voltage ratio in terms of the impedance ratio.

This derivation was given to show how equation five could be obtained if it were forgotten or was unavailable. This is assuming Ohm's law is known and a knowledge of basic algebra is available.

Equation five can be made more useful by dividing both sides by V_1^2, and inverting the result.

$$V_2^2 = \frac{Z_2 V_1^2}{Z_1} \qquad (6)$$

To obtain V_2, we take the square root of both sides of equation six.

$$V_2 = \sqrt{\frac{V_1^2 Z_2}{Z_1}} \qquad (7)$$

Equation seven is the final result, and the output voltage of our transformer can now be found.

V_1 is 115 volts, the line voltage, and Z_2 and Z_1 are 600 and 9,000 ohms, respectively. Plugging these values into the formula we get:

$$V_2 = \sqrt{\frac{(115)^2 (600)}{9{,}000}} = 29.3 \text{ volts} \qquad (8)$$

Thus, if 115 volts is put into the primary, 29.3 volts will come out the other end, and it can be rectified and dropped down to 22½ volts.

Designing the Rectifier

There are two primary factors that work together to destroy silicon diodes; excessive voltage and excessive current. An example of each of the most common circuits will be discussed, and the ratings required for the diodes will be determined.

The simplest rectifier is the half-wave circuit shown in Fig. 2. Assuming that the reader is familiar with this circuit, we shall proceed to find the *peak inverse voltage,* or PIV required for the diode. Since the RMS, or effective voltage, is given for the transformer, the peak voltage must be found. The reader must remember that this is a sine-wave voltage where the voltage varies from zero to some positive peak value, goes back to zero, goes to a negative peak value, and finally back to zero sixty times each second. A complete mathematical proof would require the use of calculus which is beyond the scope of this article, but a reference is given.[1]

The peak voltage at the secondary of the transformer is the effective voltage multiplied by the square root of two.

$$\sqrt{2} \times V_2 = 1.414 \times 29.3 = 41.4 \text{ volts peak.} \qquad (9)$$

Let's assume that R_1 in Fig. 2 has so high a resistance that C_1 charges up completely to the peak voltage, 41.4 volts, and does not discharge. Also, we shall assume that the top of the transformer secondary winding has reached its peak negative value of -41.4 volts. By adding the voltages, we can obtain the equivalent circuit of Fig. 3,

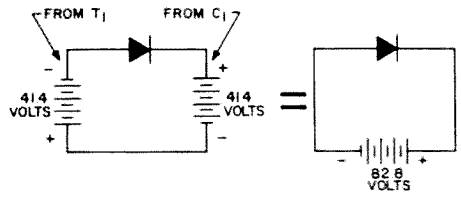

Fig. 3. PIV equivalent circuit.

with 82.8 volts across the diode in the reverse direction. Recall that conventional current is from + to - in the circuit connected to the voltage source. Since current flows in the diode in the direction of the arrow, if current were flowing in the diode, it would be in the reverse, or inverse direction. This indicates a peak inverse voltage of 82.8 volts in this case. To survive, the diode would have to have a PIV of 82.8 or more volts. We always design equipment with a safety factor to prevent unexpected changes. If a safety factor of 50% were used, 50% or 82.8, or 41.4 would be added to 82.8, giving 124.2 or more volts as the desired voltage requirement.

The current rating that is most often given for a silicon diode is for the current that it will be passing under normal continuous operation. A safety factor should also be included here, but there are much higher currents that are present only for a short period of time. Suppose now, that the circuit of Fig. 2 has been turned off for a long period of time. C_1 will be completely discharged by R_1. Assume that the circuit is turned on at the instant in the ac cycle so that a positive peak voltage suddenly appears at the top of the secondary winding of T_1. Since we know that the voltage across a capacitor cannot change instantaneously, the capacitor will appear as a short circuit for an instant. In effect, R_2 and D_1 will be in series across 41.4 volts for a very short period of time. If R_2 is a small resistance, a high current will be forced through the diode. This is the reason a resistor is usually seen in series with diodes in a power supply. Since the internal resistance of the diode is usually very small, it is assumed to be zero, and a resistor is inserted in series to take up the surge. The resistance is determined by Ohm's law, with knowledge of the peak secondary voltage of T_1, and the allowable surge current. R_2 is usually somewhere between 20 and 40 ohms, so by picking a value, say 30 ohms, we can find the allowable surge current. By plugging values into the following formula we get:

$$I = \frac{V}{R} = \frac{41.4}{30} = 1.38 \text{ amperes surge.} \quad (10)$$

Now, this is a relatively low surge current because diodes with a few hundred milliamperes of continuous forward current rating can have a surge current of ten to twenty amperes or more.

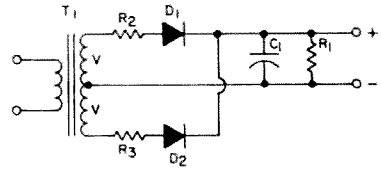

Fig. 4. Full-wave center-tapped rectifier.

Figure 4 shows the full-wave rectifier. Of course, this circuit can only be used with a center tapped secondary, so it would be useless with the transformer that was available. It gives a smoother output waveform that is easier to filter, and a short discussion of the PIV should be included.

Figure 4 is a familiar circuit, and just a glance will show that it is actually two half-wave rectifiers fed 180° out of phase by the transformer. The output is connected in parallel across C_1 and R_1. As in Fig. 2, the peak inverse voltage is twice the peak value of each half of the secondary plus a safety factor. The reader should go through Fig. 4 as we did with Fig. 2 to satisfy himself that the result for the PIV is correct. Also, the surge current can be determined in a similar manner as was done for the circuit of Fig. 2.

Now, we turn to the circuit of Fig. 5, which is the circuit most likely to be used for the application we desire. In order to

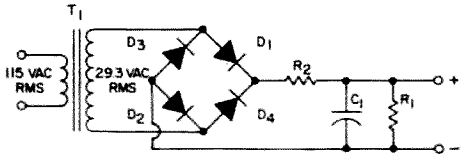

Fig. 5. Full-wave bridge rectifier.

study this circuit it will have to be divided into two parts, one for the positive, and one for the negative half-cycle of the ac voltage.

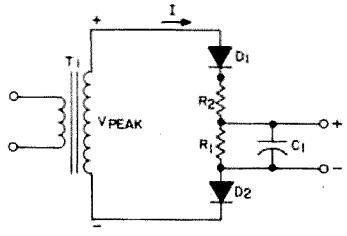

Fig. 6. Positive half cycle of the full-wave bridge rectifier.

Fig. 6 shows the half-cycle in which the top of the secondary of T_1 is positive. Note that the diodes that do not conduct are omitted from Fig. 6 because they act as open circuits. We now have a much clearer simplified circuit that will show how the full wave bridge works. R_2 is the surge limiting resistor and will have a value of:

$$\frac{V_{peak}}{I_{surge}} = R_2 \text{ (surge resistance)}. \quad (11)$$

V_{peak} is the peak voltage at the secondary of T_1, and since the diodes act as direct shorts, a current, I, will flow through the diodes, R_2, and R_1, and C_1. Also note that C_1 is considered to be a short circuit for the surge calculations as was done before. I_{surge} is the allowable surge current that passes through the diodes if the circuit is turned on at a voltage peak. The reader has probably noticed that since the diodes offer a short circuit during the half-cycle that is being described, a dc voltage will be generated across R1 and CI that will become the output voltage, V_{dc}. Now, take a look at Fig. 7, the negative half-cycle simplified circuit. If the reader traces the path that the current travels through D_3, D_4, R_1, and R_2, it is easy to see that this is the correct equivalent circuit. In fact, Fig. 7 is just Fig. 6 turned upside down when the transformer polarity changes and the diodes act as a double-pole double-throw switch to keep the

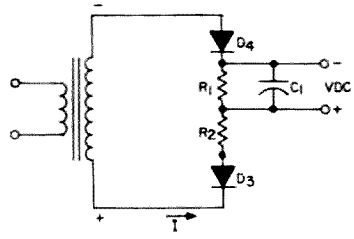

Fig. 7. Negative half cycle of the full-wave bridge rectifier.

current flowing through the load (R_1 and C_1) in the same direction in both half-cycles.

To find the PIV for each diode, assume that the secondary of T_1 in Fig. 7 is at its peak voltage in the opposite polarity. Also assume that C_1 is charged to the peak voltage of T_1, and there is no voltage drop in the diodes or R_2. The voltage drop will be small because the current is small. Now, showing only the diodes and the voltages, we have the equivalent circuit of Fig. 8. This shows how the voltages add to make up the maximum peak voltages across the diodes in the reverse direction. Since there are two diodes, the voltage divides equally between them[2], and the voltage across them is V_{peak}. This is one-half of the voltage of the diodes in Fig. 4, so lower PIV diodes may be used, but twice as many are needed.

If the same transformer is used, the peak voltage (from equation nine) is 41.4 volts plus a 50% safety factor. The PIV would have to be at least 41.4 + 20.7=62.1 volts peak.

If diodes are to be placed in series to obtain a higher overall PIV rating, something must be done to equalize the voltage drop across each diode. All diodes are different, and one will pull more current than another, resulting in one diode having a large voltage across it which causes it to break down and short out, throwing all the voltage across the other diode, or diodes, and eventually the whole string of diodes is destroyed. This was a common happening when the builder was unaware of the real meaning of PIV. Since they short out rather than burn open, the

transformer can be burned out if it is not fused.

To prevent this, voltage dividers can be placed across the diodes to provide equalization. Since the diode is operating in its reverse direction, (very, very small current flow) the internal resistance of each diode is very high, and resistors between 100K ohms and 500K ohms can be used across the diodes to provide equalization. 220K ohms is a typical value. Capacitors across the diodes can also be used, but can be more expensive. One should be careful to calculate the required power or voltage rating for the type of equalization system to be used. It should be noted here that it is often less expensive to use higher PIV diodes and fewer resistors, particularly when inexpensive surplus diodes are used.[3] Determine the cost per PIV ratio for each kind of diode, and be sure to include the cost of equalizing resistors when making the choice.

Filters

The value of filter capacitors and chokes, and the size of the load will in general determine the output voltage and ripple content. This is, of course, depending upon the type of circuit and transformer used. It is possible to calculate these values, but a number of factors are listed that would preclude a detailed discussion of this.

1. Very precise results are usually not necessary in amateur work.
2. Any parts that are available will probably be used if they look as if they will work, regardless of their values.
3. The actual value of a commercially made electrolytic capacitor may vary by as much as 60% from its marked value (check the label).
4. No serious damage will result from experimentation so long as the voltage ratings are adequate.
5. It's easier to put it together and try it than figure it out, in most applications, and more reliable (no math errors).

Also, it should be noted that charts and graphs are available which can give a rough idea of what the ripple content from a certain type of rectifier will be.[4]

Final Comments

The circuit of Fig. 5 was used in the power supply shown in the picture. The filter system used a capacitor input system with capacitances of 40 μF and a choke of unknown value. The diodes were 1N92s with a PIV of 200 volts and a 25 ampere surge rating. The continuous current rating was 100 mF, so all ratings were adequate. It works very well.

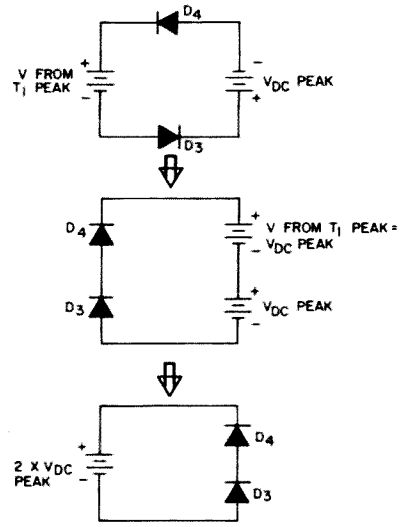

Fig. 8. PIV equivalent circuits.

The main objective of this discussion has been to provide information that can be used to safely construct any type of power supply from whatever components are available, and little emphasis was placed on any particular circuit or design. It was decided to use this approach to allow the reader to design his own power supply rather than having to dig through countless articles to find one that will give him what he wants that he can build with the components that he has on hand. Also, the reader appreciates the satisfaction to not only design his own equipment, but to actually know how and why it behaves as it does.

Selectivity has come a long way.

Today we take for granted shape factors and ultimate rejection figures that were considered either impossible or extremely expensive twenty years ago. Practically all single sideband equipment has a pretty good filter network in the I. F. system to establish the selectivity pattern. It may be a high frequency crystal lattice network, or the lower frequency mechanical type.

There are three factors about the I. F. filter that determine how well it will do its job. The one most commonly recognized is the width of the passband, usually measured at a point 6 db down from minimum attenuation.

This bandwidth is what determines the audio frequency range you can transmit and receive through the filter. The wider the passband, the wider the range of A.F. It becomes necessary, of course, to choose a happy compromise between a narrow bandwidth to help reduce QRM, and a wide bandwidth which will provide more natural sounding voice quality. You'll find that the Swan filter has a 2.7 kc bandwidth. This gets us into another subject which we'll discuss another time.

Shape factor is the next consideration in measuring a filter's quality. This is the ratio between bandwidth at 60 db and 6 db down, and is a measure of how steep the attenuation curve is outside the passband. This factor is often referred to as "skirt selectivity." The narrower the passband at 60 db down, the better the filter will attenuate strong adjacent channel signals. A good crystal lattice filter will have a shape factor of 1.7 to 2.0 depending on its center frequency. Best shape factors are achieved right around 5 mc, which is one of the important reasons for Swan's I. F. system being at 5.5 mc. On the other hand, the lower frequency mechanical filters don't have quite as good a shape factor as high frequency crystal filters, a fact which isn't very well known, and may come as a surprise to many.

Ultimate rejection is the third, but certainly not the least important measure of how good the filter is. All filters eventually "flare-out" at the base of their attenuation curve. This tells you how much the filter will attenuate signals which are 10 or more kilocycles outside the passband. If you have a base attenuation level which is down 80 db, for example, a strong local signal may very well come through the receiver over quite a large portion of the band, and it won't be his fault! There's no point in telling him how broad he is if it's your filter that's falling down on the job. A good high frequency crystal filter having 6 or 8 poles will reach ultimate rejection levels of 100 db, or more. Here again, filters in the 5 mc region are better. So, all you happy Swan owners may as well know the facts and blow your horn a little. CF Networks has made that beautiful precision filter that's installed in your rig, and it's really a dandy.

The accompanying graph illustrates clearly what we've been talking about. But so far we've only been discussing the "standard" Swan filter, and comparing it with other typical 9 mc crystal filters and 455 kc mechanical filters. In case you hadn't noticed, there's a tall, skinny curve on the graph that's all alone. This is the new SS-16! Made exclusively for Swan by CF Networks, this 16 pole quartz filter network establishes a new standard of comparison. Shape factor of 1.28, ultimate rejection greater than 140 db! A giant QRM killer, the SS-16 wipes out strong adjacent channel interference with unprecedented attenuation. And in transmit mode, unwanted sideband and carrier suppression are both increased greatly. For a new experience in Super Selectivity, install the SS-16 in your Swan Transceiver. They are available for the current 5.5 mc, I. F., or the earlier 5.175 mc I. F. system. Installation and adjustment is quite simple, and our famous customer service department is, of course, available for assistance if required.

Sorry, the SS-16 is only available for Swan transceivers.

RF RIVIERA STYLE

Being an electrical engineer and a ham, I have for many years maintained the one-eyed "Gooneybox," Gonset 6 meter Communicator in my cars, changing every year or so to a newer model car and with the change, moving all the ham gear into the new car.

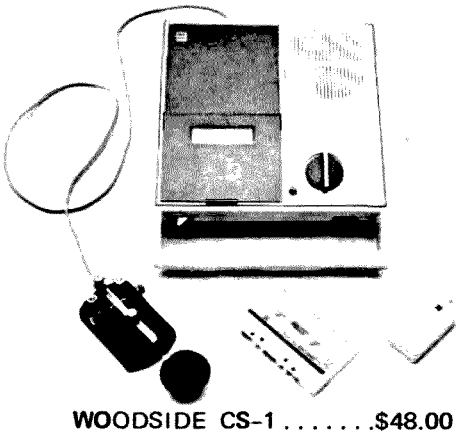
For years, I had no trouble changing the rig from one car to the next until last December when I leased a 1969 "loaded" Buick Riviera. This car is truly a beautiful "mechanism" and I could hardly wait till I could transfer the "Halo," install the Communicator, and start transmitting. The Communicator fitted well over the hump of the transmission – and, after attaching the coax, I started up the engine and turned on the rig. I was greeted with a noise level like nothing I had heard before. I might as well sit beside the battleship Wisconsin while she fires a broadside. I was unable to hear a thing! I was getting hash which sounded like it was about 80–100 Hz. There must be something wrong with my rig, I deduced! After all the years it has been in use, it probably has blown its cool. I turned off the engine and the noise level went away. Nothing serious. Something probably was not grounded properly.

For the next five days I bonded, sealed, and tightened every possible joint and connection. But the noise was still there when I turned the engine on.

Several months passed and it was in the spring that I finally wrote the Buick people explaining my problem. It took 1½ months for them to come up with an answer which I had already tried. I had reached an impasse!

Again, I surveyed the entire car and tested for various "leaks," searching with a "sniffer." Sure, I could pin down the area of the noise; but now, while the engine was running I had, one-by-one, disconnected just about everything – yet the noise persisted.

More months went by and by this time I was getting old and feeble and my "Riv" still had not stopped "generating" a noise. Then, sitting down in the car one day, I started the rusty brain clicking. Why was my car different? What did my car have that made it so different? What was it that pulsed or vibrated even when the alternator, voltage regulator, and everything that could be disconnected *had* been dis-



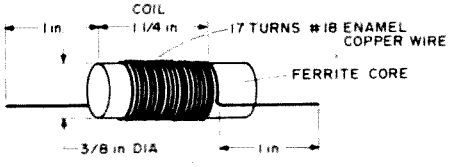
The COMPLETE Code Practice System

MOST CODE PRACTICE SYSTEMS WILL HELP YOU IMPROVE YOUR RECEIVING
BUT HOW MANY OF THEM WILL REALLY HELP YOUR SENDING? . . .

THIS ONE WILL

AND IT INCLUDES A PANASONIC PORTABLE CASSETTE RECORDER !

- Practice receiving with pre-recorded cassettes
- Practice sending with the built in code practice oscillator
- By recording your own sending, you will be able to spot flaws and errors that would ordinarily be overlooked
- When it is not being used for code practice, the recorder may still be used around the shack and for general entertainment purposes
- The system comes complete with a 1 hour pre-recorded cassette (specify speed), a 1 hour blank cassette, microphone, earphone, and batteries.



WOODSIDE CS-1 . . . . . .$48.00

Extra pre-recorded cassettes (1 hr) specify 8, 16, or 25 wpm . . $5.50

connected? The answer came on me like a flash flood.

Buick had done us Riviera owners a big favor: to justify increased costs, they gave us all a big fat juicy electric fuel pump. Now all I had to do is find that stupid pump – the one remaining electrical apparatus I hadn't checked out. In years gone by, the purchaser of a car would receive a book that would tell the grease points, wear points, ignition points, etc.; so, easing my hand into the glove compartment (it is so small you have to *slide* your hand in), I grabbed my instruction book with the tips of my fingers and slowly pulled the book out so as not to tear off the top skin of my hand. I scanned the book. No index, and no mention of a fuel pump, either electrical or vacuum.

I called all my engineer friends over to the house for beer and help, and we all started to slowly circle the car, each trying to come up with a solution. Where was that furshlugginer pump? Here we were, six engineers – and no one could even suggest where we might find the fuel pump. Finally, someone suggested it might be under the trunk floor – only as a desperation move, we looked. And sure enough, there it was. . . a black Bakelite cap with a blue and a brown wire coming from it and heading in the general direction of the front of the car.

Back down into the shack we went to make up a low-impedance coil, but here we had one problem. By this time, the brew had us slightly staggering and no one could read the grid dip meters. But after a couple of hours we did manage to make up a coil. After it was installed, I started the engine and turned the Gooneybox on . . . Voila! It worked, and I immediately made a contact with a ham about 30 miles away. No more hash!

But where are the 6 meter hams? The band is dead here now!

KEEP 'EM COOL IN "KPO CANS"

Douglas Byrne G3KPO
Jersey House
Eye, Peterborough, England

Tubes get too hot for comfort, burn themselves up aplenty . . . what to do? Keep 'em cool, boy, keep 'em cool!

Easier said than done, for while tubes get smaller, nobody has yet succeeded in miniaturizing the watt. Of course, you can use a blower, but that brings with it problems of vibration and noise, both mechanical and electrical.

So let's see if we can't get that unwanted heat away much more efficiently by the normal method of radiation and convection—with the aid of flappy tailfins! No noise, nothing to wear out, and best of all—no cost . . . here's how.

Heat is extracted from the tube by a special heat-dissipating shield made up of a series of individual tin plates shaped as shown in **Fig. 1**. End D has direct thermal contact with the tube body, extracting heat by conduction, transferring it to end E, where the heat is removed by radiation and convection of the circulating air.

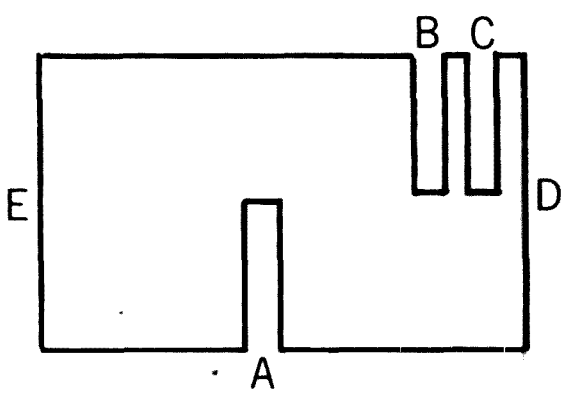

Fig. 1. An individual plate.

To make, you need to cut a half-dozen or so small sheets of fairly flexible sheet metal (2½ x 4 in. will be about the right size for the usual PA tube).

Snip a slot in each plate as at A in Fig. 1, and a few more as at B and C—cut each slot sufficiently wide and deep for A of one plate to slide easily in B or C of the next, the bottom and tops being level with each other.

To assemble the thing, slide slot A of one plate into slot B or C of another. Continue until you have a circle of plates, with an opening in the center for the tube and the flappy tailfins sticking out all around.

Paint all fins flat black. Black has a heat-absorption characteristic and will enhance the overall efficiency of your dissipator.

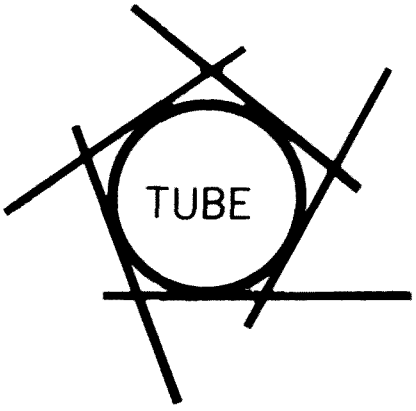

Fig. 2. Plan view of complete shield on tube.

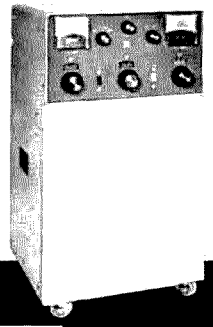
Now try it on for size. If slightly out, select slots B of C as appropriate. If much too large, cut a new slot. Slide over tube and bend or cut tailfins to avoid nearby components.

A secondary benefit of the shield is that it will reduce direct radiation of heat onto such things as vfo coils and electrolytic capacitors, where it is definitely NOT wanted.



A good point to remember is that not all circuits will be able to tolerate the tube capacitance introduced by the shield. Some experimentation is warranted in most cases. Retuning will be required in virtually every case.

TOWARDS AN IDEAL SOLID-STATE I-F FOR AMATEURS

PART 2 I-F FILTER, CONVERTER, AVC

. . . Breadboarding the complete IC system.

William Hoisington K1CLL
Far Over Farm
Peterborough NH 03458

This second part of a two-article series on a reasonable cost, portable "ideal" i-f for the amateur homebrewer describes the design method and working breadboard model of the 1.65 MHz to 135 kHz converter module, a 135 kHz i-f filter which really cuts the mustard, an avc module for use with the Motorola HEP 590 IC i-f amplifier, and the results when using the whole i-f system. If you like plenty of lows when listening on the bands, this is the unit for you; the bandwidth is between 3 and 4 kHz, which is cutting it pretty close for good voice quality. Of course, when the going gets real tough, you don't care about quality, but you do care plenty about understanding what your contact says. That's when a narrow bandwidth really helps.

The possibilities for the homebrewer with this double-frequency i-f seem quite interesting; indeed, I'm anxious to get one packaged for myself, along with a tunable packaged 10 meter front end for use with VHF and UHF converters.

Overall System

Figure 1 shows the block diagram of the complete triple-conversion portable receiver. Previous articles have described detailed construction of various portions of this system. This section is concerned with the 1.65 MHz to 135 kHz converter, the avc module, and the 135 kHz filter.

On the subject of mixers, be sure to read the "trouble" section, where it shows what happens when you put a high Q coil in the collector circuit of a lively mixer and leave the emitter only partly tied to ground. In this condition, you're in grave danger of very strong oscillation on 1.65 MHz (if that is the frequency of the output circuit).

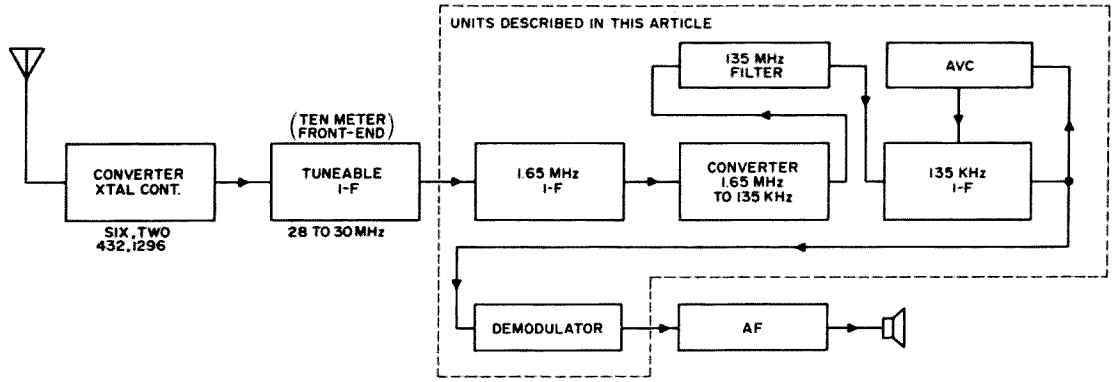

Fig. 1. Block diagram, ideal i-f system.

Instead of the first crystal-controlled converter followed by the tunable 10 meter front end, you can use a tunable 6 meter job if you wish, resulting in a double-conversion receiver. You can even use it that way on 2m, but tuning gets pretty touchy then. The crystal oscillator in the VHF–UHF converters relegates the tuning business further down the line to the 28 MHz region, where it can be done in a reasonable fashion.

Once the i-f system is packaged and installed in a little carrying rack along with the desired converter and companion solid-state transmitter, it should make an extremely interesting and useful addition to portable amateur equipment –and at reasonable cost for the homebrewer.

Mixer

In the past I have described several 1.65 MHz mixers, but this is the first using ready-made coils that you can buy on the market; that is, these are the Miller series, described in detail in the first part of this article. Of course, you do have to add an extra winding or so, but the coil form, adjustable center threaded core, tuned winding, outer powdered-iron core, and the aluminum case are all there.

Various types of oscillator injections were tried, and the one shown in Fig. 2 is the result. It uses straight link coupling from the oscillator inductor to the mixer base coil, and has the nice feature that the amount of coupling is easily adjusted for the best

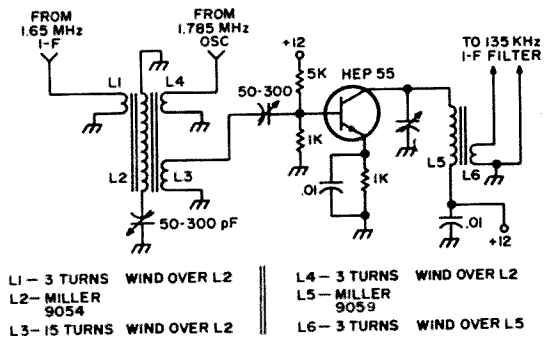

Fig. 2. 1.65 MHz to 135 kHz converter mixer detail.

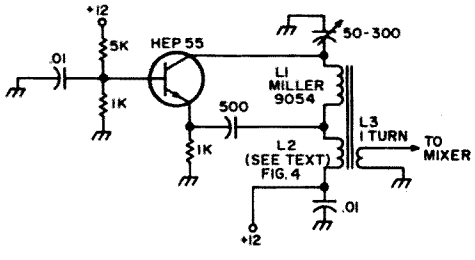
effect. This is useful because if you undercouple you lose gain, and if you overcouple you can get frequency "pulling"; unwanted



harmonic power rises also. You will notice several windings of only 3 turns or so, which is a small number at an intermediate frequency. This is possible because of the powdered-iron cup core used, which increases the magnetic coupling and the Q of the coils. Figure 2 shows the mixer circuit using the Miller coils.

Here's how it works: Signal energy from the 1.65 MHz i-f module comes in on L1 and is transferred selectively to L2, and from there to L3, which is matched to the base input of Q1. Oscillator energy at 1.785 MHz is supplied also to Q1 via L4, and the two signals are mixed, or beat, in Q1, to furnish a collector output on 135 kHz.

The collector circuit is tuned to 135 kHz with a Miller 9054 inductor and a mica compression trimmer of 100 to 500 pF. A link of 3 turns is wound on top of the 9054 winding to couple energy to the filter. The base and the emitter are treated in the usual fashion for dc bias, with the emitter heavily bypassed to ground, which effectively eliminates self-oscillation.

1.785 MHz Oscillator

The basic circuit of this oscillator has not been changed from that described in the first article, but this time it uses coils that are readily available. The Miller 9054 unit works fine with the addition of only 6 turns of wire to create an emitter feedback tap, as in Fig. 3, and a pickup link to transfer the needed energy over to the mixer.

L1 = Miller, 9054
L2 = Add-on winding, see text and Fig. 4.
L3 = 1 turn.

Fig. 3. Converter, local oscillator, 1.785 MHz.

How to do it. Remove the aluminum can from the Miller 9054 coil by bending back the little tabs holding it in place, and make sure that the outer cup core stays in place inside the can. Figure 4 shows the oscillator winding details. You *must* get the direction

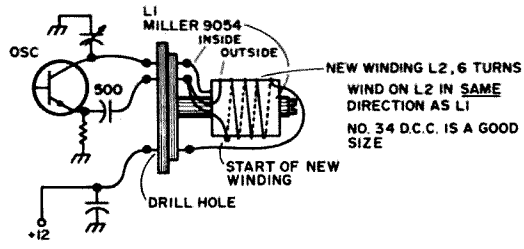


Fig. 4. Oscillator coil detail, 1.785 MHz.

of the feedback winding right or it will not oscillate. Find the direction of the winding making up the original 9054 by looking for the wire coming off the outside and going to one of the two terminals. Then wind on an additional 6 turns in the same direction without changing L1. Figure 4 should show you exactly how this is done. Join the start of L2 to the outer end of L1 at the pin. This point will now become the emitter tap connection as shown in Fig. 3. Bring out the finish of L2 and connect it to the B+, bypassed by C3.

Wind on one turn for L3 on top of L1 and L2 (a little coil dope helps hold them on). I use coil wax for easy changing, due to my experimental work, but coil dope cement is all right once the circuit is working correctly.

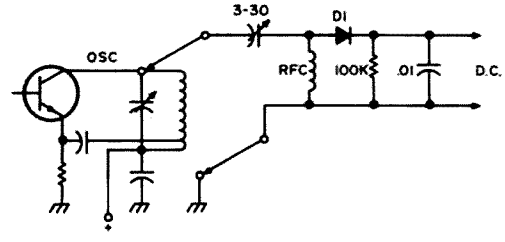

Fig. 5. Diode rf tester.

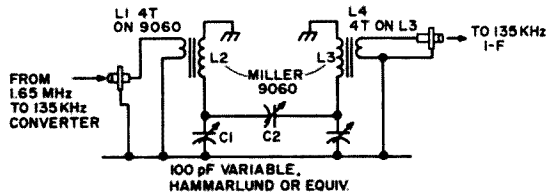
And that's it. You can clip on an rf detector as shown in Fig. 5 for a check on power and frequency. Use an absorption wavemeter or a dipper in the diode position for this test to find the fundamental. Then you can trim up to an exact spot with your receiver.

Use the least amount of power needed to drive the mixer. This will cut down on 1.785 MHz harmonics and "birdies" from getting into the front end of your complete receiver. The value of shielding cannot be overemphasized. Keep any and all rf out of the battery leads, and keep closed-in cable connections to your beam antenna lead.



The best things for elimination of birdies can thus be listed as follows:

- Reduce oscillator power.
- Carefully shield the oscillator and mixer, and filter the battery leads.
- Shield the front end from nearby pickup.

Note that the birdies are 1.785 MHz harmonics and are not i-f leakage, which is pickup of signals on 1.65 MHz. I-f leakage is much more troublesome up front in a receiver, such as on 10 meters, between the 28 MHz tuner and the VHF or UHF converter. In times past I've been startled to hear a W9 calling CQ on 2m, only to find he was on 29 MHz. Plenty of VHF converter output swamps such pickup, and good cabling and front-end shielding help to minimize that type of leakage.

Do-It-Yourself-Filter

As mentioned in the diode section (later) on demodulation, the more tests I make, the more I like the diode across the entire inductance; however, the selectivity suffers a little as a result. Looking for that sometimes-elusive 3-4 kHz bandwidth, I decided to check the operation of a filter. I'm not always particularly impressed with the way some designers use filters. They have a tendency to use just one filter and a lot of amplification along with it, and it doesn't always sound right in operation. So this one was started with plenty of reservations; but after several days of trial and retrial it turned out to be a real goodie. That is, when used in *conjunction with* three other other tuned circuits as well as on 135 kHz. Figure 6 shows the circuit which is a simple "top-coupled" two section job. There are several methods of coupling filter sections, such as link, mutual induction, and magnetic (wound on the same core but spaced). The one shown worked out best and is fairly easy to adjust, with one caution: With a given number of link-coupling turns, maximum transfer of energy may be 10 dB or so down, even with the best adjustment of C. It is a

L1 = 4 turns wound on 9060
L2 = Miller 9060
L3 = Miller 9060
L4 = 4 turns wound on L3

Fig. 6. 135 kHz filter.

combination of the proper number of link-coupling turns (L1 and L4) that produce the happy result of low transfer loss and minimum usable bandwidth.

Theoretical design of filters is a very complicated affair mathematically, with no place in this article. Just make it as shown in Fig. 6 and it will do fine. The entire i-f is already too sharp for a hi-fi AM tuner right now, and does cut the highs noticeably. You could add another filter with possibly another HEP 590 in between but then you might not be able to use it on AM voice.

This filter, in combination with the three other tuned circuits, has been put to use here for several days, changing back and forth between 10 meters, the BC band, and the signal generator. This BC band can be quite informative when used with the signal generator and the amateur bands, because you do want to be able to understand the other party to a QSO even though you're looking for a lot of selectivity. When you have 8 to 10 kHz of flat-top bandwidth, you can do pretty well on the clear channel stations. This clear channel business concerns the FCC's frequency allocations and does not take into account the ideas of Canadians, Mexicans, and Cuban broadcasters, to mention a few. The best thing to do for this test is to check your location and the frequency allocations for a strong local and a not-too-distant next-channel station in the daytime. Incidentally, look out for those BC stations that use *over* 100% modulation. The most powerful one in Massachusetts does just that!

When I check on the signal generator, using the filter, and measure ±1.5-2 kHz for about 6 dB down, I've got a good communications set bandwidth. This shows up on the BC band with definite cutting of highs. Bear in mind we are not talking about a $600 set, which can afford bandwidth switching. This is just a good homebrew filter job that can be put together on your bench for a few dollars, plus more than just a few days.

For best results this unit should be installed in a Minibox, although it also handled well on a copper-clad 5 x 8 in. baseboard. You can also switch the filter in and out, with suitable care, as in Fig. 7.

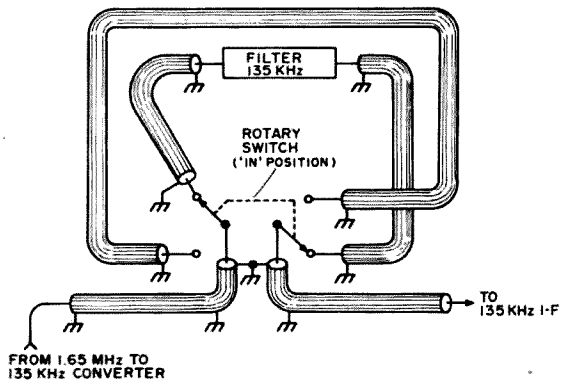


Fig. 7. Bandwidth switch, 135 kHz filter.

Demodulator

I spent lots of time on the demodulator, most of it in conjunction with the bandwidth determination and the filter operation, as these all go together to produce the desired results. The avc system is also tailored to fit in with the demodulator.

Believe it or not, those of you new readers who have yet to experience hours-long DX work on VHF or UHF, the "rushing" sound of the noise made by the receiver itself can be important. It should not be a shrill hiss; it should be a "businesslike" roar, of low tone, and the slightest hint of a signal, even the smallest fraction of a microvolt, should be detectable (by ear as well as on the S-meter). You can see the logic of this when you consider the bandwidth of noise itself. With this i-f system, demodulator, filter, and af, the above is what happens. Of course, you *do* need a low noise front end also and this need automatically becomes greater as you go from 6 to 2 meters, and on up.

Figure 8 shows the best circuit found for the important function of demodulation. With this one you *will* hear that signal, the af

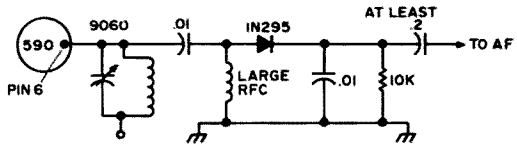

Fig. 8. Best demodulator circuit.

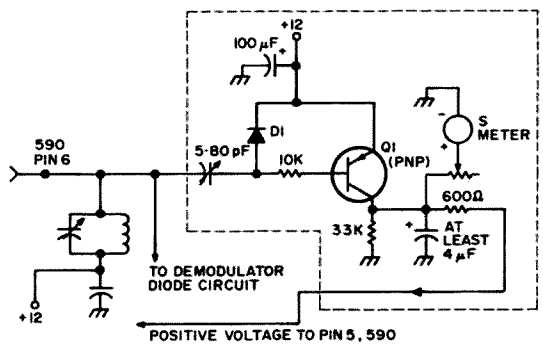
quality will be good, and your chances of enjoying those QSOs will be best.

It should be followed by a good tone control circuit and a good af amplifier such as the Amperex TAA-300, and a good speaker. You need some lows in there to punch through the QRN.

AVC Circuit

The use of the Motorola HEP 590 as an i-f amplifier results in considerable advantage, but it also changes the avc requirements, as you will see.

Referring to Fig. 9, pin 5 of the HEP 590



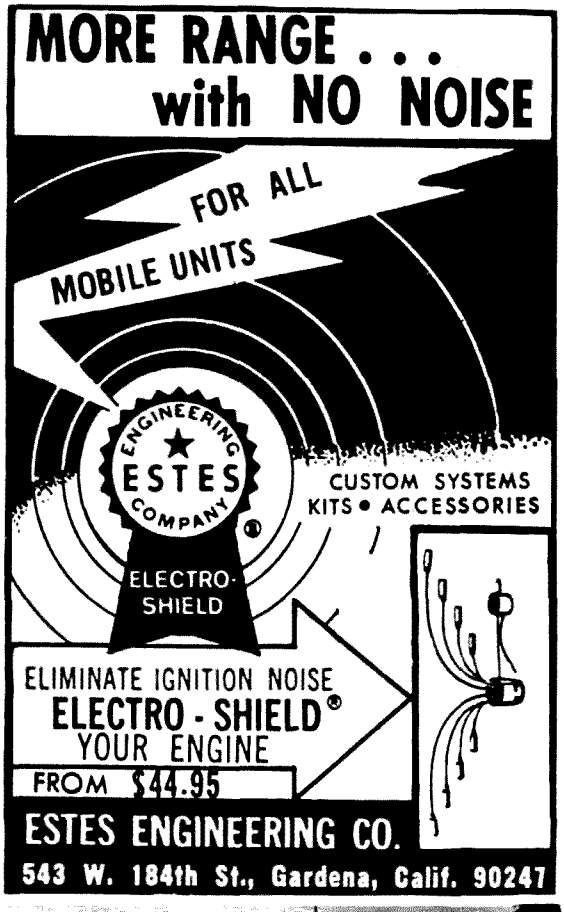


Fig. 9. AVC module.

is the avc connection. When pin 5 has 6V or more of positive voltage, the current of Q1 is shunted through Q3, and taken away from Q2 which reduces the gain of the entire circuit. The big advantage with the IC is that avc can be applied to the last i-f stage, which is also the same stage that is driving the avc system. With a single transistor amplifier stage, this is not normally recommended, but with the HEP 590 it works fine. Another advantage is that you now have places to install an S-meter that reads forward. This is

CAMP ALBERT BUTLER INVITES
HAM RADIO ENHUSIASTS OF ALL AGES
TO TRY FOR YOUR
GENERAL CLASS TICKET

THIS SUMMER! OUR 11TH SEASON

STUDY INSTRUCTION LEADING to GENERAL ADVANCE and AMATEUR EXTRA LICENSE

This co-ed Amateur Radio Camp, Y.M.C.A. owned and operated, can accommodate 60 campers. There is no age limit. We have had campers from 7 through 74 years of age. It is very helpful if you can copy 5 wpm or have a Novice or Technician ticket, but it is not necessary. Time is divided between radio classes in code and theory and the usual camp activities, such as swimming, archery, riflery, hiking, etc. Golf privileges are included at the beautiful New River Country Club course.
Entire staff consists of licensed hams who are instructors in electrical engineering in some of our finest colleges and universities. Camp opens August 1 and closes August 15th. Tuition of $200 includes all camp expenses: room, meals, notebooks, textbooks, and insurance. Send for our brochure.

C. L. Peters, K4DNJ

across the avc amplifier collector resistor (Fig. 9).

Figure 9 shows the final circuit which holds the rectified dc voltage down to less than 1V—even on those Texas kilowatts. A *PNP* transistor is used in an "upside-down" fashion as the avc amplifier. An advantage of the use of an avc amplifier is that very little of the i-f energy is needed to operate the avc system, and no noise at all is contributed by it to the signals.

When testing this out on a signal, with the avc module removed from the IC, the effect of connecting or disconnecting C1 from the i-f was hardly noticeable. I may be a fanatic on conserving demodulator power and quality, but it sure pays off when listening to those DX UHF stations!

When testing this out on a signal, with the avc module removed from the IC, the effect of connecting or disconnecting C1 from the i-f was hardly noticeable. I may be a fanatic on conserving demodulator power and quality but it sure pays off when listening to those DX UHF stations!

How it works. Referring to Fig. 9, a small portion of the 135 kHz i-f energy is taken off the IC output inductor through the trimmer C1 and fed to diode D1. Capacitor C1 is a very handy place to adjust the amount of avc action. With a meter checking the dc output of the demodulator, backing off on C1 drops the avc output and raises the diode voltage to a point where D2 overloads. Increasing C1 raises the avc output and drops the voltage on D2 to less than 1V on the loudest signals. You can set this to suit your own fancy.

The i-f voltage on D1 causes negative voltage to appear at the base of Q1 (a PNP connected upside-down), which then conducts, driving the collector towards the +12V. This positive output is filtered by C3 and applied to pin 5 of the IC amplifier where, as soon as the 6V level is reached, it begins to cut down on the gain of the HEP 590. On a very strong signal, like a W5 on 10m with an ordinary band opening, this voltage may reach plus 7½V or so. It is perfectly possible to apply the avc voltage to the HEP 590 used in the 1.65 MHz i-f also, but this is taken up later, when the whole

system gets packaged into its 99% "ideal" form, in Miniboxes.

Don't be worried about the upside-down PNP. This is a usual practice nowadays. Just "stand" on the +12V bus as though it were the ground, along with the emitter, and look at the ground as though it were the battery voltage for the collector. It works!

Complete System Tuneup and Operation

This is where you can really take it on the chin as you first turn the entire rig on, with unbelievable sounds coming from the speaker. Too much gain, birdies, low-frequency burble, high-frequency oscillations, broad-tuning squeals, and assorted tunable hisses are some of the things that can assault your ears when you connect an antenna, the 10 meter front end, the first i-f, the second converter, the filter, the second i-f, demodulator, af, and speaker—and switch on the battery. (The overall circuit, incidentally, is shown in Fig. 10.)

Table I. Coils for "ideal" i-f system.

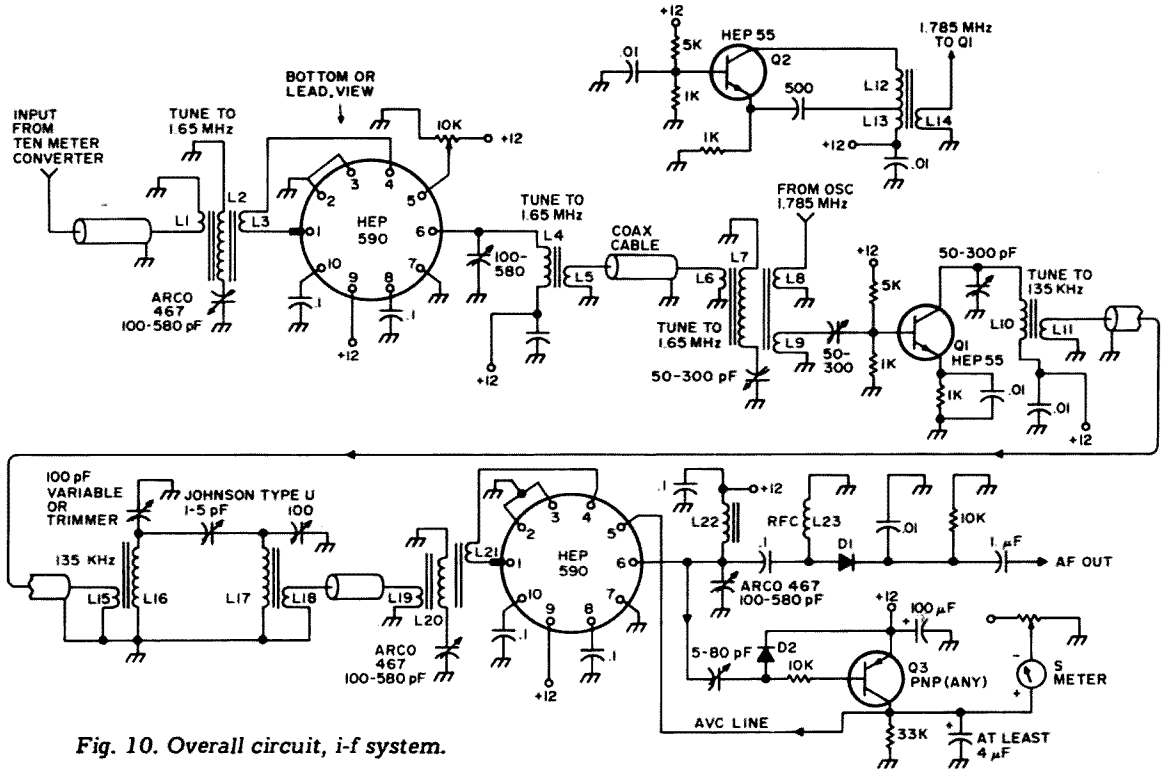

Fig. 10. Overall circuit, i-f system.

In commercial receivers you often see items such as a 300Ω resistor in series with the mixer collector, going to the i-f output transformer, or a large bypass capacitor to ground on a mixer emitter which at the same time is supposed to receive oscillator injection. It does apparently, but only in spite of all known electrical laws! Such fixes can be considered legitimate in that they do allow the system to operate in a satisfactory manner, but in my work I feel that the readers deserve to be told the truth—if it can

be found! It is not always easy to dig down to the basic troubles, though—especially in cases like birdies in the front end from a second local oscillator (or third, when triple conversion is used). It also takes space because when your breadboards are spread out over two benches (see block diagram, Fig. 1) your i-f, af, and speaker wires can sometimes radiate just enough spurious to get back into the antenna wires or front end, with high gain and loud signals—that is, if shielding, closed connectors, and coax cables are not used. A beam, or at the very least a coax-connected antenna outside the shack, is very useful.

Mixers in particular are always suspect for my money. I have recently changed from my favorite mixer circuit over to one in which the mixer emitter is firmly tied down to the ground plane, rf-wise. This whole system performed in fine shape as soon as the mixers received the above-outlined treatment and avc was applied. The work on the demodulation proved especially valuable, allowing plenty of good i-f voltage to be handled by the diode. This in turn makes for good avc action, which has been detailed in the avc section.

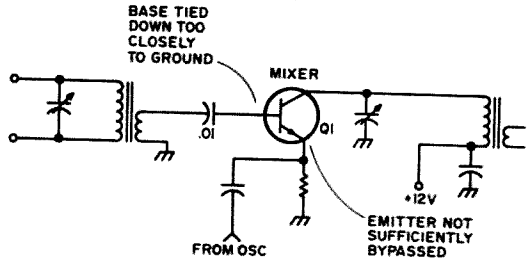
You can also see that packaging of each unit, removal of rf and i-f from the battery wires, and proper interconnections can be quite important. The use of a shielded cable going to at least a two-element beam outside the shack is recommended.

You *do* want a powerful, selective, portable receiver, don't you? One that can be used on 6 or 2 meters or the UHF bands? And in a nice little carrying rack with a companion transmitter? With quite a lot more work to come in the packaging bit, we hope to finally provide you with the plans for such an "ideal" rig, of reasonable size and cost, for use anywhere.

Trouble Department

You might think a mixer would be the last item in a receiver to develop real trouble. After all, it is supposed to just sit there, and is not supposed to oscillate or amplify, although some of them do have quite a lot of conversion gain. What would you say about one that oscillated about 5V worth all by itself?. . .cut off the local-oscillator drive, remove any input and still it oscillates? Well, it happened here and it could happen to you. So here I tell it like it is and I hope it will help you to avoid at least that trouble. It cost me days and a burned out HEP 590 too.

Figure 11 shows the circuit that did it. DO NOT USE IT! It so happens that to make an oscillator, you ground the base, put a tuned circuit in the collector, and lift the



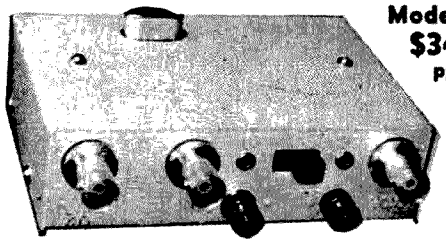


Fig. 11. Trouble-prone mixer circuit. (Do not use.)

emitter off *ground*. See the resemblance? In that mixer the emitter can be considered to be grounded through C2, but it is *not* a *positive* ground. Also, the base is not supposed to be grounded, but there is a very short low-impedance path through C1 and L1, or the base input tap on the rf collector coil. Well, to cut the sad story short, it *did* oscillate. . .like mad! So the circuit shown in the mixer section, Fig. 2, was installed and so far *this* mixer has not oscillated since then. Period.

Results

The finished system was hooked up as shown in the block diagram, Fig. 1, with my faithful old 100 ft wire attached to the 10 meter front end. Being early in the morning, the first station on the dial was a ZS in South Africa, pushing the S-meter around in lively fashion, soon followed by lots of others over there. A little later W5s came booming in to provide checks on the avc section with extra-loud signals. Some of these latter produced nearly 10V of demodulator diode output with the avc off. This overloads it, of course, and it is not used in this condition. With the avc connected it held nicely to 1V or lower, adjustable by the 5-8 pF avc coupling capacitor. Manual control is applied to pin 5 of the 1.65 MHz IC amplifier, as indicated in

THE BEST
2 METER
CONVERTER

Model 407
$34.95
ppd.

144-146 MHz in, 28-30 MHz out
or 146-148 MHz with a second crystal

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of hundreds of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced? Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait? Then send us a postal money order for $34.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

JUST OUT! Our New Equipment Catalog.

the first part of this article, to regulate the overall sensitivity and the amount of receiver noise. The results of using an excellent demodulator, the Amperex TAA-300 "baby hi-fi" amplifier, and a good speaker now showed up in a pleasing fashion. Advancing the af gain as for use in mobile work or in a large noisy room, etc. did *not* result in tinny audio or distortion, but produced good quality audio which was a pleasure to the ears.

The avc swallowed up 90% of the QSB, even 100% of everything that could reasonably be called Q5. As mentioned in the avc section, the small trimmer coupling capacitor bringing i-f energy over to the avc module provides excellent adjustable regulation of the amount of avc you may prefer.

The use of a good dial in the tunable i-f on 10 meters is imperative for an i-f of this bandwidth. The Miller MD-4 two-speed dial does a good job in that unit.

If you want to "steal a march" on my work here, install a bandwidth switch in front of the filter to cut it in or out. Figure 7 shows this unit, but mind you, I haven't installed it yet, so you're on your own. I have plugged and unplugged the filter though, many times, so I know what will happen if you beat me to it. There is an increase in bandwidth when you cut the filter out. This is good for non-DX contacts and locals. For real DX, switch to the 3–4 kHz bandwidth position, which cuts it down to the minimum noise condition.

Conclusion

Design methods, breadboard circuits, overall tests, and results have been detailed for you, trending well on the way towards an "ideal" battery-operated i-f system with low image and high selectivity, which, when packaged, will be a very useful piece of equipment for the active VHF–UHF amateur.

This will soon be matched up with the packaged, single-dial, three-gang tuned 10 meter i-f for use with any VHF–UHF converter, homebrew or store-bought. You will then have an excellent, portable, solid-state receiver that cannot be bought ready-made on the market today.

epoxies for electronics

Elliot S. Kanter W9KXJ
3242 W. Hollywood Ave.
Chicago IL 60645

With the wealth of new materials and devices available to the ham today, it seems a shame to keep on building with worn out and antiquated methods. I am speaking of soldering, a process that has changed little since the days of heating a soldering iron over an open flame and then melting wire solder. This progressed to electrically heated irons or guns, but the basic principle remained the same: heat the solder and the terminal.

Until recently this was about all we could use and we tried to make the best of it. Heatsinks had to be used to protect our semiconductors, and of course, we had to be sure we didn't overheat the PC board and lift a conductor.

Well, there *is* a way to get around the problems of cold solder joints and heat-damaged components: *epoxy*! Not the usual form of epoxy, mind you, but an altogether different form—one which is electrically conductive, that can be cured at room temperature. I dashed off a line to Emerson & Cuming in Canton, Mass., and received a wealth of information on the world of epoxies. I learned that there are epoxies which are thermally conductive, yet still electrical insulators, and that a product called Eccobond Solder 72C was the IC manufacturer's answer to the solder of yesterday.

I sent away for some of this "solder" and followed the simple mixing instructions. A test circuit was put together using the liquid solder as a conductor between a battery and a small lamp. It worked like a copper wire, and during the cure period could be moved or removed with ease. Ohmmeter checks showed that it has low resistance and remains stable regardless of the applied voltage.

Next, I tried to solder dissimilar metals together (a copper wire to an aluminum chassis) and found it would not only provide a solid electrical bond, but had good mechanical properties as well. A friend borrowed some and proceeded to wire his new transceiver using the epoxy solder in place of regular solder. His report: no cold solder joints, no heatsinks needed, and—best of all—no heat-damaged components.

The epoxy solder in one form or another has found acceptance with many manufacturers of electronic equipment since it allows good reliable connections by unskilled personnel and in many cases does away with heatsinks.

Looking further into the catalog and spec sheets, I discovered thermally conductive epoxies which allow you to use the chassis as a heatsink. All you have to do is squirt a glob on the chassis and press the transistor into it. The epoxy presents a thermally conductive bond which is still an electrically isolated one.

All of the various forms of epoxies are available from the major electronics distributors and may be found in their industrial catalog section. Say goodbye to burned fingers and soldering irons and move up to conductive epoxies. The component packaging specialists did it a long time ago.

FET Preamplifiers FOR VHF FM

Earnest A. Franke WA4WDK/2
108 Matawan Terrace
Matawan NJ 07747

A grounded-gate FET preamplifier for 6 or 2 meters offers high gain, simplicity of construction and ease of tuning.

Many amateurs come to the point where they need an extra preamplifier for wider coverage with their mobile FM operation. I have constructed several field effect transistor amplifiers for 6 and 2 meters which yielded many interesting results. Approximately twice as much gain may be achieved when using a field effect transistor in the grounded-source arrangement as compared with the grounded-gate configuration for the same bandwidth; however, neutralization is almost always required. By using a field effect transistor in the grounded-gate configuration, the amplifier was simple to build, gave adequate gain and bandwidth with a low noise figure and ease of tuning. The low feedthrough capacitance eliminated any need for neutralization. The only tuning after construction is to peak the two tank circuits for resonance. When the preamp is used in mobile operation, the supply voltage may be taken from the car battery.

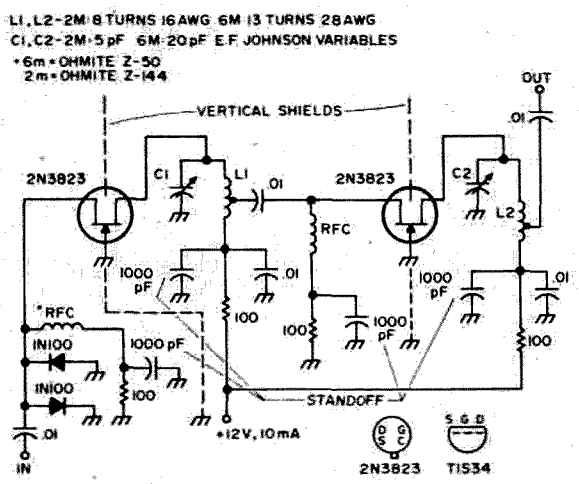

Fig. 1. Cascade preamp circuit, using two grounded-gate FETs, provides plenty of rf gain on 6 or 2 meters. Frequency-sensitive values are listed at the upper left portion of the diagram.

The schematic of Fig. 1 shows the 2N3823 (or TIS 34) field effect transistor cascaded in the common-gate configuration. An input tank circuit was tried and replaced by a simple rf choke to provide the rf input load. The low input impedance

into a grounded-gate configuration tends to broaden or swamp any input tank circuit. The biasing resistor is bypassed to provide the rf ground. Two 1N100 diodes were placed back-to-back at the input connector to prevent possible overload damage. Poor isolation, especially in the antenna relay, could easily destroy the input transistor.

Construction

The amplifier was mounted on a piece of copper-clad printed circuit board. The board, with the copper on but one side, is cut to length and drilled as shown in Fig. 2. The general layout may be increased if parts appear too cramped. Notches must be cut in the vertical shields for the transistor sockets. The boards and component leads

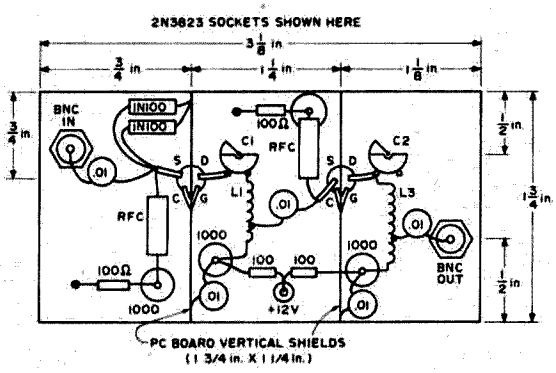

Fig. 2. Sketch shows layout of FET preamp. Note use of shield walls between stages.

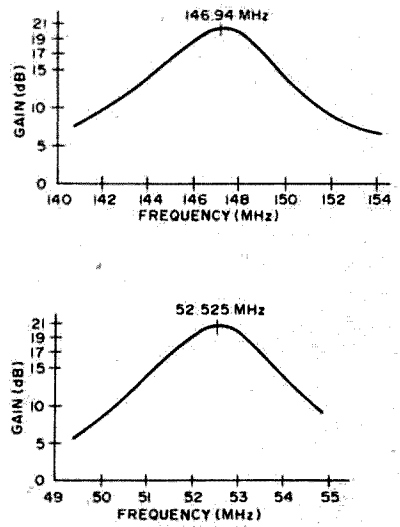

Fig. 3. Gain-bandwidth curves for 2 and 6 meter versions of the FET preamps. Note that gain peaks at about 20 dB in both instances.

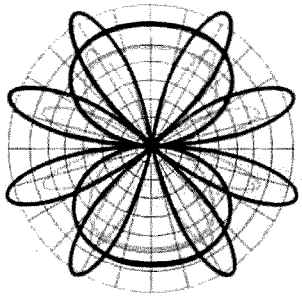
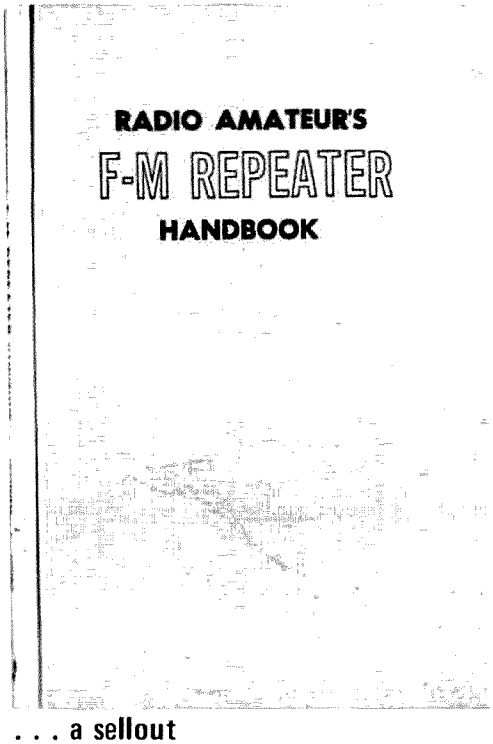
are then cleaned with steel wool to prepare a good soldering surface. After the sockets are mounted, the vertical shields are soldered in place neatly and evenly using a small soldering iron. The standoff button bypass capacitors are soldered firmly to the board. All ground connections are made by directly soldering the part down on the copper.

The 2 meter coils are wound on a ¼ in. diameter rod using 8 turns of 16 AWG enamel-coated copper wire. The coils are spread to ¾ in. long and tapped 2 turns from the supply voltage end. Each 6 meter coil is wound on a 3/8 in. diameter rod using 13 turns of 28 AWG wire, tightly spaced and tapped 2½ turns from the cold end. Care must be taken when soldering the leads to the Johnson capacitors. The stator plates are held in position by solder during manufacture and may fall apart when heated. Maximum capacitance values of 5 pF for 2 meters and 20 pF for 6 meters were chosen for the variables so that they would be in their mid-position at resonance. The output tap may be varied to determine bandwidth and gain. The positions shown here are not critical, but are a compromise for broad bandwidth.



A CU-2101A Minibox is drilled to allow passage of the connectors, sockets, and capacitor shafts. The printed circuit board chassis is then bolted to the Minibox top and labeled with dry transfers or decals.



Performance

With a 12V supply, the preamp draws about 10 mA total current. The two capacitors are tuned to resonance simply by peaking on noise. Figure 3 shows the response characteristics of each preamp. From the results shown, the 2 meter

EDUCATED

The warning or "idiot" lights provided as replacements for dashboard meters in most modern automobiles leave a lot to be desired. Two of their more obvious shortcomings are: (1) they may be illuminated for some time before being noticed, especially on a bright sunny day; or (2) they may burn out without warning, leaving the driver with no warning at all.

Taking a leaf out of the aircraft designers handbook, what is needed is a method of drawing the driver's attention to the lamps as soon as they light, as the malfunction may be serious enough to require immediate attention. The device to be described will cause the illumination of any idiot light to sound an audible alarm. The immediate disadvantage to such a system is that if the light remains on for some time (as, for example, if you have to drive some distance to a service station), the continuous sounding of the alarm could become dangerously distracting. To prevent this, an "override" switch has been incorporated to disable the alarm once it has served its purpose. However the circuit incorporates an automatic reset feature which will reset the alarm once the fault is corrected, so that the next time an idiot light comes on it will sound again without the need for any action on the part of the driver. An added feature of this circuit is that if the fault is not corrected, the alarm will come on next time the car is started: also, each time the car is started, the alarm will sound for a moment as an automatic test of its readiness.

The alarm itself (see Fig. 1) consists of a 12V buzzer, and the reset circuit is composed of a small spdt relay and a momentary-contact spst pushbutton switch. The alarm is connected to the idiot lights through a number of diodes which serve to allow the different light circuits to trigger a single alarm without shorting all the lights together.

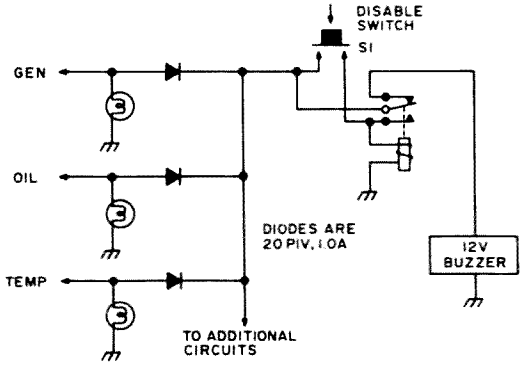

Fig. 1: Circuit diagram of audible "idiot light" alarm.

When one of the idiot lights comes on, the voltage is passed through the appropriate diode, through the relay contacts, and on to the alarm buzzer. When the driver wishes to silence the alarm he pushes the switch; this shorts the normally open relay contacts, and results in the current being diverted from the buzzer to the relay coil. The relay is now energized and holds the contacts closed, leaving the buzzer disconnected. When the fault is repaired and the light goes out, the relay is no longer energized and returns to its normal

IDIOT LIGHTS

D. J. Holford
RR 1, Enfield
Hants County
Nova Scotia, Canada

position, resulting in the buzzer again being connected to the input ready to sound off next time a light is illuminated.

The alarm is not restricted to just those functions provided by the idiot lights, and can warn of any situation capable of being indicated by an electrical signal. For example, it could be used to warn of lights being left on when the ignition is off by use of a suitable circuit.

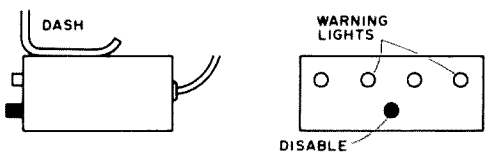

Fig. 2. Suggested mounting method and panel layout.

The diodes and buzzer can be concealed out of sight under the dash (Fig. 2), and the only item which needs to be exposed to view is the pushbutton disable switch; however, I prefer to have an integrated warning panel which saves having to look around to see which light is lit. I duplicated all the normal warning lights, plus others for the additional circuits which can trigger the alarm, and installed them all in a small master warning panel together with the disable switch.

There are a number of suitable locations for such a panel. The easiest and most obvious is under the dash, but items under the dash have a habit of getting in the way of knees. I preferred to make a small panel and install it in the center of the roof above the rear-view mirror, where all I have to do is glance up to see what happened. Another good place for those who have given up smoking is to make a small box which will fit in the ashtray space, and paint it to match the dash. Since there are very few parts, and they can all be miniature, it does not require much space.

I have not included detailed layout and construction plans as the design can be easily customized to your own car and personal desires. The circuits will all be basically the same, but the placement of components will vary. Also some may want duplicated lights and a custom warning panel, while others will conceal the buzzer under the dash, and only the switch will show.

Any small 12V spdt relay will do, plus a 12V buzzer, a pushbutton switch, and the required number of diodes. The diodes are not critical as long as they can handle about 1A at 15–20V. There are a multitude of diodes and relays available at low prices so the constructor should have no problem obtaining parts.

Construction and installation can be easily accomplished in one evening, and the result is an impressive and effective addition to any automobile.

If you decide to add the duplicate lights, you can obtain small self-contained 12V pilot lights at the local radio store for a small sum. One final point to remember: The diodes must be insulated from ground, as both sides are carrying 12V.

. . . D. J. Holford ■

BILL HOISINGTON K1CLL

POSTAGE STAMP TRANSMITTER FOR SIX

Honest Injun . . . you can build one in your cigarette lighter!

You can really hide this one, even in the skin of a bear! It's only ¾ x ¾ x 1/8 in., is crystal controlled, puts out up to ¼ watt on 6 meters, and can be used for biological work, survival units, etc. With a 6 in. antenna I've heard it out to 15 miles.

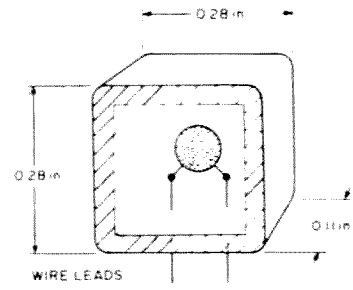
This article describes what can be done on VHF today with off-the-shelf subminiature items. Of course you do have to look hard for some of those shelves – but they *are* available.

The Crystal

As far as I know McCoy is the sole manufacturer of a suitable crystal less than 1/8 in. thick. McCoy has a special glass blower (from the Old Country?) who encloses the tiny little crystals in glass. These gems work, and work extremely well. I've even run 15 mW through the crystal itself and so far no trouble.

Figure 1 shows a sketch with dimensions of this jewel in its Type MM glass package. Of course they don't just give them away, but where else can you get one 110 mils thick? There is still the next size up, the M20, with a "tin can" holder which is 183 mils thick, if you have the room.

I recently acquired two of the MM units and they both worked immediately in the circuit shown in Fig. 2 and have continued to work ever since; so they aren't just pieces of costume jewelry.



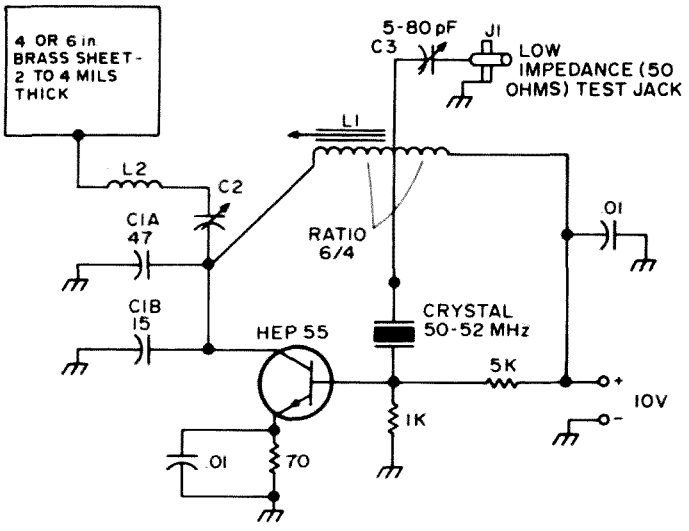


Fig. 1. McCoy's Type MM crystal is an incredibly small element enclosed in a tiny glass package not much larger than a thick-film capacitor chip. Less that 1/8 in. thick, the area of the crystal is about ¼ in. square.

NOTES:

1. "Ground" is the copperclad baseboard plus the battery.
2. J1 should light a No. 48 or 49 pilot light bright.
3. L2 will vary with antenna size.
4. Check final tuning carefully with CIA and CIB compared to a No. 463 Arco mica trimmer, 10 to 180 pF.

Fig. 2. Even though the transmitter packs down in density to about the size of a postage stamp, the circuit is straightforward and without surprises for the builder.

Transistor

Just for fun you might say, I soon tried the Motorola HEP 55, but after checking against others of the same size or smaller, I stayed with it. After all, it's only $1.20, it is plastic, and can easily be filed down to the desired 1/8 in. thickness. The plastic takes up about a third of the overall thickness of these little powerhouses, so you can easily file down to .125, a little on each side. I also checked out several dozen of them for "activity" in the circuit of Fig. 3.

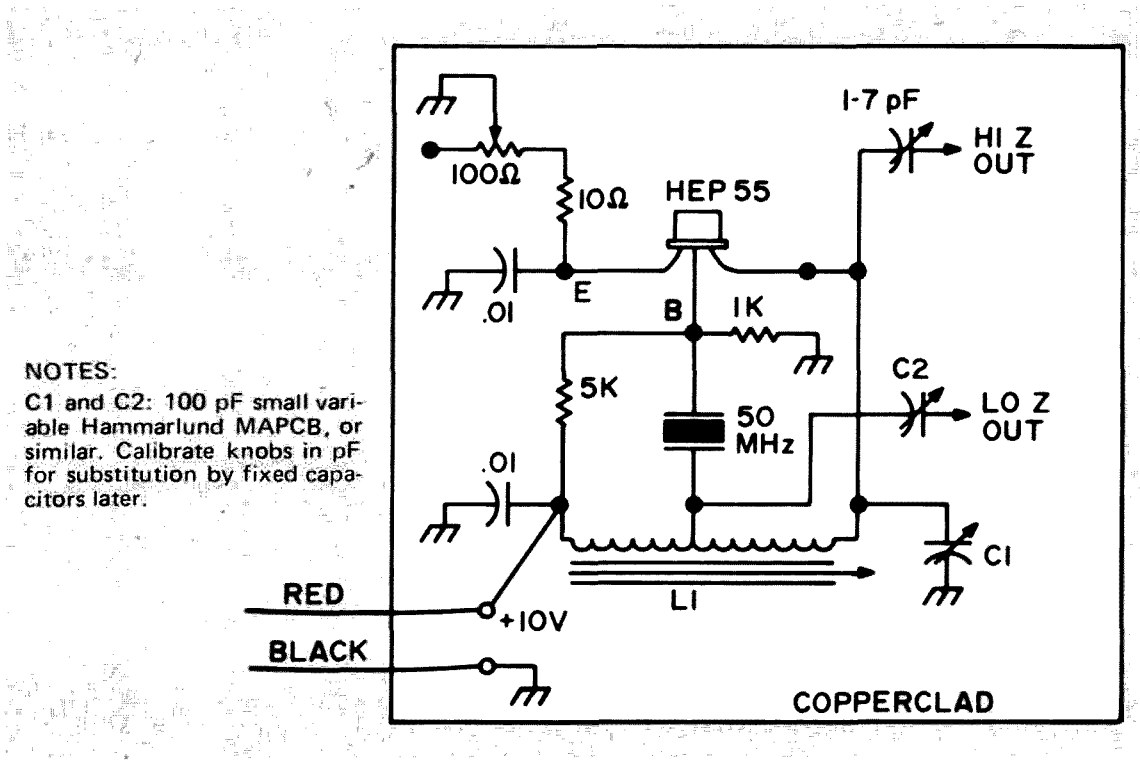

Fig. 3. Breadboarding the transmitter into a test configuration with regular-size component will give you the chance to get the "feel" of the circuit and its capabilities.

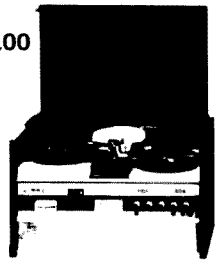
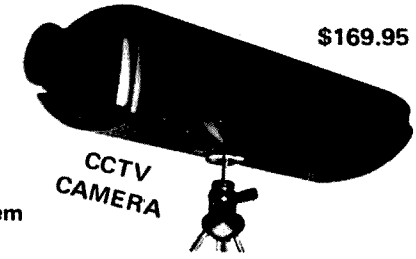
HEAR YE! HEAR YE! COME ONE COME ALL
.... COME TO THE AUCTION!
SATURDAY MAY 16th 9 AM-12 NOON
• RECEIVERS • TRANSMITTERS • ACCESSORIES • NEW ITEMS • TRANSCEIVERS • "A LITTLE OF EVERYTHING" • USED EQUIPMENT
EVANS RADIO, INC.
RTE. 3A, BOW JCT., CONCORD, N. H. 03301 TEL. 603 225-3358

by grading them as *very good*, *good*, and *fair*. I got about 10 in the *very good* category. The rest go fine in i-f circuits, so that settled that question.

I have run 45 mA at 10V for hours at a time, getting over 200 mW output of rf with no trouble of any kind; so there's no need to fear pushing a little if you have a few extra on hand.

Coils





There are two coils, one of which is for loading the 6 in. antenna. Made by Piconics, a suburban Boston company, the coils are tunable and tiny (less than 1/8 in. thick). The tunable feature is one of the major advantages of these coils because, as far as I know, there are no variable capacitors in existence less than 1/8 in. thick.

Just to see what effect the tiny coil size had on the power output, I cut it down and kept cutting down until I reached the size of a piece of spaghetti about 80 mils diameter, wound with 34-gage wire. Even though I squashed it almost flat, the output power remained the same. When the circuit is properly tuned and loaded the coil really doesn't make much difference. Once again, the influence of the matched circuit and the loaded Q! If the proper amount and phase of feedback is there, which it is in this case, the rf output almost burns out a No. 48 bulb.

The circuit tunes broad but correctly and smoothly, and stays exactly on 50 MHz, or 50.4, or on whatever frequency the crystal is ground for. It also stays on the air, which is very important. As usual with any crystal oscillator, load it up to where it does go *off* the air, and then unload it so that it stays *on* the air with whatever battery voltage you may choose to use as the end of the battery life.

Breadboard Test

Use the test jig of Fig. 3 with large variable capacitors for tuning up and checking out the subminiature components *before* you mount and solder them into the tiny "chassis." I found that 15 turns of wire (32 or 34 AWG) with the crystal feedback tapped on at 5 turns from the low end was very good. Ten turns of 26

AWG on a threaded paper form was handy to start with, and sure-fire for use on 6 meters.

If you calibrate the knobs on the variable capacitors you can then substitute fixed values later when you get down to the subminiature size, and do the tuning with the Piconics coil. This tiny wonder, shown in Fig. 4, actually has a core which moves in and out by means of threads in its nylon holder. Don't forget, you've got to tune *something*. It is possible to substitute fixed values of capacitors and make it work, but I'm assuming you've handled enough transmitters to know the value of tuning up. A good Piconics coil for 6 meters is the one labeled B121K713Y1. That's quite a mouthful, but it not only indicates the inductance but the ratio of the tap position as well – just be happy

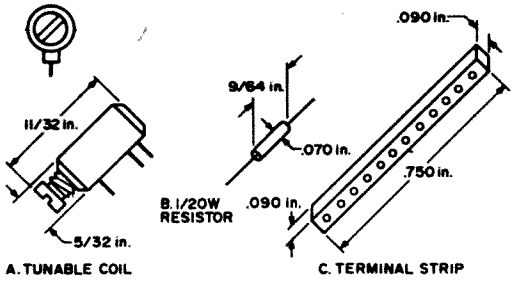

Fig. 4. Layouts and dimension of some of the "micro" components in the postage stamp transmitter.

that someone makes one that's on the shelf ready for you.

Resistors

Sprague Electric, Nashua, N.H., makes good 1/20 watt resistors. They are precise and tiny, and they work. Figure 4 shows dimensions. 'Nuff sed.

Capacitors.

Republic Electric makes capacitors up to the .01 μF value used here. They have a maximum diameter of 60 mils. That's under 1/16 in., in case you haven't been in a machine shop lately. Every one of these skinny cylinders has worked properly. I don't know how they do it but I'm going to find out soon with a visit down into the wilds of Patterson, N.J. to see for myself.

Mounting Strips

I really had to turn on the old imagination for this one. Past readers may recall my frequent use of .021 "common pins,"

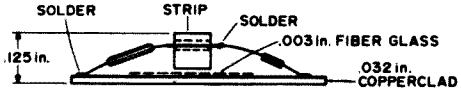

Fig. 5. Side view shows terminal strip utilization and mounting technique.

brass, nickel plated, for terminal strips, hammering them into 20-mil holes in fiber glass strips or linen-base Bakelite. Well, these are too big for this job! So I cut up some of the linen-base Bakelite stuff into square cross-section rods and drilled through the sides of them, as in Fig. 4C.

Figure 5 shows the drilled strips, or "logs," with a small strip of 1½- or 3-mil fiber glass under it for security against ends of components or wires shorting to the base plate, and examples of components used. You can drill as many holes as you have wires or solder two or more wires together on one side of the strip.

Chassis

Figure 6 shows the baseboard cut out to receive the major components, which are the coil, the crystal, and the transistor. As these units are over 100 mils thick they cannot be mounted on top of the baseboard but do very well in the cutouts with coil cement or other types of embedment added later. Although I am showing one example of a circuit with the 1/8 in. thick technique, you can of course use the same method for other circuits. I have gone up to 432 MHz with this type of construction, so various things can be done at the 1/8 in. thickness. After mounting and soldering, you can also use high-temperature coil wax for a test unit which you might want to change later. This can also be used for a "next to final" model.

Batteries

In my quest for a really tiny battery (1/8 in. thick), I found that only two qualified

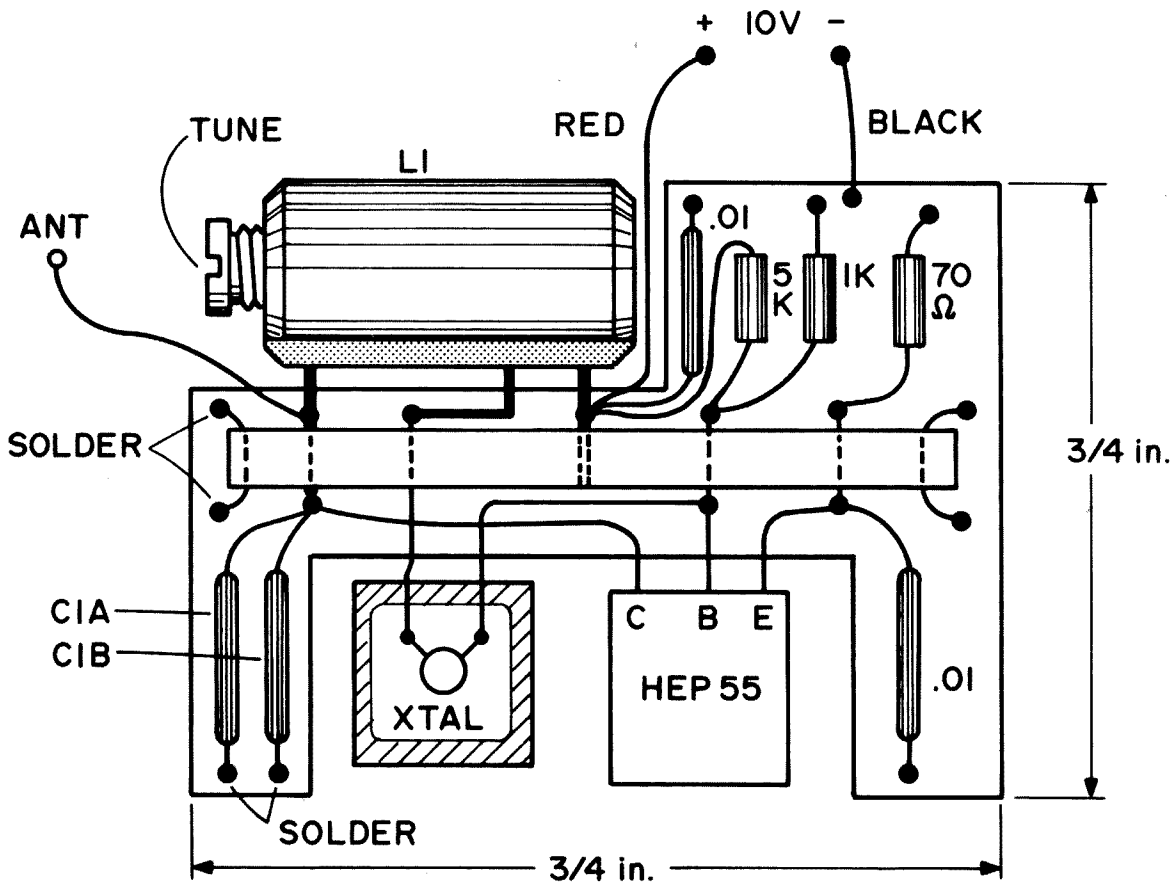

Fig. 6. Blowup top view shows layout of subminiature oscillator. Actual physical size of unit will be 3/4 in. square.

as "desirables," and one of these was ultimately eliminated by testing. The two candidates were the *silver oxide* and the *mercury* types. The dimensions of the smallest is shown in Fig. 7. For up to about 100 mW output, with a battery drain of about 20 mA at 10V, a check was made on the above types. The silver oxide battery lasted 30 minutes and the mercury battery 65 minutes. Of course, these tiny power sources are *not*, absolutely *not*, sold for any such use. In fact, the engineering department heads of the two largest battery companies tend to either raise their voices or hang up the phone, or both, when they find out what you really want out of their little aspirin pill batteries.

There are two immediate solutions: reduce power, or reduce the time on the air. For some uses – such as continuous monitoring with voice or other sound modulation – you have to reduce power for any reasonable life at all. This can be done very simply by using less battery voltage or increasing the resistance of the emitter resistor, or both, and a slight amount of retuning. For some other types of uses, such as biological tracking, hidden transmitter hunts, etc., you can turn the rig on for short periods only; for example, 10 msec out of every second for an increase in battery life of *better* than 100 times. (There is nothing worse for battery life than a constant heavy drain.) This type of automatic keying is, as usual, another story. The tiniest little transistors, the Microtabs by GE, can be used for this service in a multivibrator circuit to drive another one of them in a simple on–off switch type of hookup.

For the battery pack, a 1/16 in. sheet of soft plastic such as PVC (polyvinylchloride) can be used to hold the batteries in a pack of four, six, or eight (or even ten

if you like "high power") as shown in Fig. 7. If you order a large quantity, Mallory will *weld* tabs on each pill-size battery and you can then solder them together to make up a pack. Count on no more than 1.0V per cell, regardless of the drain you may expect, because they will soon enough reach this level, or even lower, unless you operate in a pulse mode.

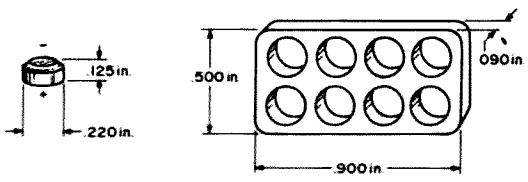

Fig. 7. The tiny battery can be used with other batteries if a holder is constructed from PVC as shown here. (Holder shown accommodates eight batteries.)

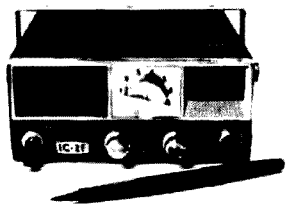
For test operations I did solder leads onto them, much against the advice of the engineering departments of the battery companies. So far, no ill effects, but you have to do this *very* carefully. I used a 25W iron well cleaned and tinned, shined up the battery case first, and then tinned it. A touch of perhaps less than one second does the trick, also using very-small-diameter solder. I am *not advising* this method, just mentioning that I did use it! Also, use flexible subminiature wire such as multiple strands of 34 AWG, for example, with Teflon insulation. These batteries can be purchased where hearing aids are sold and in many radio stores. Naturally, use the largest size you can put into your project. The "aspirin" size will only give a life of 12 mA-hr at something like a 1 mA drain – *not* enough to operate the oscillator. It will run at around 4 mA, though. This power level is easily adjustable by the emitter resistor, as mentioned before. You can generally expect about 50% efficiency for dc input to rf output power with the circuit shown in Fig. 2.

Circuit

When I first made up this design I was looking for a foolproof crystal circuit, one that would not take off on any frequency other than the one marked on the case. The circuit shown achieves this goal; after working with it some time, I find that it can be a very powerful oscillator as well – stable and reliable. In a later 73 article (*Solid-State Power on Six*) you will see it running at over a watt, with up to 500 mW output!

How it works



Referring to Figs. 2 and 3, when the collector is tuned to 50.4 MHz, for example, by C1 and L1, with 10V in, a volt or so on the base, a bypassed resistor from the emitter to ground, and a 50.4 MHz crystal connected between the base and the tap on L1, it *will* oscillate. It's a law of nature! Note that the feedback looks as though it was degenerative, or negative. It only looks that way though, because the crystal reverses the phase of the feedback voltage going to the base. This is a fact of life very difficult for some engineers to swallow but it works! Even the Curies in France in the last century knew that much about peizo-electric crystals.

The result is advantageous. With positive feedback coupling, the oscillator can be quite critical for the right amount of feedback, tuning, and loading. With negative feedback coupling, it will only oscillate when the crystal reverses the phase, which of course occurs only on its proper and marked frequency. Just how many half-waves of sound are standing across the crystal is the concern of the manufacturer, as long as these sound waves inside produce 50 MHz electromagnetic waves on the outside, and vice versa of course.

Crystal Power

I think this is a matter to be decided by usage because, while the makers talk about 2 or 3 mW of power in the crystal circuit, I found that a small pilot bulb in series with a 50 MHz crystal lights up a little on the 1W oscillator. In the CW mode you will not run that much, but with pulsing you may well go over it. About 10 to 12 mW is required in the transistor base–crystal circuit for about 500 mW out at the collector circuit. You can see that the gain of the transistor is important also.

JOIN THE "NOW" MODE.

2 METER FM with the Deluxe Solid State VARITRONICS/INOUE IC-2F

FET front end for low noise! INTEGRATED CIRCUITS used in the AF and IF circuits for greater reliability. ELECTRONIC T/R SWITCHING – no relays. CERAMIC FILTERS in IF circuits for excellent bandpass shaping. ALL SILICON transistors. Rugged, well-designed interior construction with shielded stages to assure stability and prevent spurious interaction. 20 WATTS RF INPUT for 10 watts+ output. TINY – 2¾" x 6¼" x 7¼". Complete with microphone, three position chrome mobile mounting bracket, crystals installed for two channels (Ch. 1, 146.34/146.94; Ch. 2, 146.94/146.94) power connector and plugs, and operation manual. Financing available. Truly, tomorrow's state of the art today!

In the "Good Old Days," a pilot light was regularly installed in series with the crystal. Granted, those were big fat crystals, on 160 meters, etc., while we're talking here about a real skinny one, for 50 MHz. After all, a wave, even if it's a slowpoke one like a sound wave, doesn't go very far if it has to stop after one fifty-millionth of a second. So you can take your choice as to the power you run. You can see that the more lively the transistor, the more power you can run from an oscillator with a given crystal's *rf milliwattage*.

Antenna

The tiny 6 in. antenna's performance was a surprise to me even after half a century in radio. Using the antenna and loading circuit shown in Fig. 8, I left the rig in a house in Jaffrey, N.H. and could still hear it in Francestown, more than 15 miles away. On 6 meters, this is an antenna of about 1/36 wavelength long. You can be surprised or not, as you please. I was. The

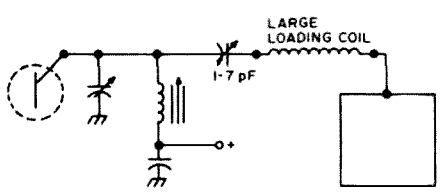

Fig. 8. Although several antennas and loading techniques were tested, the approach shown here proved significantly superior.

only disadvantage of the antenna loading technique shown is that you need close to the right number of turns on L2; other loading techniques may be less critical, but experiments have shown that they are not as efficient when it comes to rf radiation.

Receiver 1

First, you need a diode field strength meter for use at a fixed distance, say a foot or so to start with, in order to tune up and compare radiated power. I soon found that the best setup was another short antenna clipped onto the diode detector's tuned circuit about halfway up the coil (Fig.9). For meter indication at maximum distance, the length of the whip and its contact position along L1 are important.

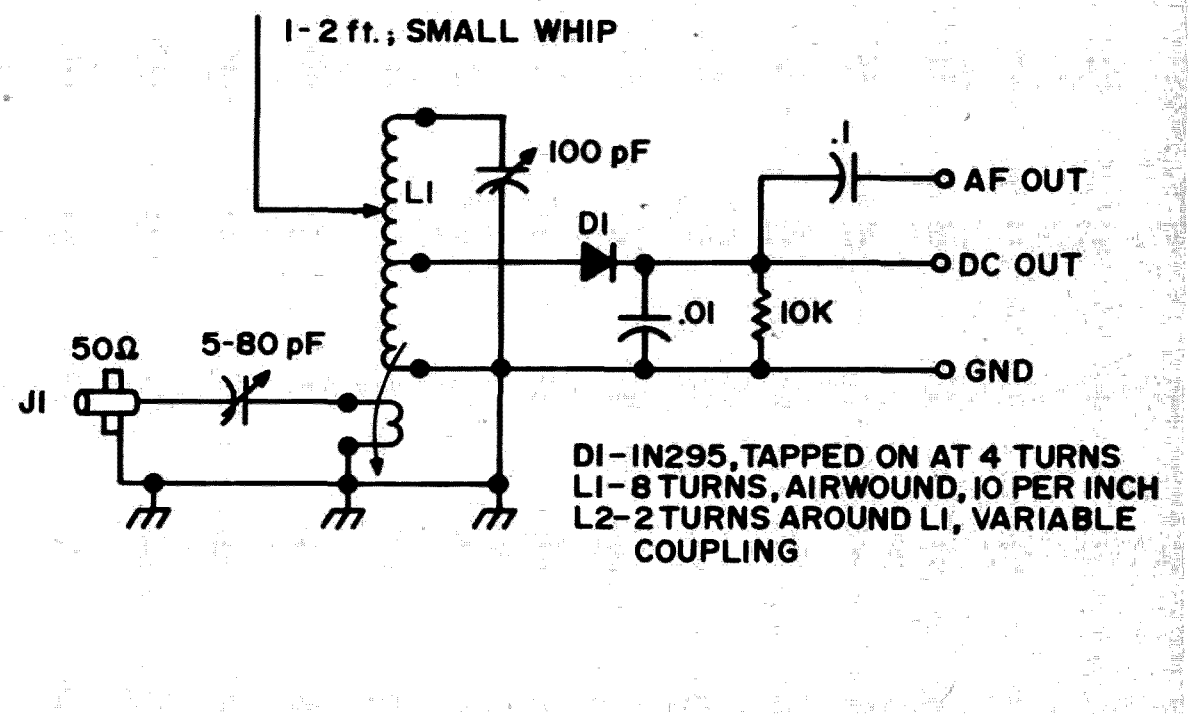

Fig. 9. A diode detector makes a convenient and useful receiver for checking the performance of your postage-stamp transmitter while it's on the bench.

Figure 9 shows the circuit I used, which is also a good frequency meter for checking to see if you *are* on 50 MHz and not on some harmonic. *Never* rely on a high-gain receiver for this basic fact. Use it to check for noise, hum, stability, etc. once the frequency has been determined.

Polarization can also be checked with the diode receiver by using a regular 50 MHz dipole (or beam if you can handle it physically) across the room, or outdoors if needed, with its matched cable plugged into J1 (Fig. 9).

Receiver 2

I put some tone modulation on the rig to identify it because at a distance of 15 miles I wanted to be *sure*; but of course you can use plain CW with a bfo if you like. Either way, the signal comes in great with a regular receiver and beam on 6 meters.

For a particular purpose in mind I did build up a good hand-carried receiver for use with these little rigs. This is a semi-fixed-tuned job with small knobs on the tuning capacitors for test purposes – it tunes over the band in great style. The front end has a 1.7 dB noise figure, which is very useful because you can take it to absolute "hermit" locations, where such performance really *counts*. But, of course, that is a completely different story, and will be published later.

STAFF

Part XVI: RF Power Amplifiers

In the previous installment of this Extra Class study course, we began a discussion of some points of transmitter operation included on the official FCC study list of questions. This time, we'll conclude our look at the subject of transmitter operation.

In the process, we'll examine the following FCC questions:

40. How can the output circuit of a transmitter be adjusted to increase or decrease its coupling to the antenna system?

50. What would happen if the grid-bias supply of a Class C modulated amplifier was suddenly short-circuited?

61. What are some causes of the excessive production of harmonics in rf amplifiers? How can these causes be remedied?

62. What effect does a transmission line which is not properly terminated have on the plate tank circuit of a transmitter?

78. Give some proven methods of harmonic reduction in transmitters.

We'll follow our usual practice, and rather than providing specific answers to these specific questions, rephrase the questions into new queries with broader scope so that the general principles underlying the details can be brought out.

These five questions group into three broad subjects—harmonics, antenna circuit interaction with the transmitter, and effect of losing grid bias.

And as it happens, all three subjects are parts of the general subject "What Goes On In The Final Amplifier?"

Unfortunately, *that* subject is much too broad for us to examine in any detail, so we'll have to strike some medium. We can start by asking "How Can Harmonics Be Controlled?", which will wrap up FCC questions 61 and 78. This will also tie directly into another question, "How Does the Antenna Circuit Affect the Final Stage?", which will take care of FCC questions 40 and 62 among other points. Now we have only the FCC question 50 to cover, and we can get it by asking "What Happens in a Modulated Amplifier?" Actually, a large part of this question was answered in our previous installment, but question 50 is one which can be rather tricky as it has no single specific answer, so it's worth going into again.

By this time, we'll assume that you have been following this course for some time, and we'll assume that you already have a pretty fair idea of what goes to make up the final rf stage of an AM, FM, or CW transmitter. What we have to say here also applies, with some exceptions, to SSB linears—but we've already discussed them as a species apart.

Ready to explore the depths of the harmonic problem? Let's get under way.

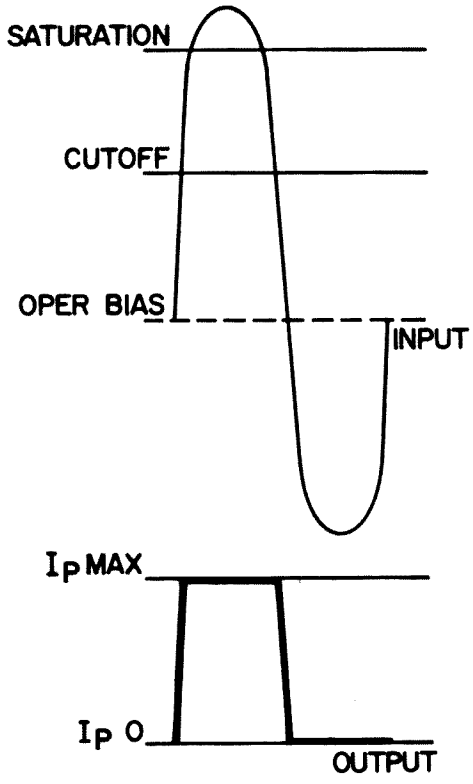

Fig. 1. Class C waveforms.

How Can Harmonics Be Controlled? We have only two avenues of attack in any effort to control harmonics—one is to prevent them from being created in the first place, and the other is to prevent them, once created, from getting out of our transmitters.

It might appear simple, at first, to operate an amplifier in such a manner that no harmonics were generated. And it might actually be simple, if there were any such thing as a *perfect* amplifier. We, however, must get by with imperfect amplifiers and their resulting distortion—and any form of distortion involves the creation of at least a small amount of harmonic signal.

Even if we had perfect amplifiers, the only possible harmonic-free amplifier would be one operating in Class A. This would, in itself, rule out the harmonic-free amplifier for any appreciable power level in transmitters, because Class A amplifiers are only about 25% efficient at best. To produce large amounts of rf energy and stay within our power limits, we must use Class B or Class C circuits.

And by the nature of their operation, Class B and Class C amplifiers are prolific generators of harmonics. The Class C amplifier, in particular, clips off its input signal sharply at the bottom when cutoff level is reached, and equally sharply at the top when the amplifier's saturation point is reached (**Fig. 1**). The result is that only a small pulse from the original input signal gets through the amplifier. Any pulse with sharp corners contains a large amount of harmonic energy; the sharper the corners, the more high-order harmonics are present (the limiting case of this is a perfect square wave, which contains the fundamental and all the odd-order harmonics out to the umpty-umpth).

If we reduce the level of the input signal to avoid saturation, and decrease the grid bias so that cutoff isn't reached quite so rapidly, we can reduce the sharpness of the clipping action. But while we're doing so,

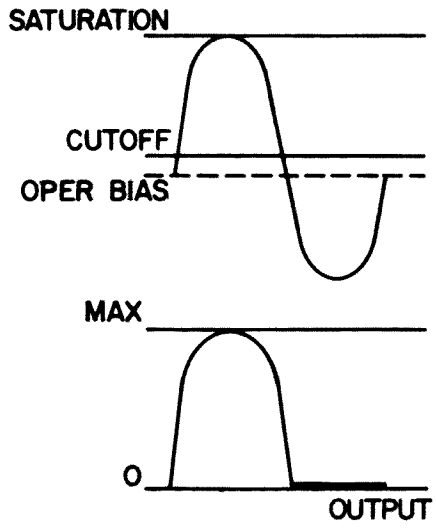

Fig. 2. Class B waveforms.

we're changing the amplifier from Class C to Class B operation (**Fig. 2**) and reducing its efficiency. When we have completely eliminated the saturation-point clipping, and moved the cutoff clipping point down so that we get the positive-going half-cycle of input signal through to the output and lose only the negative-going half-cycle, we have a true Class B operation.

If we keep reducing bias until no clipping at all occurs, we can get rid of much of the harmonic energy—but we will have converted our amplifier to Class A (**Fig. 3**) in the process and our efficiency is virtually gone.

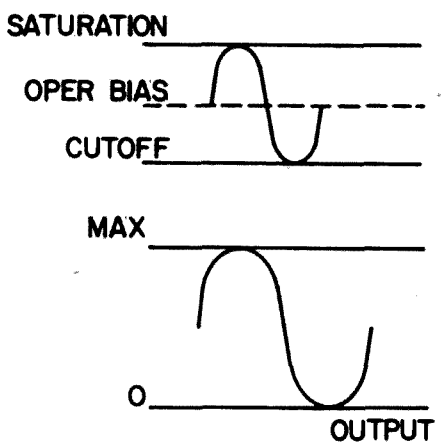

Fig. 3. Class A waveforms.

The point is that the high efficiency of the Class C circuit has its price, and that price is the high percentage of harmonic energy present in the output. In fact, most if not all of the added power in a Class C amp's output (as compared to a similar circuit and input power operating in Class A) is composed of that harmonic energy!

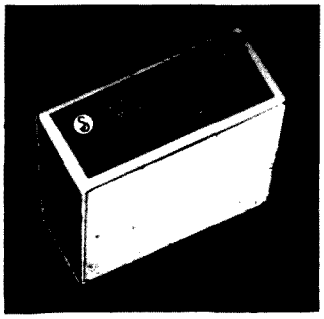
What saves the day for us and makes the Class C circuit practical is the selectivity of the plate tank circuit. Like any other tuned circuit, the plate tank rings readily at its own resonant frequency, and tends to bypass all other frequencies. In the process of bypassing the harmonic energy, it is temporarily stored in either the magnetic or electric field of the tank, and adds to the output power at the fundamental frequency.

When we use the phrase "fundamental frequency" here, we mean the frequency to which the plate tank is tuned, which is not necessarily that of the input signal.

A case in point is the "frequency multiplier" circuit so necessary to VHF and UHF transmitters. This is, in essence, just a Class C amplifier in which the output tank is tuned to some harmonic of the input frequency rather than to the input frequency itself.

The efficiency of the frequency multiplier is low, compared to that of a "straight-through" amplifier, because as the harmonic order rises, the amount of that harmonic present in the plate waveform falls. Thus a two-time multiplier is about half as efficient as a straight-through circuit, a 3-time multiplier about a third, and so forth.

To get the maximum efficiency out of a multiplier, we change its operating conditions just a little from those for a straight-through circuit. The most major change is to increase the grid bias. This increases the clipping action at cutoff, and boosts the harmonic content of the output by making the clipping more sharp.



We can take a trip from this to find ways of reducing the harmonic content of a Class C amplifier's output. Reducing the grid bias to the lowest level that will permit desired operation will help cut down the harmonics, as will trimming grid drive back to the lowest necessary level. And by all means, we should make certain that our plate tank circuits are tuned to the desired frequency. It's not too uncommon for Novices to accidentally tune to the wrong dip, but that's not what we're talking about so much as the possibility of an unwanted additional resonance at or near some high-order harmonic such as the seventh, ninth, or eleventh. Such a resonance can result in a surprising amount of harmonic output from an otherwise clean transmitter. Careful probing of tuned circuits with a dipper is the best test for such goings on.

Since the selectivity and flywheel effect of the plate tank circuit in a Class C amplifier is the only thing standing between you and an overdose of harmonics, the tank circuit itself is a key factor in harmonic prevention.

For best selectivity, and the companion condition of minimum harmonic energy, the Q of the plate tank should be high. Like the matter of circuit efficiency versus harmonic

FRECK HAS 'EM BOTH!

"In Business Since 1928 - Serving the Amateurs"

generation, though, this is only one side of a tradeoff. High Q in a tank circuit means that the current circulating in the circuit will also be high; the circulating current in any tank with appreciable Q is equal to Q times the current going through the circuit to outside. That is, if your final is operating with a rms rf current of 100 ma (relatively low for a transmitter, since with a 600-volt supply this is only about 60 watts of rf), then if the tank circuit Q were equal to 100 the *circulating* current in the tank would be 100 x 100 ma, or 10 *amperes*. If the resistance of the coil were only 0.1 ohm, the power lost in this resistance would be I^2R, or 10 x 10 x 0.1 watts, which works out to 10 watts—or nearly half of the total power produced by the amplifier!

Reducing the tank circuit Q to 10 in the preceding example would reduce circulating current to 1 amp, and the lost power would drop to 0.1 watt; cutting Q to 1/10 its original value trimmed the loss to 1/100.

So for minimum loss in the tank circuit, Q should be low, but for minimum harmonics, Q should be high. In practice, the Q of the tank is chosen as a compromise between these conflicting requirements, and normally lies in the range from 10 to 20 (Fig. 4). A Q of 10 is about the minimum capable of providing decent harmonic rejection, but at frequencies above 21 mhz it often proves impossible to get down this low and a figure as high as 20 must frequently be accepted as the minimum possible value.

Note that these Q figures are the *loaded* Q of the complete tank circuit; don't get them mixed up with the Q ratings of the tank coil alone. The *coil's* Q must be as high

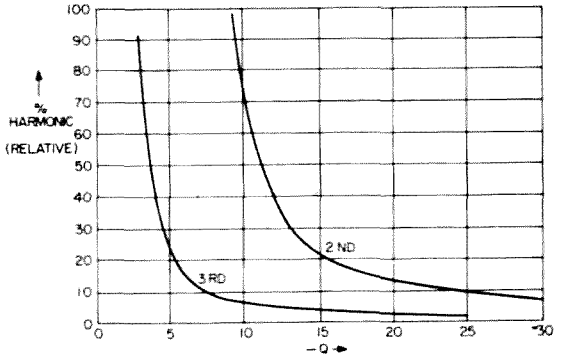

Fig. 4. Relative harmonic reduction for various plate circuit Q values.

as possible in order to keep losses down. When the entire circuit is hooked up and loaded to the desired output level, it behaves as if a resistor were connected in parallel with it. This resistor (fictional, of course) is how the output power is accounted for in the circuit equations, and the "loaded Q" about which we're talking is the ratio of this fictional resistor and the reactance at resonance.

If loaded Q is too small, harmonic problems are not the only troubles to be expected. The circuit will also prove difficult to couple to a load. Loaded Q can be increased by reducing the inductance in the circuit, or increasing the capacitance. The loaded Q of a final-amp tank will also vary with the coupling to the antenna: all calculations are based on the assumption that the amplifier is delivering its intended output power level. If more lightly loaded, Q will be higher, and if overloaded, Q will drop.

Since each tuned circuit adds additional rejection of off-frequency signals while having little effect on signals at the resonant frequency, the more tuned circuits you have, the smaller will be the harmonic content of the output. This is an excellent reason for use of antenna tuners. Harmonic filters, about which we'll have more to say a little later, are in the final analysis merely special kinds of tuned circuits.

Because additional tuned circuits offer additional harmonic rejection, any transmitter making use of frequency multiplier stages (which means, in practice, almost any transmitter except a sideband rig) should have the multipliers as early in the lineup as possible. This permits the maximum number of tuned circuits to follow them, thus attenuating the unwanted harmonics produced by the multipliers while strenghtening the desired output frequency.

The multipliers should also be operated at the lowest power level practical for them; all power gain should be achieved in straight-through stages if possible. At VHF and UHF, this is not always practical, due to the difficulties of attaining large amounts of power amplification at these high frequencies, but in hf transmitters the rules are to keep the multipliers early in the lineup, and operate them at low power.

So far we've examined only the theoretical and design considerations involved in minimizing harmonics. Construction practices, however, are of at least equal importance. Since it's impossible to avoid having at least a little harmonic energy inside a transmitter, and the theoretical cures are based on keeping it inside without permitting it to be radiated, the construction must contribute to keeping the harmonics sealed up.

One of the first steps is to employ adequate and carefully installed bypass capacitors on all signal return paths, since the unwanted harmonic energy must flow through a complete circuit and a poor bypass may permit the harmonic to find an easier path out by means of the normal output circuit. If the lead inductance of these bypass capacitors cannot be made negligible by reducing lead length to almost zero, then it should be adjusted to form a series resonant circuit to ground at the frequency of the most troublesome harmonic. This will minimize that one harmonic, at least.

A companion step, equally necessary, is to shield all rf stages adequately. To be adequate, the shielding must be complete. No gaps must exist through which harmonic energy may leak outside the rf section. This means not only that meter holes and the like must be shielded, but that all joints in the shielding enclosure be rf-tight. Finger stock or metallic sponge is usually necessary at all doors or other openings in the enclosure in order to meet this requirement.

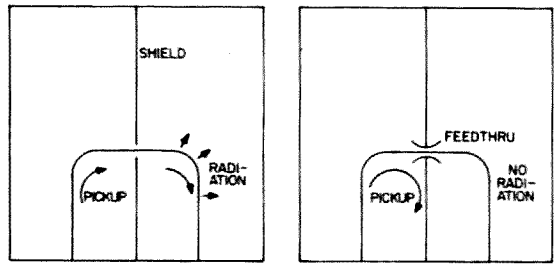

Fig. 5. How wires through shielding defeat the shield, and how to cure them.

Before shielding can be considered complete, all sources of leakage through the shielding must be plugged. This includes all wires going through the shielding (**Fig. 5**). Any lead passing through the shield should

be appropriately filtered to be certain that it carries only the *desired* energy through, and that all *undesired* energy remains trapped inside the shield. This means careful bypassing of all dc and power conductors (often using coaxial or feedthrough capacitors where the conductor passes through the shield), and appropriate filtering of signal leads.

When shielding is complete, nothing but dc and power can get into an rf enclosure, and nothing but rf at the desired output frequency can get out. What is more, the only way this rf can get out is through the antenna connector (even the antenna connector is considered to be a gap in the shielding—the shielding is kept complete by the coax shield when coax feedlines are used).

Complete shielding helps keep a transmitter from radiating harmonics through undesired ports, but does nothing in itself to reduce the quantity of harmonic energy present in the output signal. To reduce the amount of harmonic energy going out through the antenna connector, several more points of circuit design and construction should be considered:

The various stages can be coupled by any of several means. One of the most convenient, and so one of the most often used, is "capacitor coupling" where an rf choke or a tuned circuit offers high impedance to the signal in the output circuit of the preceding stage, and a capacitor provides a low-impedance route for this signal to the input circuit of the following stage. This circuit, shown in **Fig. 6**, is one of the least desirable

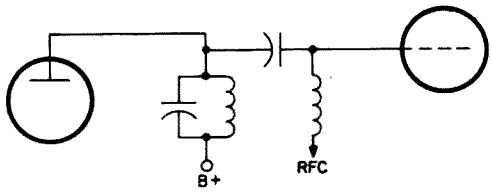

Fig. 6. Capacitor coupling between rf stages.

of all means of coupling so far as harmonics are concerned, because harmonics can couple from one stage to the next even more readily than can the desired signal when capacitor coupling is used.

Several other means also exist for coupling stages. One is "link" coupling, where the output of the preceding stage is coupled to a pickup link which is in turn connected to a second link, and the second link couples to the input of the following stage as shown in **Fig. 7**. This circuit discriminates against harmonics, because the coupling is most effective only at the frequency to which the two tuned circuits are tuned.

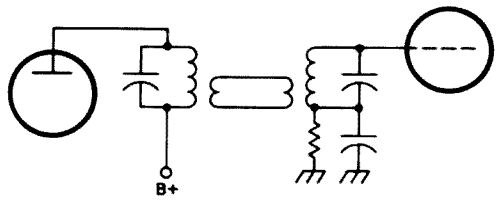

Fig. 7. Link coupling.

Another method is shielded inductive coupling, shown in **Fig. 8**. Here, the two tuned circuits are coupled directly to each other rather than through links, but an electrostatic shield between them (the "Faraday screen") blocks any capacitive transfer of harmonics from one to the other.

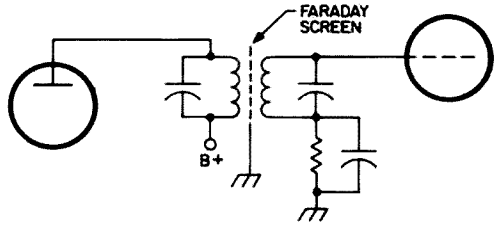

Fig. 8. Electrostatically shielded inductive coupling.

Combining these two methods gives us "shielded link" coupling, which is particularly effective against harmonic transfer. It is the same as link coupling, except that each link is electrostatically shielded from its associated coil. Unfortunately, this technique is often considered too cumbersome for ham use.

Possibly the most effective of all interstage coupling schemes, so far as harmonic rejection is concerned, is the use of a pi-network as shown in **Fig. 9**. The pi-network is, in essence, a low-pass filter and so it tends to actively filter out all harmonics. At the same time, it provides an effective coupling path for the desired signal. If designed properly, it can provide as effective coupling as any other system. However, it does require careful design or it will not transfer as much signal energy as the

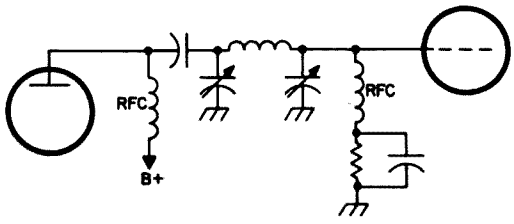

Fig. 9. Pi-network interstage coupling. Note resemblance to low-pass filter circuit.

simpler forms. This apparently the main reason it has not found more use in ham circuits, the majority of which use either capacitor or inductive coupling with no particular effort to minimize harmonics.

Once the harmonic energy reaches the output connector of the transmitter, it's still not too late to keep it from being radiated. Adding tuned circuits by means of antenna couplers will reject some harmonic energy. Most hams, however, use low-pass filters in the feedline. These filters reject all energy above their cutoff frequency.

Low-pass filters of the most common design are effective against those harmonics which cause TVI, but have little or no effect on such things as out-of-band harmonics at lower frequencies (such as the second harmonic of a 3990 khz phone signal at 7980 khz, outside any ham band).

A less common design called the "Harmoniker" consists of a half-wave trap filter, and works very much like a set of tuned circuits to pass only the fundamental signal and block all other harmonics. The disadvantage, to the operator, of such a filter is that each such filter is effective for only a single band. When the band is changed, a different filter must be put into the line. The ordinary low-pass filter, with its cutoff frequency in the neighborhood of 45 mhz, permits all signals in the hf ham bands to pass and so need not be changed for operation from 3 to 30 mhz.

No discussion of harmonic control could be complete without some examination of the final "filter" in the transmitter system—the antenna itself.

An ordinary dipole antenna is effective only for the band for which it is cut (although the ordinary dipole is also usable to a lesser degree at the third-harmonic frequency as well). Many other antenna designs share the "single-band" characteristic of the half-wave dipole. Use of such single-band antennas provides a final filtering action against unwanted harmonics, since even if they are generated and get through all the other filters and tuners up to the antenna itself, they still will not radiate efficiently.

Multi-band antennas, on the other hand, offer no such filter action. Since the ham bands are in harmonic relation to each other in the hf region (even 21 mhz is the 3rd harmonic of 7 mhz), any antenna capable of radiating efficiently on all hf ham bands must be able to radiate on at least one harmonic and frequently on several harmonics of any particular operating frequency below the 10 meter band.

Thus, when maximum control of harmonics is required, the transmitter must be designed to minimize them in the first place, then constructed with complete shielding and bypassing, operated with proper bias and drive to keep harmonics low, and connected to a single-band filter. Few ham stations require this extreme degree of control—but it *can* be achieved.

How Does the Antenna Circuit Affect the Final Stage? We all know that in any transmitter the antenna circuit plays a large part in the operation of the final rf amplifier stage. Any troubles or problems in the antenna or feedline usually manifest themselves in the form of problems in the transmitter as well. What we're setting out to discover here is *how* this interaction between antenna and final rf stage occurs, and why.

To do so, let's begin by looking not at the final rf stage, but at some earlier stage. It doesn't matter which one, because what we're going to examine is the general working principle of an rf power amplifier.

The purpose of any rf power amplifier is to accept an input signal of some sort, together with dc power from the power supply, and to produce from these two input ingredients an output signal which is a magnified copy of the input signal, identical in all respects except at a greater power level (if the amplifier happens to be modulated, the output won't be identical—but it will depend on the rf and af input signals in that case).

The input signal comes from some driving source, and the output signal is delivered to some "load." Until the output signal gets to the load, it can't be considered as "output" because it hasn't yet left the amplifying stage.

The normal load for an rf amplifier in the driver stages of a transmitter is still another rf amplifier. To get the signal from one state to the next, the two stages must be coupled together by some means. The normal means uses tuned rf circuits.

These tuned rf circuits also play a part of the role of the "load" for the driving amplifier, so far as the tube itself is concerned. The plate tank circuit has some specific value of impedance, and this value of impedance furnishes the load against which the plate current of the amplifier tube "pushes" to develop the output power.

But tuned rf circuits are rather tricky things; their impedance isn't so easy to define as is that of a simple resistor, because the impedance of a tuned rf circuit involves such things as transformer action between input and output, stray capacitance, self-inductance, and the amount of power taken out of the circuit (which acts, effectively, as resistance inserted into the circuit, and modifies the circuit Q).

For this reason, the *driven* stage influences the operation of the *driving* stage. We say that the two stages are not isolated from each other, or that they interact. We may find, for example, that adjusting the plate tank of one stage may change the plate current of some earlier stage. We are almost certain to discover that a change in the grid tuning of one stage will affect the plate tuning of the previous stage.

This interaction between coupled stages is true of all rf power amplifiers. Some circuits provide less interaction than others (notably the grounded-grid arrangement), but it's always present to some degree.

Now let's go back to the "final" stage. It still must furnish power to a load, but now the load is an antenna circuit rather than being just another amplifier stage.

The interaction, however, is still with us. Any change of impedance in the antenna circuit reflects back into the final tank

circuit of the transmitter, and affects its adjustment. The effects may be minor, or they may be catastrophic—it all depends upon the particular situation.

For any rf power amplifier to operate as designed, the operating conditions intended by its designer must be present. One of these operating conditions is the appropriate value of load impedance.

If the load impedance is too low, or too high, the amplifier won't operate as intended. Too high a load impedance prevents as much of the power getting out of the circuit as was meant to, and may cause severe damage. For example, operating a beam-power stage into an open-circuit load produces extremely large swings of plate voltage in the tank circuit. These swings affect the plate-screen voltages in such a manner as to greatly increase screen current, and it's not uncommon to find the screens of such tubes vaporized by any extended period of zero-load operation.

Too low a load impedance pulls down the Q of the final tank circuit and reduces the effective impedance seen at the plate of the tube. This removes the only limiting factor determining plate current, and again the tube may be destroyed; the main difference is that it's either the plate or the cathode which goes in this case.

These are, of course, extreme examples. But excessive swr on antenna feedlines, caused by improper feedline termination, can approach these conditions. The resulting improper operation can pop coupling or bypass capacitors, cause tuning components to arc over or melt, and burn out tube elements.

The direct means by which the antenna gets into the act at the final amplifier is because it provides the "resistance" into which the final's output power is accounted for. So long as the antenna acts as a pure resistance (or at least acts thay way at the point where the transmitter sees it), the transmitter can be adjusted to deliver its intended output power. If the transmitter is designed to operate into a 50 ohm resistive load and the antenna looks like 50 ohms of resistance, all is well.

If the transmitter expects a 50 ohm load and the antenna looks like 100 ohms of resistance, then only half as much power as expected can be transferred *at the design settings* of the transmitter.

But increasing the coupling between antenna and plate tank circuit, by either changing the number of turns of the position of the coupling link, or changing both inductance and capacitance values if the transmitter uses a pi-network output circuit, can produce the intended impedance transformation and restore normal operation.

If, on the other hand, the antenna appears to be a 25 ohm resistor, then the coupling must be decreased by moving the coupling link farther from the tank coil, using fewer turns on the link, or again changing values in a pi-net.

A more satisfactory solution to either situation is to use an external antenna coupler to transform the antenna's resistance into the 50 ohms of resistance the transmitter expects.

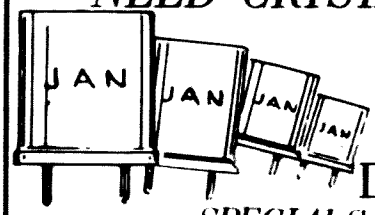
If the antenna does not look like pure resistance, but has either inductance or capacitance as well (it cannot have both L and C, because the larger will cancel out all of the smaller), things get more complicated. The reactance of the antenna will be coupled back into the final tank circuit, because the coupling means between final tank and antenna is essentially a transformer and transformers work both ways. This will detune the final tank to one side or the other of the desired frequency. When the tank is retuned to cancel out the antenna reactance, the coupling may no longer be correct, and when the coupling is changed, more detuning may occur. The net result is, at best, a compromise.

Even if the antenna itself is a pure resistance at the operating frequency, a mismatch between feedline and antenna will produce reactance in the line. The reactance may be either inductive or reactive, depending entirely upon the length of the feedline in terms of wavelength.

If the antenna itself has inductance, or capacitance, at operating frequency, then the feedline cannot match it. Line reactance in this case, though, depends upon the reactance of the antenna as well as upon feedline length and cannot easily be predicted.

No matter how much reactance is present in a feedline, it will look like a pure resistance at a series of points 1/4 wavelength apart along its length. If the antenna is a pure resistance but mismatched in resistance value to the line, these points will be every 1/4 wavelength back from the antenna. If the antenna has reactance, then the location of the first point cannot easily be predicted—but once it is found, the resistive points will recur every 1/4 wavelength back toward the transmitter.

The resistance at these points, in either case, may be very high or very low. It will never be equal to the line's rated impedance unless the line is matched to the antenna—and in this case every point along the line will show that same resistance.



For instance, a 50 ohm line connected to a 100 ohm antenna will have a vswr or 2 to 1. One quarter wavelength back from the antenna, the resistance will be 25 ohms. Another quarter-wave back, the 100 ohm antenna resistance will repeat. From there on back to the transmitter, the 25 ohm and 100 ohm values will alternate. The rule is simple in such a case; at the antenna, the antenna resistance occurs. This defines vswr as Ant/Line or Line/Ant, whichever provides a result greater than 1. Let's assume that the antenna resistance is greater than that of the line, so we use Ant/Line.

A quarter wave back, the resistance equals line resistance divided by vswr. A half wave back (two quarter waves), the resistance is that of the line multiplied by vswr. Thus at odd multiples of 1/4 wavelength, the effective resistance is that of the line divided by vswr, and at even multiples (or half-wave multiples), it is that of the line multiplier by vswr.

The same rule applies even if the antenna is reactive. The resistive points will be either at line resistance divided by vswr, or line resistance multiplied by vswr, depending upon their distance from the first resistive point and its relation to the line resistance. **Fig. 10** illustrates this rule.

Now let's consider a 50 ohm line with a 10-to-1 vswr. The pure-resistive points will be either 5 or 500 ohms. Both these values approach the extremes of short-circuit or zero-load conditions, if they appear at the

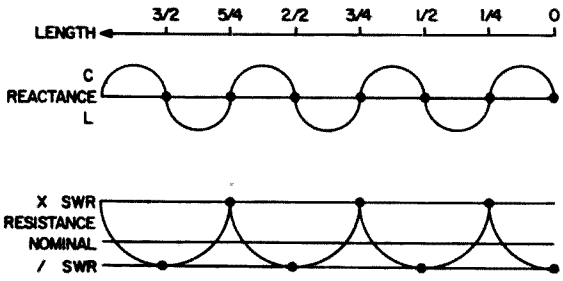

Fig. 10. Relation of feedline impedance to length of feedline.

antenna connector of our transmitter. Component damage is most likely.

In practice, we normally avoid such extremes by "pruning" the feedline so that its resistive component is somewhere near that for which the transmitter is designed, and then accepting the detuning effect of the accompanying reactance. This often works well. Again, an antenna tuner or coupler is better practice, because no detuning results.

In some cases, and with some final-amplifier output circuits, even a very small value of swr is adequate to upset circuit operation. Most affected by swr, surprisingly enough, is the popular pi-network output circuit.

The pi-network is billed as being capable of matching feedlines from 10 to 600 ohms when designed for 50 ohm operation, and this is true enough if the feedlines are resistive. However, the pi-network is a rather complex device which acts by transforming impedances, and one of its critical parameters is the capacitance present in the output side of the circuit. This parameter, in fact, establishes the value of the impedance transformation, which allows it to be used as a "loading control."

If the feedline contains reactance, the reactance may be either inductive or capacitive. If the reactance is inductive, it will cancel out a part of the output-capacitor's capacitance, and thus increase the loading. Such a feedline appears to load quite readily on a pi-net rig, and if the effect is not too severe this may be no disadvantage at all. However, a little too much inductance here may make it impossible to get loading *down* to design value.

If, on the other hand, the feedline reactance is capacitive, it will add to that of the output capacitor and thus reduce the loading. In this case, it may not be possible to make the antenna accept the full power output of the transmitter.

The cure in either case is simple; remove the reactance from the feedline. This can be done either by pruning to some different length (while this may not remove the reactance, it will certainly change it and the change may help), or by using an antenna tuner.

Now that we've seen how the antenna circuit can interact to change the operation of the transmitter's final stage, let's look again at that final stage operation. The stage was designed by someone, originally, who had some definite operating conditions in mind for it. Even if you designed it by taking a published circuit and varying things here and there to fit the content of the junk box, whoever did the original design behind the published circuit had definite operating conditions intended.

Some of these operating conditions include grid bias, grid current, driving power, plate voltage, plate current, screen voltage, screen current, and output power.

Because of the interaction of the antenna, especially in its effects upon output power, plate current, and screen conditions, almost all designs include provisions for varying the coupling between final stage and antenna. These range from a simple variable link which may be adjusted to be near the final coil (maximum coupling) or far away (minimum coupling), through the combination of a link and tuning capacitor (in this case the capacitor often serves as a coupling control and the link position is fixed), to the more complex pi network which may have one, two, or three adjustments. The coupling is intended to be adjusted as a part of the operating procedure, to provide the proper load for the final amplifier tube.

This leads immediately to the question "How do we know when coupling is correct?", but the answer is simple—correct coupling produces the design levels of input and output voltages and current, with the design level of input power and the rated output power. In other words, whenever everything else is right, you know the

coupling is right also—and if the coupling's wrong, something else will be wrong to show you.

What Happens in a Modulated Amplifier? In our previous installment, we examined the goings-on inside a modulated amplifier in considerable detail. We did not, however, delve very deeply into what happens in case various power supplies were to be suddenly short-circuited.

In some cases, of course, shorting of a power supply would simply lead to rather spectacular fireworks (particularly if the plate supply of a full kilowatt rig were to be shorted out, and to a lesser degree with the plate supply for any other device, or any screen supply).

In others, though, and especially if the power supply were intended to provide voltage rather than power, the effect upon the power supply itself might be negligible. The question then would become what would happen to the amplifier, and how would the short affect its operation.

The particular case we're studying is, of course, that cited in the FCC study list—shorting out the grid bias supply of a Class C modulated amplifier. The principles, however, apply to all supplies in which similar conditions prevail.

As we saw last time around, the bias requirements for a modulated Class C amplifier vary from moment to moment during the modulation cycle. Since the requirements are changing so rapidly, it's not possible to manually adjust the bias voltage for optimum conditions at each instant. The way around this problem is to make the bias self-adjusting, by using grid-leak bias to provide a major part of the operating bias voltage.

But when this is done, the fixed bias supply assumes a subsidiary role. Its major purpose, now, is merely to provide protection for the amplifier circuit in case the drive should be removed and so take away the grid-leak bias voltage.

When such a combination of fixed "protective" bias and grid-leak-derived "operating" bias is involved, the effect of shorting out the fixed bias supply will depend entirely upon the ratio between fixed and grid-leak bias. If the fixed bias is a small

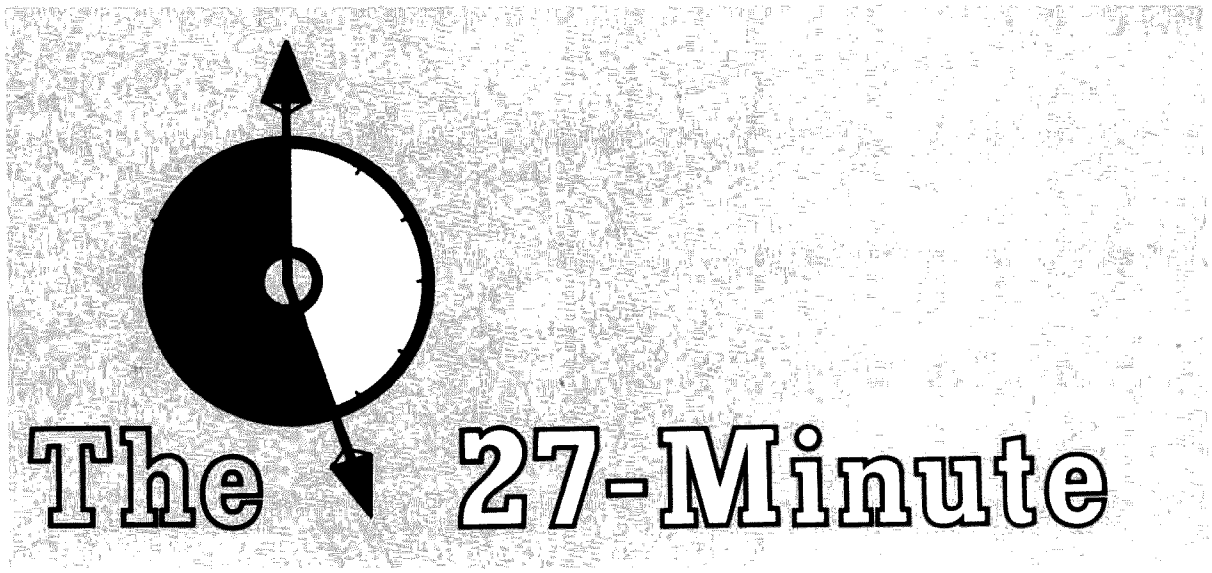
portion of the total operating grid voltage, loss of the fixed bias supply would have almost no effect upon the circuit's operation so long as drive was available to the stage. The only way, in fact, that its loss could be noted would be to remove drive and watch plate current skyrocket out of bounds.

If, on the other hand, the fixed bias provides an appreciable portion of the total operating grid voltage, with only enough extra bias derived from the grid leak to provide a measure of self-adjustment, then loss of the fixed bias supply would quite probably totally upset the amplifier's operating conditions and might even move its operation from Class C down to the Class B region. This would result in horribly distorted output, due to the drastic change in amplifier operating conditions.

Damage to the bias supply itself caused by a sudden short would depend upon the amount of current limiting designed into the supply. Most rectifiers will stand a very small momentary overload; to prevent long-term overloads, current-limiting resistors are generally connected in series with them. In supplies intended to deliver large amounts of power, these limiting resistors are small. In supplies delivering voltage but little power, the resistors are often much larger, specifically to protect against accidental shorting of the output.

The actual lack of necessity for fixed bias at all on a modulated Class C amplifier is demonstrated by the number of amplifier designs which completely omit fixed bias from all stages. Operating bias is obtained entirely from grid-leak resistors, and circuit protection is provided (if at all) by "clamp tubes" which act to drag screen voltage down to safe values if drive is lost and grid bias disappears. In an amplifier of this design, the whole question concerning bias-supply short-circuits becomes rather meaningless.



In a broader sense, though, the question still applies even if no fixed bias supply is present. Failure of the grid-leak resistor, or loss of drive, for example, can cause the operating bias to be sharply reduced or even to disappear.

When this happens, the effect upon circuit operation is catastrophic. If drive is lost, then no output can be expected and the entire transmitter is dead. If the resistor fails completely, the same situation occurs. If the resistor suddenly changes value, the transmitter may continue to operate but the operating conditions in the output stage have been completely changed and the chances of satisfactory operation are small.

The effects upon circuit components in such a case are at least as catastrophic. In a Class C amplifier, grid bias is normally the only factor limiting current in either the plate or the screen circuits. When bias disappears, both plate and screen current shoot skyward. Unless extremely rapid-action fuses are included in the circuit (and sometimes even then) the least you can expect is damage to the plate and screen milliammeters, ranging from bent needles to total burnout. If the overcurrent is allowed to persist for any appreciable period of time, and if fuses or meter burnout does not interrupt current flow, the tube itself will be damaged or destroyed. Along the way, any resistors, rf chokes, or coils in the path of the excessive current are also subject to damage.

In the absence of either fixed protective bias or clamp tubes, one scheme remains available to help protect things in case of bias loss. This is to provide a small amount of fixed bias by means of a cathode resistor. While cathode biassing is conventional practice in audio circuits, it is seldom employed in rf amplifiers for one major reason—in order for an rf power amplifier to operate properly, the cathode must be at ground potential. With a cathode bias resistor, feedback between grid and plate circuits is inevitable unless extremely effective bypassing is present. And as it happens, it's almost impossible to get bypass capacitors effective enough to work with cathode bias, since the bias resistance is relatively small and a bypass, to be effective, should have less than 1/10 and preferably less than 1/100 the impedance of the element being bypassed. Rather than attempt to develop capacitors with impedances below 0.1 ohm, most designers simply avoid cathode resistance in rf power circuits.

. . . Staff

Even with the large choice of SSB gear on the market today, there are still many amateurs who enjoy transmitting and receiving a well modulated AM carrier. This is especially true in the field of mobile radio.

A quick check of 10 meters will show that AM QSOs are available in number, and that most are from mobiles running low power. If you haven't done so lately, listen in around 29 MHz, and then sit back and recall when you used to be in there with the best of them.

For the ham who enjoys "rolling his own," AM mobile is a natural. It's even more so nowadays, what with printed circuits and ICs, because they can reduce the size of the gear. Each of us has his favorite transmitter and converter circuits, and the old reliables for antenna switching and control circuits. However, the one area that usually gets short-changed, or simply avoided, is noise limiting.

When you scan through today's ham journals, you quickly discover that the basic methods for noise suppression haven't changed too much over the years. Limiters for converters work well in general, if you're willing to pay the price of modifying the car BC set. This usually involves tearing out the detector stage, rewiring it, and then somehow stuffing the added parts into the BC set wherever you can find the space.

Just about the time I had almost given up on the idea of 10 meter mobile, because I'd have to install a series limiter, I ran across an *old* copy of Editors and Engineers Handbook. In it was a circuit that looked like it would do the job, be inexpensive to build, and above all, would be easy to install. Oldtimers will recognize the diagram as the Bishop noise limiter.

Being a shunt-type limiter, it simply hangs across the last i-f stage in the BC set. It's self-biased and automatically adjusts to the degree of modulation. The bias-circuit time constant is determined by C1 and the shunt resistance, which consists of R1 and R2 in series. The plate resistance of the last i-f tube and the capacity of C1 determine the charging rate of the limiter. It can be disabled by opening S1, which allows the bias to rise to the value of the i-f signal.

So much for the little theory involved, because as we all know, the big question is how well is it going to operate under individual circumstances? In my installation, a tube-type converter is used ahead of the car radio. With the limiter in the circuit, and engine speed at about 25 miles an hour, the noise limiting was better than I expected.

However, when the cruising speeds of 60 or 70 mph were reached, the limiter was "swamped out." It couldn't handle the incoming pulses fast enough. As you've probably guessed, the problem was quickly cured by changing the R/C time factor. This is indicated by R_X, where I paralleled two more 270 kΩ resistors. These values, of course, were needed in my limiter, and

K.J. Jewell W7SOH
2009 Tooele Place
Boise ID 83705

Mobile Limiter

the resistance will probably differ for yours. With that minor change, the limiter works as effectively at 70 mph as it does while waiting at a traffic light.

As for the title of this article, it took about 27 minutes to install and wire the parts for the limiter. I've never been able to install a series limiter in that small amount of time. The author would like to thank Bob, K7JSD, for his help during the "cuss and solder" stage of work. Bob is known locally for the crafty way in which he sweat-solders 7-pin sockets!

Parts installation couldn't be much easier. I punched a hole in the rear lip of the BC set for the 12AL5, so that the tube could be installed after the set is back in the dash. Inside the receiver is a four-lug tie strip, on which the few parts are mounted. If you buy everything new, it'll cost about $3, including the 12AL5.

Semiconductor diodes of the computer family were seriously considered at first, and we thought about using 1N658s. However, they are more expensive, and I have a strong respect for the back resistance of the 12AL5 for this kind of application.

There are many "peanut whistle" rigs on the high end of 10 meters nowadays, and it has been a pleasant experience to rediscover the fun of AM mobile. The limiter I've described will really help pull those other mobiles out of the noise level. You may even find that after you've finished reinstalling that old mobile AM gear, you can kick the sideband habit!

A LOW BAND POLICE MONITOR

With the spectrum being shared by such agencies as state police, highway patrol, and the sheriff, there should be a lot to listen to . . .

Monitoring police and emergency communications channels can provide fun and excitement. For effective monitoring, the receiver must be stable, sensitive, cover several channels, and have a squelch. There are several monitor receivers on the market ranging from about twenty dollars to well over a hundred.

Typical "Doghouse" receiver before modification.

Fortunately, for those short of money, a good receiver can be had for a few bucks and a little work – at least for the 30–50 MHz band. "Doghouse" type receivers covering this band are still found in surplus stores for around $15. These receivers are all quite similar, having been built by Motorola, or to Motorola prints by various subcontractors. These sets use 13 octal tubes. Typical model numbers are R-237/B-VR, P-8028, and FMR-13. They all have a first i-f of 4.3 MHz and a second i-f of 455 kHz. They are wideband (±15 kHz), single-channel, crystal-controlled units and nominally cover 30–40 or 40–50 MHz. Typically the front ends use 6SD7s or 6SG7s for oscillator, first mixer, and rf amplifier.

The conversion consists of building an ac power supply, connecting the local controls, and converting the crystal oscillator to a tunable type. Depending on the frequency to be monitored, the rf and mixer coils may require pruning.

First, remove the vibrator power supply by taking out the three large screws holding it to the chassis, disconnecting the red and yellow plugs, and lifting the supply off. The power supply shown in Fig. 1 is then built

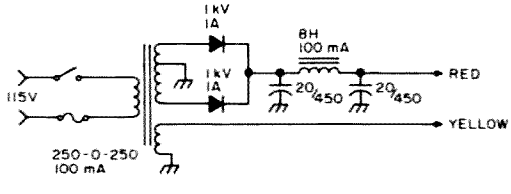

Fig. 1. Power Supply

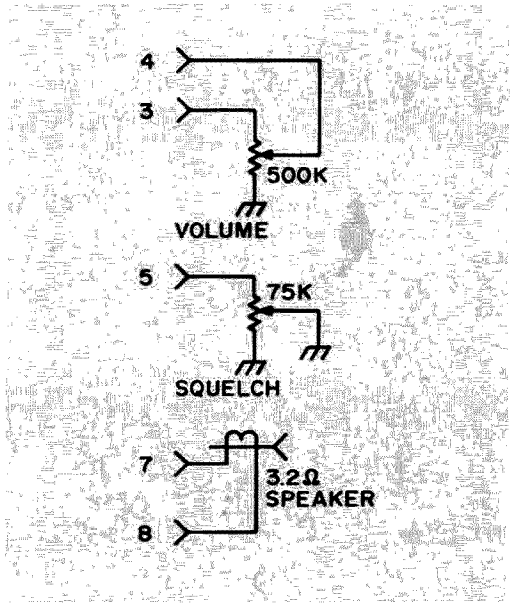

Fig. 2. Control Connections

on the chassis in the space vacated by the vibrator power supply.

The controls shown in Fig. 2 are then wired in. At this point it is advisable to "smoke-test" the set. Turn it on and check to see that the squelch and volume controls are operating properly. If you have a signal generator, feed a 4.3 MHz signal into pin 4 of the first i-f to see if all the low-frequency stages are operating properly. Frequently the conversion crystal is missing. If so, the replacement crystal frequency is 4755 kHz.

Figure 3 shows the before and after modifications made to the oscillator. At this point, a word is in order about frequency allocations. Most areas seem to group the local frequencies quite close together. In Orange County, California, for instance, most of the channels of interest lie between 45.1 and 45.7 MHz.

The front end of this set is good and broad, so rf tuning is not needed. In operation, the slug of the oscillator coil is positioned so that the tuning range of the oscillator is centered in the band of interest. A station in the center of the band is tuned in and the trimmers of L2 and T2 are peaked for best reception. Since all police transmissions are now narrowband, some improvement can be made by clipping the loading resistors from the primaries of T3, T4, and T6. The i-f's are then peaked.

If you have a 30–40 MHz receiver and want to cover the high end of the band, it will be necessary to remove one turn from L2 and T2.

Once you have the receiver working, you are ready for some serious monitoring. A well located antenna is a must. And omnidirectional coverage with vertical polarization is very desirable. A good approach is to buy a CB base station antenna and trim the elements to your frequency of interest.

This brings up the problem of how to find out what frequencies are in use in your local area, and the codes. There are two ways to do this. The first is to visit your local police or sheriff's communication center and ask. If you are too timid, you can invest in a good listening guide. There are a number commonly available.

A MOBILE

This is a description of a 50W (output), self-contained, mobile CW transmitter, for the 80-40-20 meter amateur bands. The basic idea for a simple CW rig was to have it available, and installed in the trunk of the car out of the way.

The output power is sufficient to hold regular schedules back to home base, even on long trips when you can shift to the 14 MHz band. For simplicity, plug-in coils were used for the oscillator, and a shorted coil for the output. Changing bands is not as difficult as it may first seem once the rig has been tuned up previously on each band. The cover is slipped off, the switch turned, and the coil exchanged for the other band and the knobs reset to the marked bands. The transmitter power can be turned on from a heavy-duty switch or by using a 12V dc relay from the driver's seat. A key can be mounted in the driver's compartment or strapped to the steering wheel. If a 5–10 kΩ dc relay coil is used, a low voltage battery of 15-22V will actuate it with the key, or you can tie into the car battery.

Theory

The crystal-controlled oscillator is a 12BY7 tube, and the filament heats up in 11 seconds. The oscillator has plenty of output to drive a 12DQ6 on all bands. This tube also heats very rapidly and both are more available and cheaper than quick heater filament type tubes in the 12V variety. The cathodes of both tubes are

CW TRANSMITTER

opened for keying so that the rig could be turned on just before the contacting station signs his call; thus with the tube's cathode open the oscillator does not interfere. A 100Ω resistor and .01 capacitor across the key acts as a filter.

To operate the set on 20 meters, a 7 MHz crystal is inserted in the oscillator and the plate circuit tuned to 20m works as a doubler. Normal operation on 40m would be to use a 7 MHz crystal, or you could use a 3.5 MHz crystal with the plate tuned to 40m. Both work satisfactorily. If 80m operation is intended, a set of 80m crystals that will double into the 40m CW band will work out fine.

The power supply uses a Triad toroid oscillator transformer which operates in the audio range, making filters very easy; no heavy choke is required. The whole rig and the 400-250V power supply fits on the chassis without crowding.

Construction

The transmitter and power supply are built on a California Chassis A-147, 4 x 8 x 2 in. General Radio terminals are sanded down to make a tight fit on the end of the chassis to receive the 12V from the car battery. Once these terminals are in place, the power supply parts can be fitted under the chassis and wired before building the rest of the rig.

It is best to get the power supply working before proceeding with the rest of the wiring. All parts were mounted using lock washers and then dabbed with Glyptal varnish to keep the nuts and bolts from vibrating on bumpy roads. The rig was also mounted on load mounts to help absorb some of the shock since this rig was intended to stay mounted in the car.

The oscillator plug-in coil forms were snagged from a plastic sack hanging in the radio store listed as "Calectrocorp, low-loss plastic coil forms, Cat. 1-899P." The sack with a socket and coil form was listed as 1-898-A. It took 30 turns of 28 AWG enamel for the 80m coil, 19 turns for 40m and 9 turns for 20m. The coils are terrific, they plug in and out easily, and the base will unscrew to make wiring into the prongs easier. The pi-network coil was 16 turns per inch, 1¼ in. diameter No. 1416 Air-Dux bulk coil. If your local parts store doesn't have it, it can be obtained from Western Radio, India St., San Diego, California.

Tuning

In most instances, neutralizing was not found necessary with the 12DQ6 tube; however, the circuitry was included. A wire was soldered to the bottom of the oscillator coil and the junction of the 270 pF capacitor to a feedthrough insulator. On the top side, 4 in. of 18-gage wire was soldered vertically alongside the tube. To neutralize, turn on the oscillator and remove both the plate and screen voltage

from the 12DQ6 by unsoldering the wires. Pick up the feedthrough voltage in the plate tank circuit with a grid-dipper in diode position. Now push the vertical neutralizing wire back or cut off in small nips until the feedthrough voltage reaches the minimum possible. The tank should be connected to a 50Ω noninductive resistor and peaked for 40m during this procedure by using the grid-dipper as an indicator.

Generally the best way to adjust the transmitter is to first feed it into a dummy load made up from noninductive resistors. Once tuned to this 50Ω output, the transmitter knobs are left almost untouched, and the output coax run to the coil. The braid is fastened to ground at the same place the coil is grounded and the tap moved back and forth, adjusting for maximum radiation. Closing the trunk door will have some effect on the antenna adjustment, and if possible tune with the door closed.

Battery Cable

A long length of 12-gage rubber-covered wire was used to go from the trunk to the battery. I drilled a hole in the trunk and fastened the wire with plastic clamps on the body frame to a terminal strip in the engine compartment. A 12V relay was used to operate from a toggle mounted on the dashboard for turning on the power; however, if you can run the wire inside the car, a good heavy duty 15A switch will suffice.

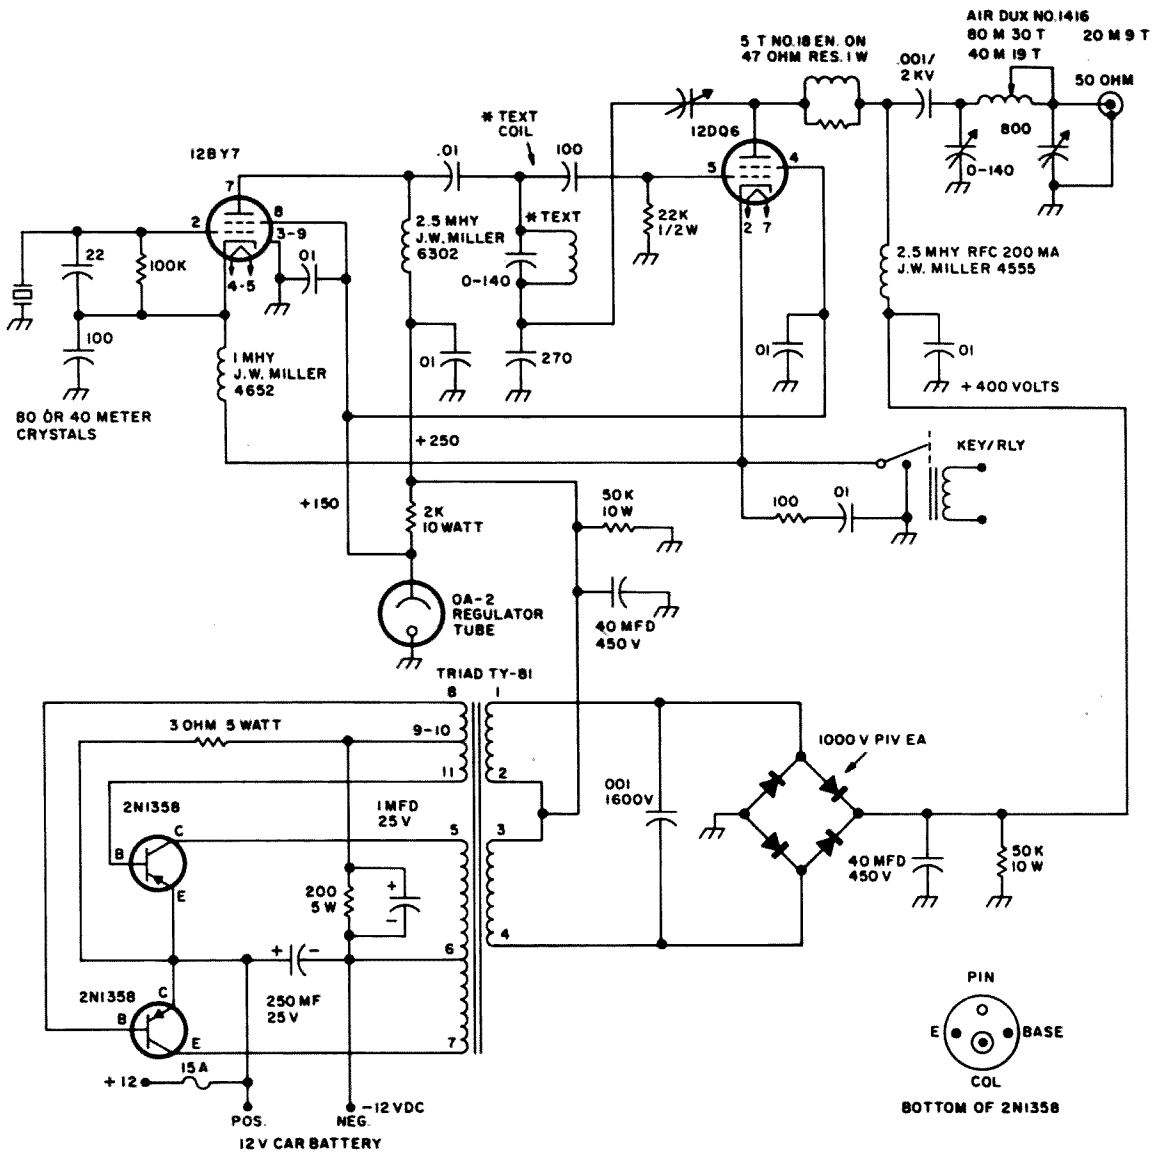

Fig. 1. Schematic.

(continued from page 13)

business mail like this. Little of this really has to be done on paper or to be physically sent in an envelope.

Picture a small typewriter with a built-in tape recorder. IBM has just such an item that we use for typesetting, so there is nothing basic left to be invented, just compromises to be made for mass production and cost-cutting. For not a lot more than the regular phone service a unit such as this could be rented and connected to the phone lines. All businesses have phones, and all but a few homes have them, so a service using this existing facility would get just about everywhere.

Your tape-typer would correct mistakes merely by back spacing and retyping over. Instead of paper it could print out on a small television screen. When the message is completed it could be addressed to a phone number and, with the push of a button, sent on its way. You want a copy? Another button would put it on a permanent tape for your file, coded for fast retrieval.

The phone would not be tied up with this system since it could operate while the phone is being used normally.

The phone lines are already all in, so all that would be needed for this system would be the tape-typers and the automatic routing equipment in the phone company exchanges.

The cost per message should be a fraction of the present cost of sending letters. And think of the saving in paper, stamps, typewriters, ribbons, and shoe leather for the postmen. Even at that, the mailmen won't be out of business by any means, for they will still have to struggle through the sleet and hail to bring you magazines and ads for Florida property.

Incoming messages would be taped and could be read at your leisure. Permanent copies can be made of important messages on tape cassettes.

If we can reduce the mail load by 80% perhaps they will be able to get the magazines through in better time? And wouldn't it be nice to be able to send letters again for 2¢ and have them delivered within seconds of being sent? That would be better than the old two deliveries a day we used to have a few years back.

A little FM unit that should be available in two surplus markets – commercial & military . . .

An FM "Best Buy"

Now that you have read all the fine articles in 73 Magazine about the fun of FM, let's talk a bit about the kind of mobile gear you are going to get. This surely deserves a lot of talk, for there are some surprises in store for the unwary.

You hear about a fine piece of gear made by Motorola or GE, and you take a look – and you generally see a monstrous contraption too big to get into the seat or the trunk of a small car – with enough tubes in it to stock an electronics distributor for life – and a circuit so complicated that some of us have been known to faint dead away at the idea of even taking off the cover! Maybe you like vast puzzles – but some of us don't.

So you try for a little one: a "handie talkie" sounds like a great idea – and in some ways it is. Take one of the older low-priced models: Has just a little power – has a headset like a telephone that gets very tiring to hang on to – has a small number of tubes, but they are in some cases so old and rare that you will have better luck searching for spares in the Egyptian pyramids than in your electronics catalog. And if you want to go ac powered you have some rare and refreshing problems in rigging up a power supply to handle your antique curiosity.

There are some modern, compact FM transceivers, and I won't knock them at all – they do a real great job – particularly when you realize that with a repeater you only need about one watt output to have a tremendous signal on the band.

But if you are like me and don't have a lot of spare cash lying around, then you will want to look at something a little lower priced. So, how would you like to get a small, compact transceiver – with power up to 50W out; that is neat, dependable, reliable – that's proved itself throughout the world for maybe 25 years, that's used in all types of state and federal aircraft and at airports, that is a proved performer in Coast Guard service, that did a bang-up job at the South Pole in Operation Deepfreeze, and that in rugged service in Alaska stood up

better than far more complex and sophisticated units? How would you like a transceiver that is old and moderately priced, but with tubes that you can still find in the 1970 Allied cataiog? And how about a unit with absolutely no trick circuits, with plain, conservative, simple design and layout for easy maintenance, a unit so simple in fact that this old horseracing writer can, with his feeble knowledge of electronics, partially understand the thing in at least a dim and groping way?

We are talking about the equipment made by Combo, in Coral Gables, Florida. And we are talking about their old tube-type equipment. (They, of course, now put out a modern line of solid state gear at the usual industrial price levels, but we are not talking about that!) My own set is an old Model 275, which was made some time before 1950. I paid the huge sum of $10 for it. It still puts out a tremendous signal – 10W out (in commercial practice they use watts *out* to measure power – 10W out is equal to maybe 20W *input*).

No, I don't own any stock in Comco. Nor do I have any of their gear to sell. (Fact is, my only contact was when I wrote for information on the Model 275 – I got a prompt answer, but no information!)

We will talk mostly about the Model 582. This is a good rig, and represents the kind of equipment they made in the past. There are lots and lots of other units they make that are suitable for amateur service – I have listed them in B, Table I. There is my Model 275, with a single channel, a 6V mobile unit. It's a handy 2 meter rig. Model 580 is good for the 6 meter band – it can have all kinds of power supplies and may have one or two channels, and an output of 25–50W. Model 680 is for the 6 meter band, and can run 1 to 4 channels with up to 100W out. A lot of power there. Model 906 is a somewhat advanced piece of gear that would also be very fine on the 6 meter band.

For the 2 meter band, we have Model 582, which gives you one to two channels, and 18–25W out. Model 682, another fine 2 meter rig, will get you up to four channels and 75W out. Model 800 is a sophisticated hand-held transceiver of the modern generation, and Model 900 is a modern transistorized portable rig – both are great on 2 meters. Also for 2 meters there is quite a range of military equipment (Table II). These have a bewildering variety of power supplies to meet military needs! The AN/FRC-70 and 70A run 50W on 2 meters, the AN/VRC Models 42, 51, 51X, and 52 run 25W on 2 meters. These are dandy rigs, and require no appreciable retuning for use at 144–148 MHz. The AN/VRC-58 is another excellent 2 meter rig.

Some of the military rigs will hit 10 meters with little trouble. The AN/FRC Models 52, 52A, and 52B will give 50-60W out. The AN/VRC 33 and 33A are single-channel mobile units (at 35W out) and won fame in Project Deepfreeze. And, for 10 meters, the AN/VRC-60 works great with a 12V power supply and gives out a good 25W.

Or maybe you would like to try the popular amateur UHF region (called 450 by FM'ers). Try Model 684 shown in Table I; you get 10 to 25W out in the 450 MHz range with no tuning problems.

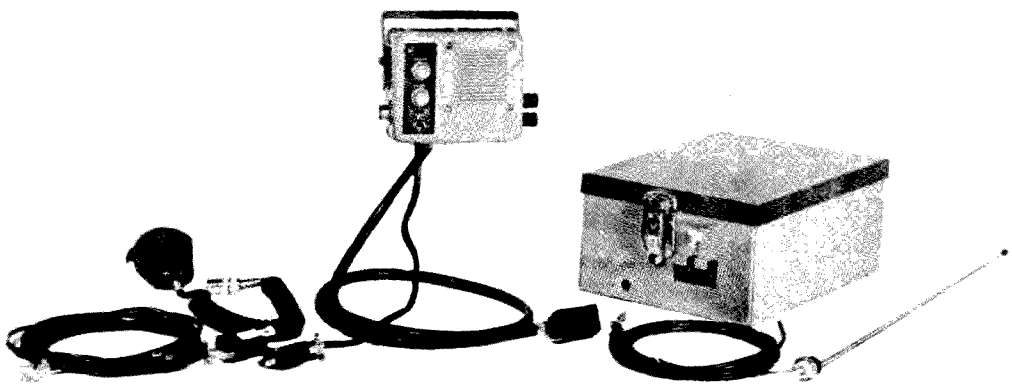

Fig. 1. The Model 582 for mobile mounting.

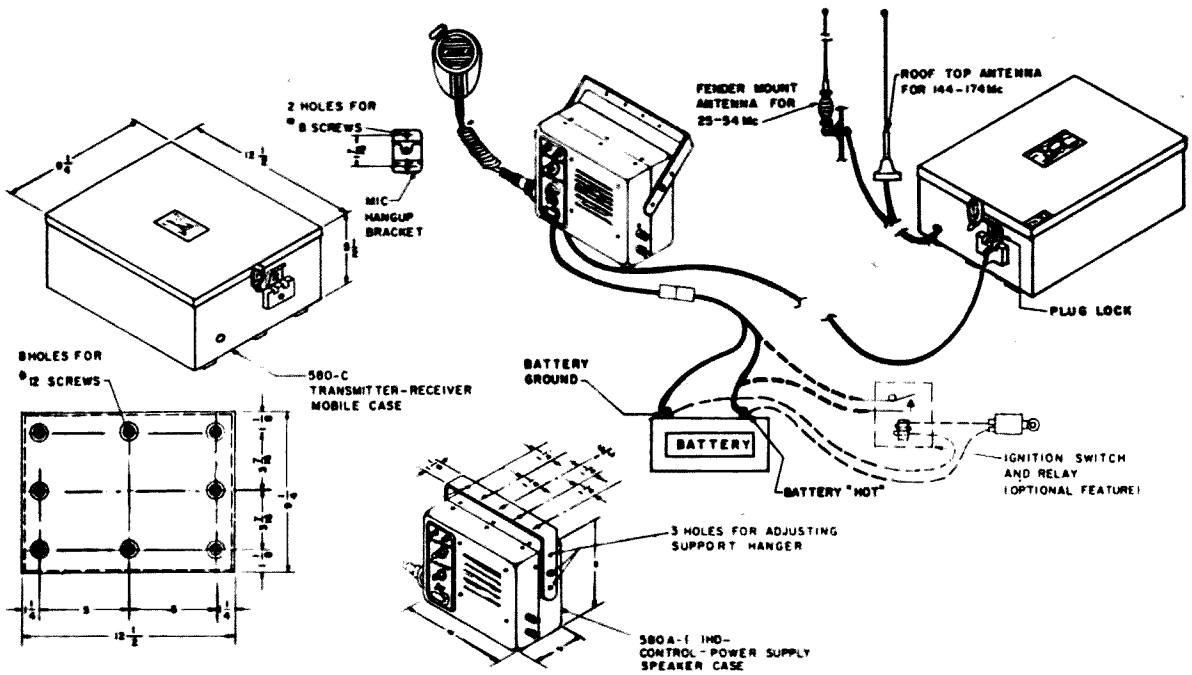

Fig. 2. Mobile hookup for the Model 582.

Let's look at some pictures. Figure 1 shows the 582 set up for mobile mounting. The little case, about the size of three reams of typewriter paper, will fit anyplace. The control head, speaker, and mike go under the dash. Figure 2 shows the mobile setup.

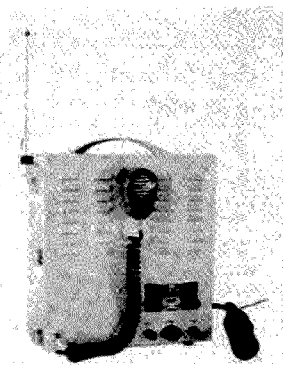

Fig. 3. Model 580/582 hand-held portable rig with an output up to 50W.

Figure 3 shows the 582 made up in a battery powered hand-held rig. This is no toy transceiver – it's got a good speaker and good mike – and a solid 50W output! It has an ac/dc power supply, is just about the handiest rig you could get hold of.

Now let's talk about the base setups. On some of those big, black rigs we mentioned earlier, you will use up half a room to store it and get some unhappy looks from the XYL if you even think of bringing it upstairs. Or, with some of the beatup, cobweb-covered battle-scarred veterans of other wars you find in surplus stores, it is best to dig a hole and give the whole thing a burial rather than to clutter up the living room or study with it.

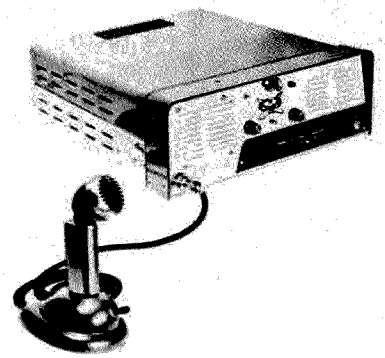

Fig. 4. The Model 582 makes an elegant base station.

But we don't have these troubles with the 582. Figure 4 shows how it makes an elegant base station, suitable for just about any room in the house.

Now, let's sort of flit through the block diagram in Fig. 5. The transmitter section multiplies 16 times for 144 MHz output and will take crystals in the 9 MHz range. Starting at the front, we have the oscillator feeding into the "phase modulator" tube. Don't let that term "phase modulator" scare

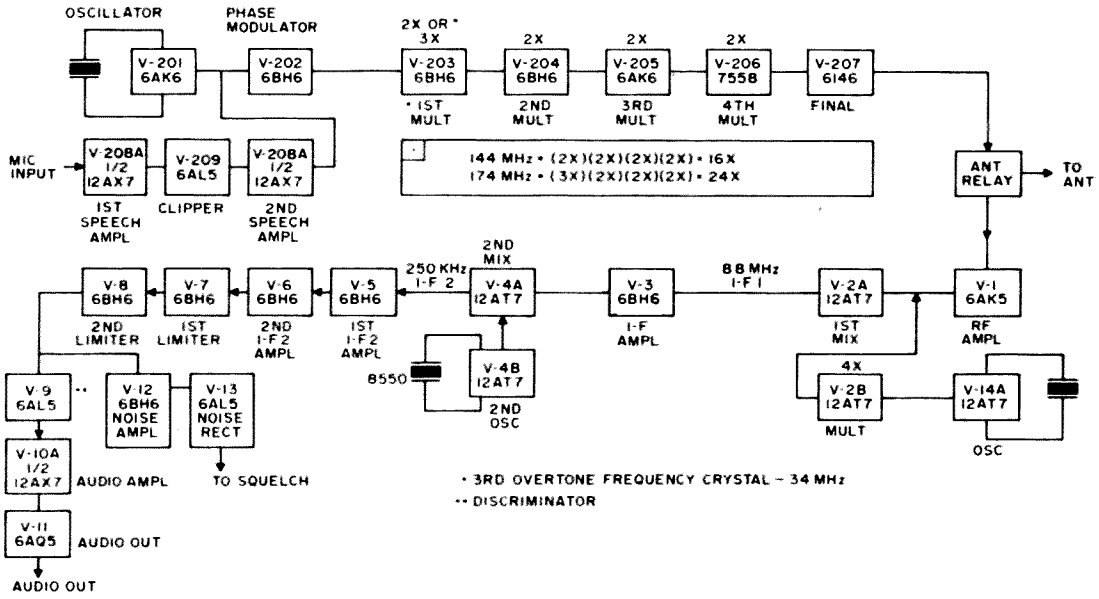

Fig. 5. Block diagram, typical 144–174 mc transmitter-receiver, 582 type.

you. All it means is that we are modulating *after* the oscillator, instead of at the oscillator. This allows a wider flexibility in control of "deviation" (Modulation) and is otherwise undetectable from frequency modulation per se.

How the thing works is not important – and I don't believe half the stuff I read about how the electrons gallop around anyhow – but it *is* important to know that any variation on the plate voltage of the modulator tube will modulate the signal, whether you want it modulated or not! So keep a sharp lookout for loose connections, intermittent shorts in capacitors, and the like.

From then on you multiply out all the way. One big advantage of FM (we call it that, anyway) is that any of the signals getting out–such as the lower harmonics–will be less likely to tear up your neighbor's TV reception. I have a friend who had nothing but neighbor trouble with a flea-power AM outfit, then he switched to a 30W FM outfit and there has been nothing but joy in the neighborhood since. By the way, he has demonstrated that he can take his 2 meter FM gear and trip our local AM repeater, and I can hear him great on my AM "Twoer"–guys with sets not a megahertz wide in front can copy him easily, too.

Now let's see what we can do with the receiver. The stuff comes in at, say, 144 MHz, and there is a stage of rf amplification. Then you have to convert it to the first i-f of 8.8 MHz. That works out to about 34 MHz in the oscillator, multiplies four times to about 136, and there we are. Only there ain't no crystal which we can afford at 34 MHz, so we buy a third overtone crystal and we're in business.

Then we have an 8.8 MHz i-f amplifier and another mixer. We feed the mixer with an 8.550 MHz signal from our crystal oscillator, and here we are at the second i-f of 250 kHz. That makes for nice selectivity. We run that through two amplification stages.

Now we hit two "limiter" stages. The idea here is to remove any AM components (such as noise) from the FM signal. The limiter chops off any high peaks and the whole thing comes out at a constant level.

Now the discriminator looms up before us. This is simply the same kind of a function as the "detector" gives us in an AM set. Next comes an amplifier and squelch circuit, designed to make life easier for the listener.

That's about all there is to it. And it's why I say that the best buy in mobile FM gear is surely the Comco Model 582 or one of its brothers. Many, many thousands of such FM models have been made – you should be able to locate one without too much trouble. Good luck!

SCIENCE FAIRS

SCIENCE EDUCATION?

by Fred Mocking
Science Editor
Radio Today

Every year, many of our grammar schools and high schools participate in "science fair" programs. The purpose of these fairs is to stimulate interest in science and to provide experience in working on science projects. Students who enter the fair do indeed gain worthwhile experience and knowledge. Many of them are fortunate in having guidance and help from parents with technical skills, or help from parents or other adults with access to unusual technical facilities. Although science fair regulations attempt to rule out this type of help, the students do, nevertheless, benefit from it. Indeed, if they were to depend solely on their own resources, many students would be unable to enter projects at all.

In spite of the positive values present in science fair activities, many thoughtful observers have questioned the basic premise that science fairs stimulate interest in science. This may astound those who have visited these fairs and who have seen the truly outstanding accomplishments of our youngsters. Yet the skeptics state that the students who receive the maximum encouragement and assistance are those who have the greatest interest and ability in science and thus who are least in need of help. Without doubt, science fairs help *them*, but what about the rest of the students? Are they better off, worse off, or unaffected by the fair?

Another question that has been raised, and moreover that has been raised by student entrants and by student winners is the fact that the "spectacular, flashy" exhibit wins. Many students believe that this is so and thus deliberately choose a project, not on the basis of their own interest or the intrinsic value of the project, but on its potential ability to impress the judges. As a consequence, we have students who will enter a laser or a Tesla coil exhibit while at the same time having no conception at all of the more elementary principles involved in electrical circuits. Thus, superficiality is encouraged at the expense of a firm understanding of basic principles. Is it not surprising that activities sponsored by educational institu-

tions should drift so far from sound educational principles?

A closer look at the science fair itself will provide some insight into this state of affairs. The primary objective of most students who enter is to win! Those who progress through the local, district, and state fairs may win one of the valuable scholarships offered and, after graduation from college, many are offered jobs by leading technical companies. In other words, the science fair program provides a simple, straightforward technique for "skimming the cream" of the scientifically able students and steering them into the technical fields that are vital to our national progress.

Now, I have no quarrel whatever with people who "skim off the cream" but I cannot accept this as a process that results in "enriching the milk." Our nation has a vital need for people in many fields who have sound backgrounds in science and we cannot afford the luxury of haphazard dependence on the relatively small group whose interests *happen* to lie in the science area.

A number of educators have become dissatisfied with science fairs for this and other reasons and have discontinued science fair activities in their schools. Other educators simply have a vague feeling that something is wrong without being able to identify it more specifically.

If we are to improve this situation, let us accept as a basic premise that *some* of the science fair activities should result in some positive return to the schools involved, that is, some benefit for all the students, and perhaps even for the teachers, who put forth so much effort towards making these fairs successful. This could lead to the following guides for new categories of science fair activities:

1. Science fair activities should, in part, result in equipment that may be used in the schools, and be relevant to the existing science curriculum. (Few teachers would complain that they already have *too much* equipment.)
2. Reduce the emphasis on *original* research by providing for projects based on hardware that simply and effectively demonstrates *known* principles incorporating student "feedback." This area has hardly been touched and in itself offers many opportunities for creative work.
3. Encourage projects that lead to simple experimental equipment that can be duplicated in classroom quantities in the school shops. Thus school laboratories can acquire equipment for each child rather than a single demonstration apparatus for the entire classroom.
4. Eliminate the need for concealing or apologizing for parental aid. If the student can bring to bear unusual resources in technical aid and equipment for the benefit of the school, why rule it out?

Other rules may be suggested, but the four items above are sufficient to show what the potentialities of science fair activities may be, once we choose our objectives properly.

Schools have been criticized for a lack of contact with important new concepts in technology and science. This problem is not the fault of educators, it is the result of a total lack of two-way communication between educators and the scientists and engineers who are familiar with current technology. Item 4, listed above, can be used to provide one framework for such communication by means of projects based on the very technology and devices that the schools would otherwise be unable to obtain. Anyone familiar with modern industry realizes that creation of a sound design takes considerable time and effort, but once such a design is created, it can be readily duplicated and made available for many users. Why should such a basic economic fact of life be excluded from our educational institutions?

Science has given us techniques to achieve almost any technological goal we may care to establish. It is time that we rethink our objectives in science education and write rules that will get us to our goals. To do any less is, to say the least, unscientific. ■

The Wichita Autopatch

Donald E. Chase WØDKU
3315 South Mt. Carmel
Wichita KS 67217

Tied in with the local repeater, this phone patch received approval from Ma Bell . . .

The purpose of this article is to give a description of the automatic telephone patch system developed for the two Wichita 2 meter repeaters. The features include mobile dial control, giving the mobile radio amateur access to the landline telephone system, as well as making other functions available to him. Many methods of remote control have been developed; most use one or more tones transmitted simultaneously or sequentially, but the method used at Wichita is a modified "Secode" type, or interrupted "single tone."

Secode systems transmit a tone of fixed frequency, interrupting the tone with no-tone pulses, created by the contacts of a standard rotary telephone dial. The decoding units sense the presence of tone and count number of "holes." When the proper sequence of pulses (holes) are received, the decoder unit will make a set of contacts for a short period (momentary "make"). A single decoder unit can be set to select from one to five functions at the remote location. We use separate functions to turn the telephone patch on and off.

The Encoder

The diagrams shown in Figs. 1 and 2 are almost self-explanatory. The output link is wound on the 88 mH toroid, using as many turns as needed. (See Fig. 3.) For high-impedance microphone circuits, 10–15 will be required; for low-impedance microphone circuits, 30 turns should be about right. The dial can be almost any type, but must have a set of open contacts that "make" when the dial is rotated "off-normal." I personally prefer the Stromberg-Carlson dial, which has extra contacts and is indicated in the drawings. To use the more conventional Western Electric or Kellogg dials, the two diodes make a simple

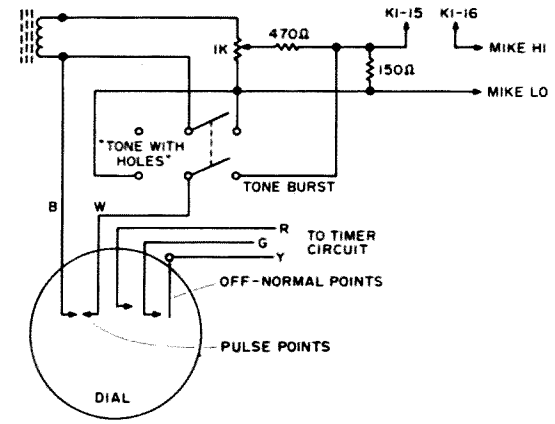

Fig. 1. Schematic showing output portion of dial encoder.

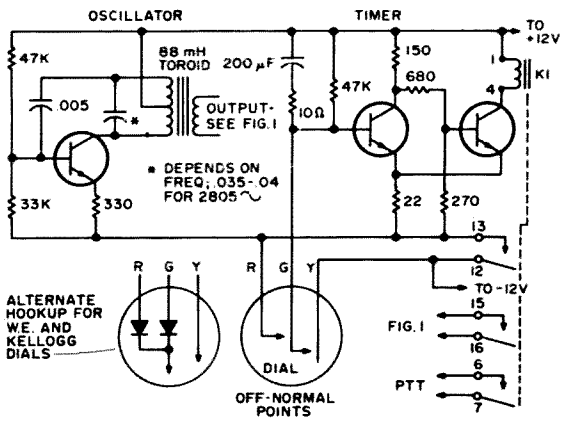

Fig. 2. Schematic showing oscillator and timer portions of tone encoder.

"and" circuit. Note: the dials from "Trimline" telephones are small and pretty, but they do not have the "off-normal" points and cannot be used. The dial pulses *must* have the correct speed and make–break ratio. Checking dial speed and make–break ratio is not difficult; one of the easiest ways is a 15 ips tape recorder with editing facilities. First, make a recording of WWV and the time ticks. At 15 ips the time ticks should be spaced 15 in. apart. This verifies your tape speed. Next, record the output of your tone encoder transmitting the digit "zero." Careful use of a grease pencil or nylon point pen to mark the on and off spaces will show you the speed of the dial and the make–break ratio. In our area, we require 10 pulses per second, and the open or "break" time should be 60%. In other words, ten pulses should take 15 in. and of the 1½ in., the pulse points on the dial should be open about 9/10 in.

Once you have one or more encoders checked out, transmit the tone through the decoder to test the pulsing relay. Adjust spring tensions, air gaps, and residual screws as necessary to obtain the same make–break ratio as transmitted by the encoder. The timer circuit holds the transmitter energized during the "interdigit" time. The 200 μF value is nominal, and can be varied. The relay shown in the diagram is a common item, but not critical. To hold the tone frequency to ±5 Hz, use of Mylar capacitors is recommended.

The Decoder

The equipment used in the channel A repeater (146.34 to 146.94 MHz, WØDKU) is a modified Secode RPD-612 with ac power supply (Fig. 4). At first, we used a single five-function selector, model 49HS-5. We later added a model 70 selector with a five-function kit added. We now have ten functions we can select and know of no reason why more selectors could not be added. An additional stage (Fig. 5) is "tapped in" at the transformer lead feeding the neon bulb. This additional stage consists of one NE-48 lamp, a pair of diodes, capacitors, resistors, a tube, and a relay with a set of normally closed contacts. This set of contacts is used to pulse the telephone network and should be tested and adjusted to give the 60% break when used with the encoder in the "tone burst" mode. The relay we used was salvaged from junk telephone relays at the local surplus emporium. Note that this relay operates

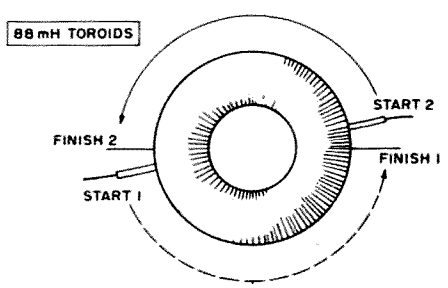

Fig. 3. Sketch shows construction of 88 mH toroids. Connect start 1 and finish 2 together (or start 2 and finish 1); this gives center tap.

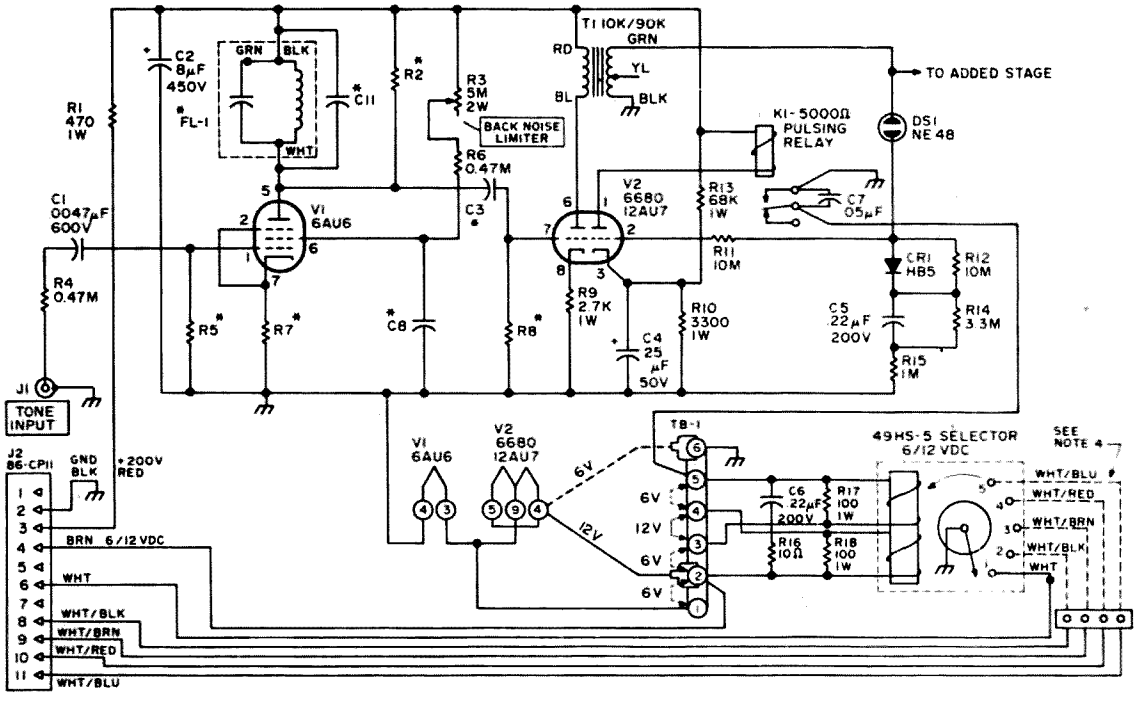

Fig. 4. RPD-612 schematic, digital decoder type 1859.

(the contacts open) any and every time that tone is transmitted to the decoder. Also note that due to the difference of tone on and tone off times in the two modes of encoder operation, the stepper unit in the selector will not operate when "tone burst" is being used.

The equipment used in the channel B repeater (146.22 to 146.82 MHz, operated by Don Pryor, WØIPB) uses the same principles but consists of a modified RPD-650 Secode decoder (transistors and mechanical selector). The Schmitt trigger stage collector load resistor (R22), 4.7K, was replaced by a relay, and the emitter resistor was reduced in value from 180Ω to 100Ω. Since the Schmitt trigger transistor (Q5) is normally conducting with no input signal, we used normally open contacts for our pulsing relay. The model 70 selector was modified by adding the five-function kit and the operation is the same as the other repeater.

Some "tinkering" was necessary to adjust spring tensions in the selector. This tightened the tolerance on the make–break ratio to prevent stepper action during "tone burst." In the RPD-612, the sensing of the make–break ratio is in the electronic circuitry. In the RPD-650 and RPD-650A, the spring tensions of the model 70 selector must be altered to obtain this effect. (The RPD-650 and RPD-650A are made to operate with 75–25 or 25–75 make–break ratio and all variations in between.)

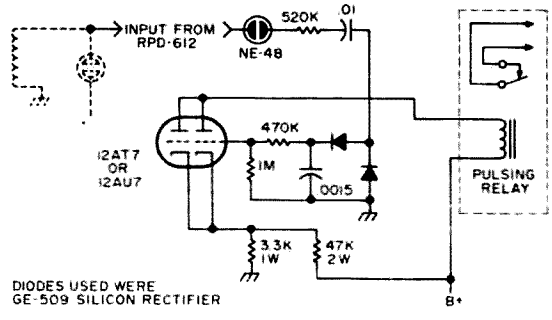

Fig. 5. Secode unit is "customized" for the Wichita repeaters by adding a separate stage for dial pulsing of the phone line.

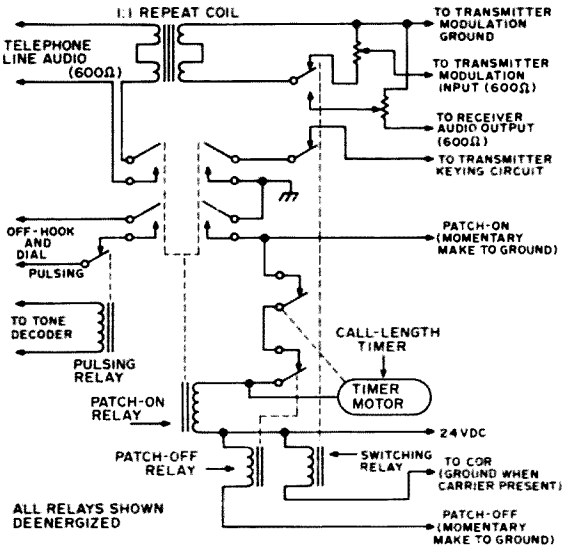
The Telephone Patch

The first reaction of radio amateurs when they see the circuit diagram (Fig. 6) is usually "where is your hybrid balance adjustment?" Quite simple, since the patch

doesn't use hybrid circuitry and is not intended for simultaneous duplex operation. Since any repeater must have some type of carrier-operated switch, we use the carrier switch to change from transmit to receive. This has a "bonus" – if the radio amateur wishes to interrupt the person on the landline, he simply pushes his microphone button and the landline is no longer transmitting. Very useful to prevent outbursts of unbecoming language from being transmitted. After all, how many two-meter mobiles are equipped for simultaneous duplex operation?



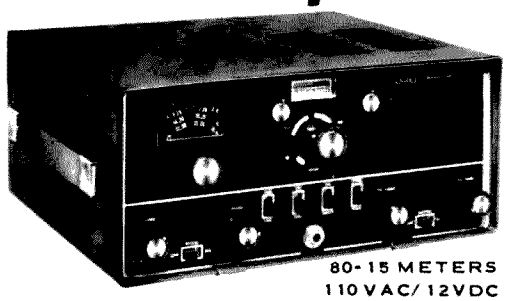


Fig. 6. Schematic diagram of Wichita autopatch radio/telephone interface.

An examination of the schematic diagram shows a pulsing relay, a switching relay, the patch-on relay and the patch-off relay, plus the call-length timer. The pulsing relay is controlled by the presence or absence of tone. The points are closed unless tone is received by the decoder. The call-length timer, a motor-driven unit, opens a set of normally closed points after a preset time interval. The timer begins operation when the patch-on relay is operated; it is returned to zero when the patch-on relay is deenergized. The patch-on relay is held on by a set of points on its own point stack. In the event of power failure the patch-on relay drops out and releases the telephone line. The call-length
